INTRODUCTION.

This volume treats of the Alvine Fluxes. It was my original intention that it should have embraced sketches of several of the other diseases which ranked as the chief causes of Sickness and Mortality among our troops during the Civil War. As the work progressed I saw that a due consideration of the questions connected with the Fluxes would occupy much more space than I had anticipated, yet still for a time hoped that I might succeed in compressing the discussion of the Camp Fevers also into this volume; but I became convinced that to do so would exclude a great deal of material relating to the Fluxes which I had collected and believed to be useful, so that I finally concluded to postpone the consideration of the Fevers, as well as the other chief camp diseases, to the Third Medical Volume of this work.

The nature of the subject will, I trust, justify this determination. Not only do the Alvine Fluxes usually cause more sickness and mortality among troops during war than any other group of diseases, but this circumstance affords a better opportunity for their study than can commonly be obtained in times of peace, so that it has heretofore happened that many of the most important accounts of these disorders, whether in ancient or modern times, have been the fruit of military experience. When I came to study carefully the documents and pathological specimens relating to this subject which had been collected by the industry of our Medical Officers during the Civil War, I formed the opinion that they were well worthy of presentation in detail; and when I began the task of interpreting them by the aid of previous experience, I was led to believe that the time had arrived when modern observations might profitably be contrasted with the records of the past, and the historical basis of the dominant opinions of the present day be subjected to careful and critical scrutiny.

This I have not hesitated to attempt. The great Medical Library which my colleague, Surgeon John S. Billings, has been enabled, by the liberal policy of the Surgeon General of the Army and the annual appropriations of Congress, to collect for the benefit of Medical Officers and of the Medical Profession of the country, has afforded me opportunities for the study of the ancient and modern literature of the subject not heretofore enjoyed by any American medical student, and I have endeavored to make the best use I could of the resources at my disposal. I have not, indeed, attempted to present a complete analysis of the literature of the Fluxes. Such a work would have occupied several years of study in addition to those already expended, and the practical results could hardly be hoped to repay

the time and labor required. But I have endeavored to trace all the more important opinions to their sources, and to weigh the observations by which they are supported.

In view of the many errors of fact scattered through the text-books, some of which have been repeated for ages by authors copying from each other, I early resolved that, so far as possible, I would cite no authority not before me when I wrote; and that, for the convenience of subsequent students, I would in every case give not only the name of the author but the edition and page to which each citation referred. In the few instances in which the incompleteness of our growing library has compelled me to depart from this rule, I have explicitly stated the fact and mentioned the actual source of my information. Large as the volume has become it would have occupied more than double the number of pages had the literary references and citations been embraced in the text. I have therefore adopted the plan of presenting all such matter, as far as possible, in foot notes, where, by using small type, much could be compressed into comparatively little space. I know that this small type is not very easy reading, but I suppose most readers will hardly trouble themselves with these references to authorities, and the future student who may undertake original investigations with regard to any of the subjects I have discussed will, I hope, forgive the type in view of the character of the matter embraced in the notes, which I trust will serve to make his task somewhat easier than mine has been.

Although the discussion of the Alvine Fluxes has occupied so much more space than I had intended, I feel quite confident that this Medical History can be completed in the Third Volume, as was originally planned. A large amount of valuable material relating to some of the other more important camp diseases has been collected, but it does not appear to me to be sufficiently complete in the case of any of them to serve as the basis of such systematic analysis as I have ventured upon in the case of the fluxes. The Third Medical Volume will therefore be limited to the presentation of these materials, together with a series of special studies based upon them, and necessarily limited by them in scope and extent. The account of the Camp Fevers and of Scurvy will require the greatest space; but even in connection with these I shall not attempt an exhaustive mode of discussion. Nevertheless the special studies which I expect to present relate to questions so intimately connected with the health and mortality not only of Armies but also, under certain circumstances, of Civil Populations, that I indulge the hope that they will be found useful by civil practitioners as well as by the medical officers of military organizations. May this prove true also of the present volume, now at last, with much labor and after serious interruptions, brought to a conclusion.

JOSEPH JANVIER WOODWARD,
Surgeon, United States Army.

March 25, 1879.

TABLE OF CONTENTS

OF

VOLUME I OF PART II

OF THE

MEDICAL AND SURGICAL HISTORY

OF THE

WAR OF THE REBELLION,

BEING THE

SECOND MEDICAL VOLUME.

CHAPTER I.—DIARRHŒA AND DYSENTERY.

	Page.
SECTION I.—STATISTICAL REMARKS	1
Total number of cases and deaths	2
Comparative number and mortality of acute and chronic cases	4
Increasing severity as the war progressed	6
Influence of Region on the number of cases and deaths	9
Influence of Season	18
Diarrhœa and Dysentery in the Confederate Armies	26
Diarrhœa and Dysentery among prisoners of war held by the Confederates	31
Diarrhœa and Dysentery among prisoners held by the United States	36
SECTION II.—REPORTS AND EXTRACTS FROM REPORTS RELATING TO DIARRHŒA AND DYSENTERY	41
DeBruler, J. P., Acting Assistant Surgeon, Hospital No. 2, Evansville, Indiana. Chronic diarrhœa	42
Storrow, S. A., Assistant Surgeon, U. S. A., Eckington Hospital, Washington, D. C. Chronic diarrhœa and dysentery	42
Schüssler, C., Surgeon 6th Indiana Vols., Hospital No. 6, Nashville, Tenn. Chronic diarrhœa	43
Penrose, R. A. F., Acting Assistant Surgeon, Satterlee Hospital, ward H, West Philadelphia. Treatment of chronic dysentery. (Cases 1 to 3)	44
Smith, J. V. C., Acting Assistant Surgeon, St. James Hospital, New Orleans, La. Treatment of diarrhœa by liquidambar styraciflua, (sweet gum)	47
Hodgen, J. S., Surgeon, U. S. V., City Hospital, St. Louis, Mo. Treatment of chronic diarrhœa by infusion of cistus canadensis—helianthemum, U. S. P.	48
Hartsuff, A., Assistant Surgeon, U. S. A., Judiciary Square Hospital, Washington, D. C. Diarrhœa treated with nitrate of silver enemata. (Cases 4 to 18)	48
Watson, A. Letter on the use of Peanuts in the treatment of diarrhœa and dysentery	59
Hartsuff, A., Assistant Surgeon, U. S. A. Report on same	50
SECTION II—Continued.	
Spencer, T. R., Surgeon, U. S. V. Report on the use of sub-nitrate of bismuth	50
Woodward, B., Surgeon 22d Illinois Vols. Chronic diarrhœa	51
Vollum, E. P., Medical Inspector, U. S. A., General Hospital, Chattanooga, Tenn. Chronic diarrhœa; its treatment by Surgeon C. N. Ellinwood, 74th Illinois	51
Gilbert, H. F., Acting Assistant Surgeon, Prison Hospital, Rock Island, Illinois. Report on the use of bromine in chronic diarrhœa and dysentery	52
Gilbert, H. F. Cases of diarrhœa and dysentery treated with bromine. From the Case Book of Rock Island Prison Hospital. (Cases 19 to 91)	53
Taylor, M. K., Surgeon, U. S. V., Keokuk Hospital, Iowa. Extract from letter on diarrhœa and dysentery	61
Wright, W. M., Surgeon 79th Pennsylvania Vols., Thomas General Field Hospital, Kingston, Ga. Chronic diarrhœa	62
Mercer, T. C., Acting Assistant Surgeon to M. Goldsmith, Surgeon, U. S. V., Jefferson Hospital, Jeffersonville, Indiana. On articles of food found in the stools of patients laboring under chronic diarrhœa	62
Coues, E., Assistant Surgeon, U. S. A. Special report on cases of acute dysentery occurring in the detachment of troops stationed at Columbia, S. C. (Cases 92 to 94)	62
Holston, J. G. F., late Surgeon of Vols. Extract from letter on diarrhœa and dysentery	66
EXTRACTS FROM REPORTS BY—	
Read, E., Surgeon 21st Indiana Vols., Camp Dix, Baltimore, Md	66
Van Slyck, DeWitt C., Surgeon 35th New York Vols., Falls Church, Va	66
Storrow, S. A., Assistant Surgeon, U. S. A., Fort Washington, Md	67

Harewood Hospital, Washington, D. C., cases 268 to 300 — 143
Douglas Hospital, Washington, D. C., cases 301 to 329 — 149
Lincoln Hospital, Washington, D. C., cases 330 to 421 — 156
Carver Hospital, Washington, D. C., cases 425 to 429 — 184
Emory Hospital, Washington, D. C., cases 430 to 433 — 186
Columbian Hospital, Washington, D. C., case 434 — 186
Stanton Hospital, Washington, D. C., case 435 — 187
Regimental Hospital, 8th Illinois Cavalry, Washington, D. C., case 436 — 187
Alexandria Hospital, 1st Division, Virginia, cases 437 to 441 — 187
Alexandria Hospital, 2d Division, Virginia, cases 442 to 463 — 188
Alexandria Hospital, 3d Division, Virginia, cases 464 to 543 — 193
L'Ouverture Hospital, Alexandria, Va., cases 544 to 558 — 204
Fairfax Seminary Hospital, near Alexandria, Va., cases 559 to 572 — 206
Field Hospital of the Army of the Potomac, cases 573 to 575 — 208
Depot Hospital, 5th Army Corps, City Point, Va., cases 576 to 581 — 208
Depot Hospital, 6th Army Corps, City Point, Va., cases 582 to 584 — 209
Hospital No. 1, Beaufort, S. C., cases 585 and 586 — 210
Hospital No. 3, Beaufort, S. C., cases 587 and 588 — 210
Hospital No. 6, Beaufort, S. C., case 589 — 211
Camp Dennison Hospital, near Cincinnati, Ohio, cases 590 to 592 — 211
General Hospital, Gallipolis, Ohio, case 593 — 212
Seminary Hospital, Columbus, Ohio, case 594 — 212
West End Hospital, Cincinnati, Ohio, cases 595 to 601 — 212
General Hospital, Madison, Ind., cases 602 to 610 — 214
General Hospital, Quincy, Ill., cases 611 to 614 — 216
Hospital of the Prison Depot, Rock Island, Ill., cases 615 to 682 — 217
Harvey Hospital, Madison, Wis., cases 683 and 684 — 227
Post Hospital, Rolla, Mo., case 685 — 227
Lawson Hospital, St. Louis, Mo., cases 686 and 687 — 227
City Hospital, St. Louis, Mo., cases 688 to 707 — 228
Hospital No. 4, Louisville, Ky., case 708 — 230
Hospital No. 9, Louisville, Ky., cases 709 and 710 — 230
Taylor Hospital, Louisville, Ky., case 711 — 231
Hospital No. 1, Nashville, Tenn., cases 712 to 775 — 231
Hospitals Nos. 2, 4, 6, and 14, Nashville, Tenn., cases 776 to 792 — 239
Hospital No. 8, Nashville, Tenn., cases 793 to 801 — 244
Hospital No. 19, Nashville, Tenn., cases 802 to 813 — 246
Hospital No. 3, Murfreesboro', Tenn., case 814 — 248
General Hospital, Tullahoma, Tenn., cases 815 to 818 — 249
General Hospital, Chattanooga, Tenn., cases 819 and 820 — 249
General Field Hospital, Chattanooga, Tenn., cases 821 to 840 — 250
Union Hospital, Memphis, Tenn., case 841 — 252
General Hospital, Natchez, Miss., cases 842 to 851 — 252
Hospital No. 3, Vicksburg, Miss., cases 852 to 859 — 254
University Hospital, New Orleans, La., case 860 — 257
Drum Barracks, California, case 861 — 257
Freedman's Hospital, Washington, D. C., cases 862 to 869 — 257
Miscellaneous—Cases 870 to 878 — 260
SECTION IV.—REMARKS ON THE PATHOLOGY AND TREATMENT OF DIARRHŒA AND DYSENTERY — 265
I. ACUTE DIARRHŒA — 266
Distinction between Diarrhœa and Dysentery — 271
Symptoms of acute diarrhœa — 272
The stools — 273
Color of the stools — 274
Calomel stools — 274
Fragments of undigested food in the stools — 277
Chemical examination of the stools — 278

Page.

SECTION IV—Continued.
Microscopical examination of the stools — 278
Low vegetable forms in the stools — 278
Mycosis intestinalis — 283
Odor of the stools — 283
Frequency and quantity of the stools — 285
Occurrence of similar cases in groups — 285
Coexistence of other diseases with diarrhœa — 286
Progress and termination — 289
Influence of Season and Region — 290
Post mortem appearances in acute diarrhœa — 292
Inflammation of the mucous and submucous coats of the intestines without ulceration — 296
Lesions observed in the small intestine — 298
Lesions observed in the large intestine — 306
Analysis of autopsies in which the lesions described were observed — 309
Lesions observed in other organs — 314
Pathological histology of the inflamed intestines — 317
Remarks on certain points in the histology of the normal intestines — 318
Histological methods employed — 321
Histological changes in the inflamed intestines — 325
II. ACUTE DYSENTERY — 336
A. Simple Inflammatory Dysentery — 348
B. Diphtheritic Dysentery — 350
The dysenteric stools — 353
Feculent matters — 353
Mucus and pus — 355

SECTION IV—Continued.

III. CHRONIC DYSENTERY ... 483
Symptoms ... 483
The stools ... 484
Ructus and flatus ... 488
Abdominal tenderness ... 492
Disordered digestion ... 492
Debility and emaciation ... 493
Other symptoms ... 494
Complications ... 495
Rheumatism and pseudo-rheumatism ... 495
Intermittent fever ... 495
Remittent and continued fevers ... 496
Peritonitis ... 497
Dropsy ... 497
Pneumonia ... 498
Chronic bronchitis and phthisis ... 498
Abscess of the liver ... 499
Perineal abscess and fistula in ano ... 499
Ulceration of the cornea ... 499
Terminations and sequelæ ... 502
Intestinal stricture or stenosis ... 504
Peritoneal bands and adhesions ... 510
Post mortem appearances in chronic dysentery ... 510
Chronic inflammation of the mucous and submucous coats of the intestines without ulceration ... 511
Chronic inflammation accompanied by follicular or other ulcers ... 515
Extensive ulceration of the large intestine, the result of sloughing during a previous attack of acute diphtheritic dysentery ... 520
Analysis of autopsies reported in previous sections ... 521
A. Cases of follicular ulceration ... 521
B. Undetermined cases ... 525
Lesions observed in other organs ... 529
The brain and its membranes ... 530
Respiratory organs ... 531
Circulatory organs ... 536
Heart-clots ... 537
Abdominal organs ... 516
Abscess of the liver ... 517
Pathological histology of chronic dysentery ... 563
Chronic non-ulcerative inflammation and cyst-formation ... 563
Follicular ulceration ... 566
Ulceration unconnected with the solitary follicles ... 573
IV. DIARRHŒA CONNECTED WITH TUBERCULAR ULCERATION OF THE INTESTINES ... 575
Post mortem appearances in tubercular ulceration of the intestines ... 579
Histological characters of the tubercular ulcers ... 586
V. CAUSES OF DIARRHŒA AND DYSENTERY ... 598
Faulty alimentation ... 599
Bad drinking water ... 599
Inorganic substances in suspension ... 600
Inorganic substances in solution ... 604
Organic matters of vegetable origin ... 609
Organic matters of animal origin ... 610
Drinking cold water ... 618
Alcoholic drinks ... 620
Errors of diet ... 622
Dyspeptic conditions and constipation ... 630
Portal congestion ... 634
Constitutional condition of those exposed ... 636
Meteorological conditions ... 639
Endemic and epidemic influences ... 643
Contagion ... 646
VI. TREATMENT OF DIARRHŒA AND DYSENTERY ... 651
Prophylaxis ... 651
General management of the sick ... 656
Diet ... 658
The drink ... 658
Tea and coffee ... 660
Alcoholic drinks ... 660
The food ... 662
Feebly nourishing liquids ... 662

SECTION IV—Continued.

Solution of albumen ... 664
Milk ... 664
Farinaceous articles of food ... 666
Fats ... 668
Nitrogenous food ... 668
Broths and soups ... 670
Beef tea and beef essence ... 670
Extract of beef ... 671
Pepsin and peptones ... 675
Raw meat ... 676
Oysters ... 677
Eggs ... 677
Cooked meat ... 678
Fresh vegetables and fruits ... 678
Venesection ... 680
Local bloodletting ... 683
Medication by the mouth ... 687
Emetics ... 689
Antimony ... 689
Ipecacuanha ... 692
Purgatives ... 703
Myrobalans, tamarinds, rhubarb ... 704
Sulphates of soda and magnesia ... 706
Cream of tartar and Rochelle salt ... 707
Castor oil ... 708
Calomel and other mercurials ... 710
Concluding remarks on the use of purgatives ... 725
Diaphoretics ... 728
Diuretics ... 733
Opium and its preparations ... 735
Other anodynes and hypnotics ... 750
Hyoscyamus ... 750
Belladonna ... 752
Stramonium and hydrocyanic acid ... 756
Cannabis indica ... 757
Chloroform ... 758
Hydrate of chloral ... 759
Bromide of potassium ... 760
Astringent and drying remedies ... 761
Vegetable astringents ... 765
Galls, tormentil, bistort, catechu, kino ... 765
Logwood, rhatany ... 766
Tannin ... 766
Gallic acid ... 768
Mineral astringents ... 769
Alum ... 769
Astringent salts of iron ... 771
Sulphate of copper ... 774
Sulphate and oxide of zinc ... 776
Nitrate and oxide of silver ... 777
Acetate of lead ... 780
Drying remedies ... 785
Medicinal earths ... 785
Subcarbonate of iron ... 785
Calcareous preparations ... 785
Bismuth ... 786
Tonics ... 795
Vegetable tonics ... 795
Gentian and chamomile ... 795
Simaruba, cascarilla, quassia, calumba and serpentaria ... 796
Peruvian bark and quinia ... 797
Other cinchona alkaloids ... 805
Salicin ... 805
Nux vomica and strychnia ... 805
Mineral tonics ... 810
Chalybeates ... 810
The mineral acids ... 810
Aromatics ... 811
Resins, balsams, oil of turpentine and camphor ... 815
Antiseptic remedies ... 821
Other modes of treatment ... 822
Arnica ... 822
Ergot ... 822
Arsenic ... 823
Bromine and iodine ... 823
Other remedies ... 824

XVI. Rectum with sloughing pseudomembrane. No. 703, Medical Section	446
XVII. Cæcum with sloughing pseudomembrane. No. 1060, Medical Section	448
XVIII. Descending colon with sloughing pseudomembrane, (reduced in size one-fourth.) No. 970, Medical Section	450
XIX. Extensive ulceration of colon. Metastatic foci in liver	452
XX. Ulceration of the colon. No. 115, Medical Section	454
XXI. Descending colon with oval ulcers. No. 136, Medical Section	456
XXII. Colon with cicatrices of diphtheritic ulcers. No. 1003, Medical Section, enlarged one-half	458
XXIII. The same, enlarged a little over three diameters	460
XXIV. Perpendicular section of colon coated with pseudomembrane. Magnified 63 diameters	461
XXV. Perpendicular section of colon showing thickening and pseudomembranous inflammation. Magnified 12 diameters	472
XXVI. Perpendicular section of colon showing a superficial, a deep and an excavating ulcer. Magnified 12 diameters	480
XXVII. Colloid cysts of colon	512
XXVIII. Transverse colon with cysts. No. 602, Medical Section	514
XXIX. Follicular ulceration of the colon. No. 206, Medical Section	516
XXX. Follicular ulceration of colon—chronic dysentery; the colon is thickened and anæmic	518
XXXI. Follicular ulceration of colon—chronic dysentery; the edges of many of the ulcers are fringed with pseudo-membrane	520
XXXII. Colon with follicular ulcers and patches of pseudomembrane. No. 279, Medical Section	522
XXXIII. Portion of descending colon with patches of pseudomembrane and small ulcers	524
XXXIV. Colon with irregular ulcers. No. 195, Medical Section	526
XXXV. Colon with cicatrices of follicular ulcers. No. 603, Medical Section. Enlarged one-half	528
XXXVI. Perpendicular section of colon showing an enlarged solitary gland which has recently ruptured. Magnified 12 diameters	568
XXXVII. Perpendicular section of colon showing commencing ulceration of the solitary glands and inflammation of the submucous coat. Magnified 63 diameters	570
XXXVIII. Perpendicular section of colon showing a follicular ulcer. Magnified 70 diameters	572
XXXIX. Perpendicular section of colon through the edges of an ulcer. Magnified 63 diameters	574
XL. Tubercular ulcer of ileum. No. 257, Medical Section	582
XLI. Peritoneal surface of the same piece	584

NOTE.—Of the foregoing illustrations the colored diagrams, Plates I and II, were executed by Mr. E. Sinclair, of Philadelphia; the chromos, Plates III, VI, VIII, XIV, XIX, XX, XXVII, XXX, XXXI, and XXXIII were executed by F. Moras, of Philadelphia, under the supervision of Mr. Hermann Faber, by whom the original water-color drawings were made. Plates IV, V, VII, XV, XVI, XVII, XVIII, XXI, XXII, XXIII, XXVIII, XXIX, XXXII, XXXIV, XXXV, XL, and XLI are reproduced from photographs of the specimens selected, made at the Museum by Mr. E. J. Ward. With the exception of Plate VII they were reproduced for the first five thousand copies of this work after the Woodbury-type process by the American Photo-relief Company, under the supervision of Mr. John Carbutt, of Philadelphia. This process, commended by Mr. ALEXANDER AGASSIZ—(No. 2, *Applications of Photography to illustrations of Natural History*, Bulletin of the Zoological Museum of Cambridge, November 30, 1871,) and subsequently employed by that naturalist for a portion of the plates of his splendid *Revision of the Echini*, Cambridge, 1872–73—was also selected by my colleague, Assistant Surgeon G. A. Otis, U. S. A., for a number of the photographic plates in the Second Surgical Volume of this work. Meanwhile, however, the Heliotype process had been made available in this country by the enterprise of James R. Osgood & Co., of Boston, under the supervision of Mr. Ernest Edwards, and as this method was found to give results which in delicacy and beauty closely approximate the Woodbury-types, while the plates, being executed in printer's ink on ordinary plate-paper, must be as permanent as the letter-press itself, it was selected for the second five thousand copies authorized by the act approved June 23, 1875. Plate VII was reproduced by the Heliotype process for both editions. Plates IX, XXV, XXVI, and XXXVI are copied from photo-micrographs, magnified 12 diameters, by Assistant Surgeon E. Curtis, U. S. A. They were etched on steel by Mr. H. Faber. Plates X, XI, XII, XIII, XXIV, XXXVII, XXXVIII, and XXXIX are fac-similes of photo-micrographs made by myself, with powers varying from 63 to 280 diameters. They were reproduced for the first five thousand copies by the Woodbury-type, and for the second by the Heliotype process, as in the case of the other photographic plates. The original negatives, and the preparations copied, are preserved in the Army Medical Museum.

Also the following copies:

Fig. A. Fac-simile of the plate representing ulceration of the ileum in the work of Bassius ---- 436
Fig. B. Fac-similes of the original cuts representing the enema apparatus of Gatinaria ---- 825

NOTE.—Of the above cuts Figs. 7, 9, 10, 11, 12, 13, 15, 16, 17, 18, 19, 20, 22, 23, 24, 28, 29, 30, 32, 37, 38, 39, 40, 41, and 42 are copied from photo-micrographs made by myself. I should have greatly preferred to have reproduced them by the Heliotype process, but economical considerations rendered this impracticable. I was therefore happy to be able to avail myself of the services of Dr. J. C. McConnell, by whose skilful hands most of the microscopical sections to be represented had been cut,* and who has executed for me a series of beautiful pen-drawings of the same size as the original photographs. From these the cuts were copied by the Photo-relief Company, No. 67 Park Place, New York. It was generally necessary to make the cuts considerably smaller than the original drawings, to which they are inferior in sharpness; yet, on the whole, I think the results equal in beauty and certainly superior in accuracy to the best I could have obtained by engraving on wood. Figs. 33, 34, 35, and 36 were reproduced in the same manner from drawings made by Dr. McConnell after photographs of the same size as the objects represented, made by Mr. E. J. Ward. Fig. 2, and the diagrams, Figs. 3, 4, 5, 6, 8, 14, 21, 25, 26, 27, and 31, were also reproduced by the Photo-relief Company from drawings by Dr. McConnell. The fac-simile of the plate of Bassius, Fig. A, was made by the same company, and Fig. B was engraved from a photograph on wood of the cuts in different editions of the work of Gatinaria.

J. J. WOODWARD, *Surgeon, U. S. A.*

*A few of the balsam-mounted sections were made by Dr. E. M. Schaeffer, and the earlier sections, mounted in gum and glycerine, by Assistant Surgeon E. Curtis, U. S. A.

THE

MEDICAL AND SURGICAL HISTORY

OF THE

WAR OF THE REBELLION (1861-'65).

PART II, VOLUME I.

BEING THE SECOND MEDICAL VOLUME.

CLASS I.—ZYMOTIC DISEASES.

CHAPTER I.—DIARRHŒA AND DYSENTERY.

SECTION I.—STATISTICAL REMARKS.

The various forms of flux which appeared among the troops during the war were recorded on the monthly reports of sick and wounded under four headings—Acute Diarrhœa, Chronic Diarrhœa, Acute Dysentery, and Chronic Dysentery. These disorders occurred with more frequency and produced more sickness and mortality than any other form of disease. They made their appearance at the very beginning of the war, not unfrequently prevailing in new regiments before their organization was complete, and although as a rule comparatively mild at first, were not long in acquiring a formidable character. Soon no army could move without leaving behind it a host of the victims. They crowded the ambulance trains, the railroad cars, the steamboats. In the general hospitals they were often more numerous than the sick from all other diseases, and rivalled the wounded in multitude. They abounded in the convalescent camps, and formed a large proportion of those discharged the service for disability. The majority of our men who were so unfortunate as to fall into the hands of the enemy suffered from these affections. Finally, for many months after the cessation of the war, and after the greater portion of the troops had returned to their homes, deaths from chronic diarrhœa and dysentery contracted in the service continued to be of frequent occurrence among them.

TOTAL NUMBER OF CASES AND DEATHS.—The total number of cases and deaths reported is shown by the following tabular statement:*

	WHITE TROOPS, FROM MAY 1, 1861, TO JUNE 30, 1866.		COLORED TROOPS, FROM JULY 1, 1863, TO JUNE 30, 1866.		TOTAL.	
	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.
Acute Diarrhœa	1,155,226	2,923	113,801	1,368	1,269,027	4,291
Chronic Diarrhœa	170,488	27,558	12,098	3,278	182,586	30,836
Acute Dysentery	233,812	4,084	25,259	1,492	259,071	5,576
Chronic Dysentery	25,670	3,229	2,781	626	28,451	3,855
Total	1,585,196	37,794	153,939	6,764	1,739,135	44,558

Large as these figures appear, they do not represent the full amount of mischief due to diarrhœa and dysentery, even in that portion of the army which is represented by the statistical tables. Certainly very many of the cases reported as enteritis or inflammation of the bowels belong to the same category, a circumstance which naturally resulted from pathological views very prevalent in the United States at the time. Table C reports 5,702 cases and 940 deaths of inflammation of the bowels among the white troops, and table CXI gives 748 cases with 193 deaths among the colored troops. It is, moreover, indisputable that a certain number of the deaths reported under various other headings were indirectly due to diarrhœa or dysentery, the fatal disorder occurring as a complication of the intestinal lesion, or its issue being determined by the general exhaustion resulting from a protracted flux. Thus, no doubt, many of the deaths ascribed to peritonitis, hæmorrhage from the bowels, jaundice, pneumonia, anæmia, debility, and some other diseases, belong to this category. The actual number of such cases cannot be estimated even approximately, and the same may be said of those which originated in the general hospitals themselves, among the patients admitted with other diseases, and among the physicians, nurses, and attendants.

The existence of these erroneously reported and unrecorded cases should not be overlooked; but even if we consider only the number of cases and deaths from diarrhœa and dysentery as actually reported, the magnitude of the evil is sufficiently apparent. The number taken on sick report with these diseases was to the total of all diseases reported about as one to every three and one-half for the white troops, and as one to every four for the colored troops. The number of deaths from diarrhœa and dysentery recorded in the tables constitute about the same proportion of the whole number of deaths from disease, viz: one to three and one-half among the white, one to four among the colored troops. These rates must be regarded as under-stating rather than exaggerating the proportion of deaths due to diarrhœa and dysentery. Assuming them to be approximately true, the total number of deaths from these disorders during the war may be computed as follows: The 37,794 deaths of white troops contained in the tabular statement above given represent the deaths from diarrhœa and dysentery out of a total number of 129,386 deaths in which

* See Part I, Volume I, Tables C and CXI.

the disease is specified. But it has been shown in the Introduction to the First Medical Volume* that 157,004 white soldiers are known to have died from disease, and that there were also 23,347 deaths the causes of which are not recorded. If it is assumed that these deaths from unrecorded causes were distributed between disease and wounds in the same proportion as those in which the cause is recorded, viz: one and seven-tenths deaths from disease to each death from wounds, 14,700 deaths from disease must be added to the number just given, making a total of 171,704 deaths from disease among white troops, 42,318 of which are simply reported as dead of disease, without the particular disease being specified. If it is supposed that the deaths from diarrhœa and dysentery among these deaths from unspecified diseases bear the same proportion they do in the case of those deaths in which the particular disease is recorded, viz: one to three and one-half, 12,091 deaths from these disorders must be added to the number already given, making a total of 49,885 deaths from diarrhœa and dysentery among the white troops. This estimate is probably considerably less than the actual number, for among the 42,318 deaths just referred to, the deaths from disease among the Union prisoners of war are included; and it will be shown hereafter that among them the deaths from diarrhœa and dysentery bore a much larger proportion to the total number of deaths than that given above.

The 6,764 deaths among colored troops embraced in the table represent the deaths from diarrhœa and dysentery out of a total of 27,499 deaths in which the disease is specified. It has been shown in the Introduction to the First Medical Volume† that the total number of deaths from disease among colored troops was 29,212; that the proportion of deaths from disease to deaths from wounds was eight and eight-tenths to one; and that there were 837 deaths from unknown causes. Dividing these deaths from unknown causes between disease and wounds in the same proportion as those from known causes, and adding, the total number of deaths from disease is found to be 29,964, of which 2,465 are not distributed among the particular diseases. If the proportion of deaths from diarrhœa and dysentery was the same among these as among the others, viz: one to four, 616 deaths must be added to the number given above, making a total of 7,380 deaths from these disorders among the colored troops. Adding this number to the deaths among white troops, as estimated above, gives 57,265 as the number of deaths from diarrhœa and dysentery in the Federal armies during the war; and even this, for the reasons indicated, must be regarded as less than the actual mortality from these diseases.

It is more difficult to approximate the number actually discharged the service from the same causes. The reports of the discharges on surgeon's certificate of disability give 17,389 white and 359 colored soldiers discharged for diarrhœa and dysentery,‡ being about one-eighth of the white and one-fifteenth of the colored soldiers discharged for disease in whose cases the nature of the disability is recorded. These figures, however, can hardly approximate the true proportion even as closely as those which represent the mortality from these diseases. The same table gives 14,500 white and 540 colored soldiers discharged for debility, and it is well known that a large number of these were suffering from chronic fluxes. So also were a certain proportion of those discharged for rheumatism, heart disease, anæmia, dropsy, inflammation of the liver, &c. Moreover, at the close of the war many thousands of diarrhœal patients, sick in the general hospitals, were mustered out of service and permitted to go to their homes, so that their names do not appear on the lists of those discharged on surgeon's certificate of disability.

---

*Page XXXVIII. †Loc. cit. ‡See Part I, Volume I, Tables CI and CXII.

To complete this general review of the losses from diarrhœa and dysentery, some allusion must be made in this place to their occurrence among the Indians employed in the United States service during the war. There were three regiments of these troops, known as the first, second, and third Indian Home Guards. These three regiments each consisted originally of about a thousand officers and men. The enlisted men and many of the officers were semi-civilized Indians, recruited as volunteers in the Indian territory. They were mustered into service during 1862: the first at Leroy, Kansas, in May; the second at Big Creek and Five Mile Run, Kansas, during June and July; and the third at Carthage, Missouri, in September. All were mustered out of service May 31, 1865. They served chiefly in Indian territory and the adjoining region. There are on file no monthly reports of sick and wounded from any of them before October, 1862, and none from the first and second before December, 1862. For a number of months in 1863, and some in 1864, there are no reports. The reports on file represent twenty-five months for the first regiment, twenty-three for the second, and thirty-one for the third. The whole number of cases of diarrhœa and dysentery embraced in the reports is 1,567. Owing to the absence of so many reports this is, of course, much less than the real number of cases, but, taking the number of cases and the mean strengths for the months reported, the annual ratios of cases per 1,000 of mean strength are 252 for the first, 308 for the second, and 387 for the third regiment.

The monthly reports of the three regiments contain only twenty-four deaths from these diseases; but others occurred, both during the months for which there are no reports, and among men sent away from the regiments to hospital. The alphabetical registers of the Surgeon General's Office, compiled from all available sources, contain in all thirty-one deaths from diarrhœa and dysentery of men belonging to these regiments. Even this number, however, is less than the truth. Still, notwithstanding the imperfection of the reports, there is enough on record to show that the proportion of cases and deaths among these Indian troops was much less than among either the colored or the white troops in the Central region; both, however, are considerably greater than the ratios for white troops in the Pacific region, which will be presently presented. Owing to the incompleteness of the reports no table of the sickness and mortality of these three Indian regiments was presented in the statistical volume of this work.

There was, besides, a small number of Indians enlisted in other organizations, as for instance in the 42d Pennsylvania Volunteers; but reports of the sickness and mortality among them are not on file.

In the considerations next to be presented, attention will be directed to the white and colored troops only, without further reference to the incomplete data relating to the Indians.

Comparative Number and Mortality of Acute and Chronic Cases.—An examination of the tabular statement already given (page 2) shows the following proportion between the number of acute and chronic cases: For white troops, one case of chronic to every six of acute diarrhœa, and one case of chronic to every nine of acute dysentery. For colored troops, one case of chronic to every nine of acute diarrhœa, and one of chronic to every nine of acute dysentery. It must, however, be remembered that the number of acute cases, especially those of acute diarrhœa, is considerably larger than the actual number of individual soldiers taken sick. It is well known that the soldier who has apparently recovered

from an attack of acute diarrhœa is peculiarly liable to subsequent inroads of the same disease, and the attacks are repeated with ever-increasing frequency, until at last the flux becomes continued and the case is reported as chronic. The same circumstance occurs in the case of acute dysentery, though here the chronic cases more frequently result from the first attack. On the other hand, chronic cases being more or less continuous, the proportion of individual soldiers to the whole number of cases is larger. This circumstance must also be borne in mind in considering the comparative mortality of the acute and chronic cases. The tabular statement under consideration gives the following results: For white troops, one death to every three hundred and ninety-five cases of acute diarrhœa; one to every fifty-seven cases of acute dysentery; one to every six of chronic diarrhœa; and one to every eight of chronic dysentery. For colored troops, one death to every eighty-three cases of acute diarrhœa; one to every seventeen of acute dysentery; one to every four of chronic diarrhœa; and one to every four and one-half of chronic dysentery.

Here it is to be remembered also that the greater part of the chronic cases occurred in soldiers previously reported with the acute forms, so that in estimating the severity of the acute cases not merely the deaths, but the number of chronic cases must be considered. Moreover, the method pursued in constructing the statistical tables contained in the First Medical Volume, from which the figures under consideration are derived, must not be forgotten. Had it been possible to obtain complete reports of sick and wounded from all the troops in the field, the field reports would have embraced all the cases sent to general hospital. It has already been shown that this, unfortunately, was not the case, and that the field reports from which the number of cases is derived were always more or less incomplete. It was not possible to supplement these reports by tabulating the cases admitted to the general hospitals on account of the frequent transfers from hospital to hospital, which would have led to a duplication of cases.* But the tables embrace all the deaths reported in general hospital as well as the deaths in the field, and the list of deaths in hospital being much more nearly complete than the report of cases in the field, it follows that the ratios just given overstate somewhat the proportion of deaths among the chronic cases.

It is to be remarked further, that while the ratios just presented may be regarded as giving an approximate notion of the greater mortality of acute diarrhœa as compared with acute dysentery, a similar value cannot be attributed to the ratios for the chronic cases. It will be shown hereafter that the greater part of the cases reported by some surgeons as chronic diarrhœa, and by others as chronic dysentery, were in fact of the same nature. Numerous records of *post-mortem* examinations show that the disease generally called chronic diarrhœa was an affection of the large intestine, which was thickened, softened, and ulcerated, or covered with pseudo-membrane, or both; that in short the lesions in the cases reported as chronic diarrhœa were identical with those observed in the cases reported as chronic dysentery. Considerable diversity of opinion has always existed as to just where the line between diarrhœa and dysentery should be drawn, and this has been the case to a certain extent even with regard to the acute as well as the chronic cases. These diversities of opinion will be commented upon in a subsequent portion of this chapter. They are alluded to at present as the reason why it has been

* See Introduction to the Medical Volume of Part I, page XXVII.

thought advisable to group diarrhœa and dysentery together in preparing the ratios which are next to be considered.

INCREASING SEVERITY OF THESE DISEASES AS THE WAR PROGRESSED.—An examination of the statistical tables contained in the First Medical Volume shows that among the white troops the severity of these diseases, as indicated by the ratio of the deaths both to cases and to mean strength, steadily increased during the progress of the war. The actual number of cases reported, and the ratio of cases to strength, was greatest during the second year of the war, but the mortality attained its maximum during the last.

Total number of cases and deaths from diarrhœa and dysentery among white troops for each year, with the annual ratio per 1,000 *of mean strength, and the number of cases to each death.*

YEAR.	Number of Cases.	Number of Deaths.	Annual ratio of cases per 1,000 of mean strength.	Annual ratio of deaths per 1,000 of mean strength.	Number of cases to each death.
May and June, 1861	9,772	4	.....	.....	.....
Year ending June 30, 1862	215,058	1,205	770	4.17	178
Year ending June 30, 1863	521,879	10,554	850	15.99	49
Year ending June 30, 1864	395,720	10,661	639	15.78	37
Year ending June 30, 1865	393,783	13,740	686	21.29	29
Year ending June 30, 1866	48,984	1,630	494	16.00	30

It will be observed that the ratio of deaths to strength during the second and third years of the war is about four times that of the first year; during the fourth year it was more than five times as great; and during the year following the war the mortality again diminished to about what it had been during the second and third years. It will also be seen, from the number of cases to each death as presented in the table, that the proportion of deaths to cases during the last year of the war was six times greater than it was during the first, and that the diminished mortality during the year following the war was due to a diminution in the number rather in the severity of the cases.

As 30,787 of the 37,794 deaths among white troops embraced in the tables occurred among the chronic cases, it is, of course, to the increased number and severity of these that we are chiefly to look for an explanation of the increasing mortality. It will be found, by comparing the number of cases to one death for each year, that the acute cases also became more severe as the war progressed. They remained, however, comparatively mild throughout. The facts are given in detail in the following table, which, shows that while the number of acute cases to each death steadily diminished during the war, and indeed during the year following the war, it was never large, the mortality at the maximum being but about one per cent. of the cases. Not so with the chronic forms; the mortality, which was about one death to twenty-nine cases during the first year, increased during the second to one death to eight and one-half cases; during the third, it was nearly one to six; during the fourth, one to four; and during the year following the war, remained one to less than five, although during this year the number of cases, and, therefore, the number of deaths, diminished greatly.

Annual number of cases and deaths among white troops from the several forms of diarrhœa and dysentery.

	Year ending June 30, 1862.		Year ending June 30, 1863.		Year ending June 30, 1864.		Year ending June 30, 1865.		Year ending June 30, 1866.	
	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.
Acute Diarrhœa	164,414	230	381,879	941	280,796	620	284,580	973	35,095	159

Total acute	196,634	568	448,369	1,908	345,072	1,862	346,050	2,221	43,457	445
No. of acute cases to one death	346.2		235.		185.3		155.8		97.7	
Chronic Diarrhœa	15,815	501	64,531	7,556	43,477	7,868	41,574	10,600	4,827	1,033
Chronic Dysentery	2,609	136	8,979	1,090	7,171	931	6,159	919	700	152
Total chronic	18,424	637	73,510	8,646	50,648	8,799	47,733	11,519	5,527	1,185
No. of chronic cases to one death	28.9		8.5		5.7		4.1		4.7	

The comparatively small number of chronic cases during the first year of the war will readily be understood. Undoubtedly cases occurred among the feeble and susceptible in a comparatively short time after they entered the service; but, as a rule, they occurred among those who were healthy and robust at the time of enlistment only after they had been exposed for a considerable time to the morbific influences of camp life, and generally not until they had suffered from repeated acute attacks. That the mortality continued so high during the year following the war resulted, undoubtedly, from the circumstance that there were so many men still in service who had contracted the disease, or at least laid the foundation for it, during the exposures of previous years.

In the case of the colored troops a similar increase in the total mortality from diarrhœa and dysentery with the progress of the war is not observed. The ratio of deaths to strength is, in fact, greatest during the first year represented by the returns, and diminished during subsequent years.

Total number of cases and deaths from diarrhœa and dysentery among colored troops for each year, with the annual ratio per 1,000 *of mean strength, and the number of cases to each death.*

Year.	Number of Cases.	Number of Deaths.	Annual ratio of cases per 1,000 of mean strength.	Annual ratio of deaths per 1,000 of mean strength.	Number of cases to each death.
Year ending June 30, 1864	46,572	2,003	1,040	43.54	23
Year ending June 30, 1865	73,976	3,235	855	36.29	23
Year ending June 30, 1866	33,391	1,526	607	26.97	22

At first sight these results would appear to invalidate the explanation of the steadily increasing mortality from diarrhœa and dysentery among the white troops which has just been offered, but, in fact, the circumstances under which most of the colored troops were first mustered into service were very different from those which surrounded the white. The recruits were largely found among the escaped slaves who accumulated in large numbers within the lines of our armies, and who had suffered much from exposure and privation before they enlisted. Moreover, from want of discipline and other causes, the hygienic conditions which at first prevailed in their camps were of the most unfavorable character. With subsequent improvement in the discipline and hygienic management of the colored troops the mortality from diarrhœa and dysentry progressively diminished. This view is confirmed by the circumstance that the total mortality from disease among the colored troops was also proportionately greatest during the year ending June 30, 1864, and subsequently diminished in like manner.* Accordingly we find, as might be expected, a much greater proportional mortality of the acute cases among the colored troops than among the white, no less than 2,860 of the 6,764 deaths among colored troops embraced in the tables being from the acute form. The following table gives the facts for each year:

Annual number of cases and deaths among colored troops from the several forms of diarrhœa and dysentery.

	Year ending June 30, 1864.		Year ending June 30, 1865.		Year ending June 30, 1866.	
	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.
Acute Diarrhœa	34,851	503	54,586	608	24,364	257
Acute Dysentery	7,215	496	12,239	584	5,805	412
Total acute	42,066	999	66,825	1,192	30,169	669
Number of acute cases to one death	42.1		56.		45.	
Chronic Diarrhœa	3,659	784	5,905	1,788	2,534	706
Chronic Dysentery	847	220	1,246	255	688	151
Total chronic	4,506	1,004	7,151	2,043	3,222	857
Number of chronic cases to one death	4.5		3.5		3.8	

It appears from this table that during the year ending June 30, 1864, there was one death out of every forty-two acute cases; during the next year, the mortality diminished to one out of fifty-six; during the year following the war, it rose again to one out of forty-five. The chronic cases, on the other hand, were less fatal during the first year represented in the reports than subsequently. One died out of every four and one-half during the year ending June 30, 1864; one out of every three and one-half during the next year; and very nearly the same proportion during the year following the war.

* See Part I, Volume I, Table CXI.

INFLUENCE OF REGION ON THE NUMBER OF CASES AND DEATHS.—Diarrhœa and dysentery were more frequent and fatal among the troops in the Central region, less so in the Atlantic, and least in the Pacific region. This difference exists in the case of the colored troops as well as the white, and is even more striking in connection with the mortality than the number of cases. Thus among the white troops the average annual mortality from July 1, 1861, to June 30, 1866, was in round numbers one per 1,000 of mean strength for the Pacific region, ten for the Atlantic region, and twenty-one for the Central region,—the proportionate mortality being ten times greater in the Atlantic than in the Pacific region, and more than twice greater in the Central region than in the Atlantic. In the case of the colored troops the average annual mortality from July 1, 1863, to June 30, 1866, was twenty-three per 1,000 in the Atlantic region, and forty per 1,000 in the Central, being nearly twice greater in the latter than in the former. The following table presents the annual results in each region for the white troops:

Annual number of cases and deaths among white troops from diarrhœa and dysentery in each of the three regions, with the ratio per 1,000 *of strength, and the number of cases to each death.*

YEAR.	ATLANTIC REGION.					CENTRAL REGION.					PACIFIC REGION.				
	Cases.	Deaths.	Ratio of cases per 1,000 of strength.	Ratio of deaths per 1,000 of strength.	No. of cases to one death.	Cases.	Deaths.	Ratio of cases per 1,000 of strength.	Ratio of deaths per 1,000 of strength.	No. of cases to one death.	Cases.	Deaths.	Ratio of cases per 1,000 of strength.	Ratio of deaths per 1,000 of strength.	No. of cases to one death.
Year ending June 30, 1862..	106,447	195	618	1.10	546.0	106,672	1,005	1,068	9.56	106.1	1,937	5	271	0.70	387.4
Year ending June 30, 1863..	231,812	2,796	810	8.91	82.9	287,498	7,750	902	23.00	37.1	2,569	8	274	0.85	321.2
Year ending June 30, 1864..	136,121	2,010	616	8.06	67.7	257,670	8,644	663	20.80	29.8	1,929	7	184	0.67	275.6
Year ending June 30, 1865..	166,240	5,634	682	19.59	29.5	224,884	8,093	706	23.38	27.7	2,659	13	225	1.10	204.5
Year ending June 30, 1866..	16,358	537	446	14.18	30.4	29,837	1,067	584	20.25	27.9	2,789	26	246	2.29	107.2

An examination of this table shows that in the Atlantic region the ratio of mortality to strength was nearly nine times greater during the second than it was during the first year of the war; during the third year it was slightly less than during the second; while during the fourth or last year of the war it was more than twice as great as during the second and third, approaching, in fact, the mortality rate of the Central region. The year following the war the ratio again fell off, yet continued higher than it had been before the last year. The causes of the heavy mortality in the Atlantic region during the year ending June 30, 1865, are undoubtedly to be sought, in part at least, in the exposures and privations of the severe military operations of the year, particularly those of the army of the Potomac, which operated most of the year in the unhealthy region before Petersburg, Virginia, and contributed by far the greatest portion of the cases and deaths.

In the Central region the mortality was large from the first, amounting to nearly one per cent. of the strength for the first year; during the second year this rate was more than doubled, but afterward there was no material increase. The ratio for the third year was three per 1,000 less than that of the second, and the increase during the last year of the war only made the ratio a fraction greater than that attained during the second year. The increased mortality for the whole army, already mentioned as characterizing the last year of the war, was therefore chiefly due to the increase in the Atlantic region.

During the year following the war the ratio of mortality in the Central region diminished a little, but not quite so much as in the Atlantic region.

In the Pacific region the mortality was very small throughout. It will be observed, however, that the ratio is doubled during the year following the war. The increase was due chiefly to the transfer of troops from the other regions. Twelve of the twenty-six deaths are known to have been among soldiers thus transferred.

The following table presents the annual results in each region for the colored troops:

Annual number of cases and deaths from diarrhœa and dysentery among colored troops in the Atlantic and Central regions, with the ratio per 1,000 *of strength, and the number of cases to each death.*

Year.	Atlantic Region.					Central Region.				
	Cases.	Deaths.	Ratio of cases per 1,000 of strength.	Ratio of deaths per 1,000 of strength.	No. of cases to one death.	Cases.	Deaths.	Ratio of cases per 1,000 of strength.	Ratio of deaths per 1,000 of strength.	No. of cases to one death.
Year ending June 30, 1864	11,551	108	836	7.56	107.0	35,021	1,895	1,131	59.73	18.5
Year ending June 30, 1865	26,375	987	923	31.23	26.7	47,601	2,248	865	39.07	21.2
Year ending June 30, 1866	3,961	196	421	19.49	20.2	29,430	1,330	645	28.56	22.1

This table shows that in the Atlantic region the mortality followed the same general course among the colored troops as among the white. It was least during the first year represented in the tables, increased considerably during the next year, and materially diminished during the year following the war. It is in the Central region that the great mortality occurred during the year ending June 30, 1864, which determines the anomalous feature in the progress of the mortality from diarrhœa and dysentery among the colored troops, which was commented upon in a previous paragraph (page 8), and it is well known that it was in this region that the causes then mentioned existed in the highest degree. In the Central region also the mortality remained comparatively high during the year following the war; and it is worthy of note that an examination of the sick reports shows that it was higher among the colored troops in the state of Texas than in any other portion of the Central region. In that state the average strength of the colored troops during the year ending June 30, 1866, as represented by the sick reports, was 10,553; the number of deaths from diarrhœa and dysentery was 401, or 38 per 1,000 of mean strength. The average mean strength of the colored troops in the rest of the Central region, as represented by the reports, was 36,009, among whom there were 929 deaths from diarrhœa and dysentery, or 26 per 1,000 of mean strength. The chief cause of the greater mortality in the state of Texas was the existence of a well-marked scorbutic taint, and will be a subject of further comment hereafter. It should, however, be stated here that the mortality from the same diseases among the white troops in Texas during this year, though large, was not greater than in the rest of the Central region.

In Circular No. 6 the opinion was expressed that cases of diarrhœa and dysentery were more fatal when treated in Southern than in Northern hospitals, and the attempt was made to give a numerical expression to this opinion, especially with regard to the chronic cases treated in the general hospitals during the second year of the war. (Circular

No. 6, page 122.) Subsequent investigation has shown that the figures there given can only be regarded as rough approximations. They were deduced from the monthly reports of sick and wounded by comparing the number of deaths with the number of admissions, without taking into account the transfers to other hospitals, the total number of which only was given in the reports, without specifying the diseases of the men transferred. Hence, the proportion of cases to deaths appears larger than it really was.

The original registers of the general hospitals having been turned in to the Surgeon General's Office after the close of the war, afford the means of obtaining more accurate information; but it would involve a greater amount of clerical labor than it has been found possible to devote to the purpose to make an exhaustive analysis of their contents. Under the circumstances it has only been feasible to select a few representative hospitals out of the whole number. The original registers of these have been gone over name by name, and from the total number of cases of diarrhœa and dysentery admitted all transfers to other hospitals have been subtracted, and the number of deaths and discharges on surgeon's certificate of disability compared with the remainder, thus giving a just notion of the relative mortality from the diseases under consideration in each of the hospitals named. The results thus obtained are of course not so satisfactory as if it had been possible to treat the records of all the general hospitals in the same manner, still they are sufficient to show that while the opinion expressed in Circular No. 6 is in a general way correct, other circumstances than the influences of latitude gravely modified the results.

In the Atlantic region the records of seventeen general hospitals have been analyzed in the manner just indicated, with the following results:

The records of the hospital at Burlington, Vermont, extend from April 23, 1862, to July 4, 1865. During this period 412 admissions from diarrhœa and dysentery were recorded, of whom 14 were transferred to other hospitals, 13 died, and 35 were discharged on surgeon's certificate of disability. Deducting the cases transferred from the whole number of admissions, there was one death out of every 30.6 cases treated in the hospital, and one discharge out of every 11.4 cases.

The records of the hospital at Brattleboro', Vermont, extend from January, 1862, to August 31, 1865. During this period 802 admissions from diarrhœa and dysentery were recorded, of whom 317 were transferred to other hospitals, 39 died, and 21 were discharged for disability. Omitting the number transferred, there was one death to every 12.5 cases, and one discharge to every 23.1 cases.

The records of the Cony hospital, Augusta, Maine, extend from June 3, 1864, to November 29, 1865. During this period 408 admissions from diarrhœa and dysentery were recorded, of whom 19 were transferred to other hospitals, 27 died, and 98 were discharged for disability. Omitting the number transferred, there was one death to every 14.4 cases, and one discharge to every 4.1 cases.

The records of the Knight hospital, New Haven, Connecticut, extend from June 9, 1862, to November, 1865. During this period 757 admissions from diarrhœa and dysentery were recorded, of whom 106 were transferred to other hospitals, 37 died, and 139 were discharged for disability. Omitting the number transferred, there was one death to every 17.6 cases, and one discharge to every 4.7 cases.

The records of the Lovell hospital, Portsmouth Grove, Rhode Island, extend from

July, 1862, to October, 1865. During this period 943 admissions from diarrhœa and dysentery were recorded, of whom 270 were transferred to other hospitals, 95 died, and 134 were discharged for disability. Omitting the number transferred, there was one death to every 7.1 cases, and one discharge to every 5 cases.

The records of the Ira Harris hospital, Albany, New York, extend from June 21, 1862, to December 30, 1865. During this period 523 admissions from diarrhœa and dysentery were recorded, of whom 75 were transferred to other hospitals, 33 died, and 189 were discharged for disability. Omitting the number transferred, there was one death to every 13.6 cases, and one discharge to every 2.3 cases.

The records of the McDougall hospital, Fort Schuyler, New York harbor, extend from October 10, 1862, to September 16, 1865. The hospital was closed temporarily from January 20 to May 24, 1864. During the whole period 2,193 admissions from diarrhœa and dysentery were recorded, of whom 691 were transferred to other hospitals, 207 died, and 270 were discharged for disability. Omitting the number transferred, there was one death to every 7.3 cases, and one discharge to every 5.6 cases.

The records of the De Camp hospital, David's Island, New York harbor, extend from May 22, 1862, to December 2, 1866. During this period 3,969 admissions from diarrhœa and dysentery were recorded, of whom 1,148 were transferred to other hospitals, 522 died, and 200 were discharged for disability. Omitting the number transferred, there was one death to every 5.4 cases, and one discharge to every 14.1 cases.

The records of the Mower hospital, Philadelphia, Pennsylvania, extend from December 24, 1862, to November 15, 1865. During this period 2,671 admissions from diarrhœa and dysentery were recorded, of whom 509 were transferred to other hospitals, 106 died, and 161 were discharged for disability. Omitting the number transferred, there was one death to every 20.4 cases, and one discharge to every 13.43 cases.

The records of the Satterlee hospital, West Philadelphia, extend from June, 1862, to September, 1865. During this period 2,128 admissions from diarrhœa and dysentery were recorded, of whom 270 were transferred to other hospitals, 124 died, and 337 were discharged for disability. Omitting the number transferred, there was one death to every 14.9 cases, and one discharge to every 5.5 cases.

The records of the Jarvis hospital, Baltimore, Maryland, extend from June 20, 1862, to July 25, 1865. During this period 1,637 admissions from diarrhœa and dysentery were recorded, of whom 792 were transferred to other hospitals, 122 died, and 63 were discharged for disability. Omitting the number transferred, there was one death to every 6.9 cases, and one discharge to every 13.4 cases.

The records of the Harewood hospital, Washington, D. C., extend from September, 1862, to May 1, 1866. During this period 2,803 admissions from diarrhœa and dysentery were recorded, of whom 991 were transferred to other hospitals, 186 died, and 122 were discharged for disability. Omitting the number transferred, there was one death to every 9.7 cases, and one discharge to every 14.9 cases.

The records of the Lincoln hospital, Washington, D. C., extend from December 23, 1862, to August 8, 1865. During this period 2,937 admissions from diarrhœa and dysentery were recorded, of whom 1,090 were transferred to other hospitals, 244 died, and 129 were discharged for disability. Omitting the number transferred, there was one death to every 7.6 cases, and one discharge to every 14.3 cases.

The records of the hospital at Annapolis, Maryland, extend from January 20, 1861, to May 21, 1865. During this period 5,305 admissions from diarrhœa and dysentery were recorded, of whom 1,733 were transferred to other hospitals, 1,055 died, and 113 were discharged for disability. Omitting the number transferred, there was one death to every 3.5 cases, and one discharge to every 31.6 cases.

The records of the Hampton hospital, Fortress Monroe, Virginia, extend from August 18, 1862, to May 1, 1866. During this period 5,258 admissions from diarrhœa and dysentery were recorded, of whom 1,668 were transferred to other hospitals, 806 died, and 303 were discharged for disability. Omitting the number transferred, there was one death to every 4.5 cases, and one discharge to every 11.8 cases.

The records of the Foster hospital, Newbern, North Carolina, extend from August 22, 1862, to October 31, 1865. During this period 2,289 admissions from diarrhœa and dysentery were recorded, of whom 1,115 were transferred to other hospitals, 133 died, and 41 were discharged for disability. Omitting the number transferred, there was one death to every 8.8 cases, and one discharge to every 28.6 cases.

The records of the Hilton Head hospital, South Carolina, extend from March 1, 1862, to October 12, 1866. During this period 1,781 admissions from diarrhœa and dysentery were recorded, of whom 449 were transferred to other hospitals, 185 died, and 111 were discharged for disability. Omitting the number transferred, there was one death to every 7.2 cases, and one discharge to every 12 cases.

The records of fourteen hospitals situated in the Central region have been analyzed in the same manner, with the following results:

The records of the Harvey hospital, Madison, Wisconsin, extend from October 27, 1863, to September 4, 1865. During this period 779 admissions from diarrhœa and dysentery were recorded, of whom 103 were transferred to other hospitals, 32 died, and 284 were discharged for disability. Omitting the number transferred, there was one death to every 21.1 cases, and one discharge to every 2.4 cases.

The records of the hospital at Keokuk, Iowa, extend from April 20, 1862, to September 30, 1865. During this period 1,169 admissions from diarrhœa and dysentery were recorded, of whom 188 were transferred to other hospitals, 110 died, and 55 were discharged for disability. Omitting the number transferred, there was one death to every 8.9 cases, and one discharge to every 17.8 cases.

The records of the Benton Barracks hospital, St. Louis, Missouri, extend from July, 1861, to May, 1865. During this period 2,794 admissions from diarrhœa and dysentery were recorded, of whom 516 were transferred to other hospitals, 154 died, and 186 were discharged for disability. Omitting the number transferred, there was one death to every 14.7 cases, and one discharge to every 12.8 cases.

The records of the Marine hospital, St. Louis, Missouri, extend from May 4, 1862, to June, 1866. During this period 920 admissions from diarrhœa and dysentery were recorded, of whom 103 were transferred to other hospitals, 100 died, and 97 were discharged for disability. Omitting the number transferred, there was one death to every 8.2 cases, and one discharge to every 8.4 cases.

The records of the Jefferson Barracks hospital, St. Louis, Missouri, extend from April 30, 1862, to November 21, 1865. During this period 6,225 admissions from diarrhœa and dysentery were recorded, of whom 1,480 were transferred to other hospitals, 912 died,

and 1,334 were discharged. Omitting the number transferred, there was one death to every 5.2 cases, and one discharge to every 3.6 cases.

The records of the hospital at Cairo, Illinois, extend from April 21, 1861, to June 19, 1865. During this period 2,344 admissions from diarrhœa and dysentery were recorded, of whom 175 were transferred to other hospitals, 293 died, and 90 were discharged for disability. Omitting the number transferred, there was one death to every 7.4 cases, and one discharge to every 24.1 cases.

The records of the Camp Dennison hospital, near Cincinnati, Ohio, extend from November, 1862, to October 27, 1865. During this period 2,439 admissions from diarrhœa and dysentery were recorded, of whom 273 were transferred to other hospitals, 79 died, and 431 were discharged for disability. Omitting the number transferred, there was one death to every 27.4 cases, and one discharge to every 5 cases.

The records of the hospital at Madison, Indiana, extend from June 24, 1863, to August, 1865. During this period 1,514 admissions from diarrhœa and dysentery were recorded, of whom 369 were transferred to other hospitals, 74 died, and 165 were discharged for disability. Omitting the number transferred, there was one death to every 15.5 cases, and one discharge to every 6.9 cases.

The records of the Jefferson hospital, Jeffersonville, Indiana, opposite Louisville, Kentucky, extend from February 23, 1864, to December, 1865. During this period 3,036 admissions from diarrhœa and dysentery were recorded, of whom 1,488 were transferred to other hospitals, 213 died, and 18 were discharged for disability. Omitting the number transferred, there was one death to every 7.3 cases, and one discharge to every 86 cases.

The records of the Brown hospital, Louisville, Kentucky, extend from September 3, 1862, to July 19, 1865. During this period 3,117 admissions from diarrhœa and dysentery were recorded, of whom 1,252 were transferred to other hospitals, 254 died, and 190 were discharged for disability. Omitting the number transferred, there was one death to every 7.3 cases, and one discharge to every 9.8 cases.

The records of the Cumberland hospital, Nashville, Tennessee, extend from May 17, 1864, to April 27, 1866. During this period 3,910 admissions from diarrhœa and dysentery were recorded, of whom 2,185 were transferred to other hospitals, 264 died, and 110 were discharged for disability. Omitting the number transferred, there was one death to every 6.5 cases, and one discharge to every 15.7 cases.

The records of the Gayoso hospital, Memphis, Tennessee, extend from March 3, 1863, to November 25, 1865. During this period 1,726 admissions from diarrhœa and dysentery were recorded, of whom 457 were transferred to other hospitals, 313 died, and 142 were discharged for disability. Omitting the number transferred, there was one death to every 4 cases, and one discharge to every 8.9 cases.

The records of the Barracks hospital, New Orleans, Louisiana, extend from January 1, 1863, to November 26, 1865. During this period 3,540 admissions from diarrhœa and dysentery were recorded, of whom 537 were transferred to other hospitals, 560 died, and 359 were discharged for disability. Omitting the number transferred, there was one death to every 5.2 cases, and one discharge to every 8.1 cases.

The records of the Marine hospital, New Orleans, Louisiana, extend from August 9, 1862, to June 29, 1865. During this period 3,268 admissions from diarrhœa and dysentery were recorded, of whom 779 were transferred to other hospitals, 632 died, and 457 were

discharged for disability. Omitting the number transferred, there was one death to every 3.9 cases, and one discharge to every 5.4 cases.

An examination of the comparative mortality of diarrhœa and dysentery in the above hospitals in the Atlantic region, during the whole term of their existence, does not show any such evident relationship between latitude and mortality as was indicated by the figures published in Circular No. 6 for the chronic cases during the second year of the war. There are several reasons for this circumstance. In the first place, the proportion of those who were discharged on surgeon's certificate of disability was very different in the different hospitals, and was, as a rule, determined by administrative considerations rather than by the gravity of the cases. Thus at Albany, New York, one case was discharged out of every 2.3; at the Foster hospital, North Carolina, only one out of every 28.6. Of course the more serious and obstinate chronic cases were generally those selected for discharge. Where such discharges were numerous, the proportionate mortality in the hospital would naturally be low; where similar cases were detained for treatment, the mortality would be high. The question of discharge did not depend merely upon the opinion or caprice of the surgeon in charge and his assistants. These were often supervised by inspectors, or by boards of medical officers, without whose approval no discharge could be granted. The action of such inspectors and boards depended upon administrative exigencies perhaps quite as often as upon the nature of the cases. Sometimes circumstances made it desirable to discharge every patient who might be expected to recover under the favorable influences of home. Sometimes military reasons made it seem imperative to retain in hospital every man whose recovery would have added a musket to the active armies.

Then, again, the transfers from hospital to hospital were of necessity chiefly determined by military reasons. Whenever the movement of a great army made it desirable to disembarrass it of the sick in the field hospitals, they were transferred to the nearest general hospitals; and when these became overcrowded, the patients thought best fitted to bear removal were transferred to hospitals at more remote points. Hence, as a rule, the very gravest cases remained at the hospitals nearest the active armies, and this is probably one important reason why the hospital at Fortress Monroe, which received so many cases directly from the army of the Potomac on the Peninsula, and the armies of the Potomac and of the James before Petersburg, gives so large a ratio. Still greater was the mortality at the Annapolis hospital, which, being conveniently situated on Chesapeake bay, not merely received large numbers of sick directly from the same army by steamboat, but was also the hospital selected for the treatment of the sick among the exchanged prisoners of war delivered to the United States authorities before Richmond. A large number of these men had long suffered with chronic diarrhœa or dysentery at Belle Isle and other Confederate prisons, were in the last stage of the disease when released, and died shortly after reaching Annapolis. For this reason the mortality at that place was greater than at the Fortress Monroe hospital, although the latter was nearer the base of operations.

The convenience of water transportation led also to the transfer of large numbers of sick by steamboat from the same army to such other hospitals as were readily accessible in this manner; for example, the Portsmouth Grove hospital, the hospitals in New York harbor, and the Baltimore hospitals; and, therefore, it is not surprising that the mortality in these hospitals was fully as great as it was in the Washington hospitals, which were

the base hospitals of the army of the Potomac during a large part of the war, and which continued to receive sick from that army by steamboat when it operated on the Peninsula and before Richmond.

The Philadelphia hospitals, on the other hand, received large numbers of patients by transfer from the hospitals of Fortress Monroe, Washington, and Baltimore, where they had been treated for a while, and where many of the worst cases were left, and chiefly from this reason, no doubt, the proportion of deaths among the diarrhœal cases in the Mower and Satterlee hospitals was about as small as it was in the inland New York and New England hospitals. In fact the investigation would seem to indicate that the more northern hospitals owed their comparatively small mortality as much to the fact that they received their patients by transfer from other hospitals, where a large part of the worst cases had been sifted out, as to their geographical position.

In the case of the hospitals south of Fortress Monroe, such as the Foster hospital and the Hilton Head hospital, the mortality was rendered much smaller than it would otherwise have been by the circumstance that obstinate chronic cases were very generally sent on hospital transports to the north, which, of course, not merely diminished the relative mortality in the hospitals of North and South Carolina, but increased that of those northern hospitals in New York harbor, Portsmouth Grove, and other points accessible by water, to which such patients were sent.

Similar transfers of vast numbers of patients from hospital to hospital occurred also in the Central region. Hospital steamboats were employed for the purpose on the Mississippi river and its tributaries, and the railroads were extensively used. Considerable numbers were also sent by sea from New Orleans to New York harbor and other northern points, and helped to swell the mortality of the hospitals there. Before the fall of Vicksburg this was the only way in which patients could be sent north from New Orleans.

Notwithstanding the interference of these transfers, it will be seen that, in the Central region, as a general rule, diarrhœal diseases were more fatal the more southern the situation of the hospital. The mortality from chronic diarrhœa and dysentery at the general hospital at Cairo, during the second year of the war, was stated in Circular No. 6 to have been greater than that at any other point in the Central region. This observation it will be seen does not hold good for the whole war, when the acute cases and deaths are also considered. It will be observed that the proportion of deaths at the Marine hospital, St. Louis, at Cairo, at Jeffersonville, and at the Brown hospital, Louisville, is very nearly the same; it is greater at the Cumberland hospital, Nashville, and still greater at the Gayoso hospital, Memphis, and the two New Orleans hospitals. The rate at Jefferson Barracks, St. Louis, is exceptionally large, if its geographical position alone is considered; that at Benton Barracks, St. Louis, and at Madison, Indiana, is exceptionally small.

In the Camp Dennison and Harvey hospitals the fatality of diarrhœal diseases was less than in any of the other hospitals in the Central region above mentioned. Both received their patients by transfer from the hospitals immediately upon the Ohio and Mississippi rivers. Steamboat transportation brought these latter into very similar relations with the great armies, which explains the fact that the fatality of the diarrhœal cases was about the same in most of them. The greater mortality in the Cumberland and Gayoso hospitals is partly explained by the fact that the Nashville and Memphis hospitals were so long the base hospitals of the western armies. One of the New Orleans

hospitals gives a greater, the other a less mortality than the Memphis hospital. Had the Mississippi river been open for the free transfer of the sick during the whole war, it is probable that in spite of the more southern situation of these hospitals they would, like the hospitals on the southern Atlantic coast, have had a smaller mortality than those situated nearer the chief arena of conflict.

It will be noticed that the difference in the proportion of patients discharged for disability in the different hospitals was as great in the Central as in the Atlantic region, amounting to one in 2.4 cases at Madison, Wisconsin, and only one in 86 at Jeffersonville, Indiana. At this latter hospital, however, the transfers to other hospitals were exceedingly numerous, amounting to about one-half of all the patients admitted with diarrhœa and dysentery.

The foregoing brief analysis of the records of a number of selected hospitals would seem to indicate that, even had it been possible to analyze all the hospital records in like manner, no very precise information as to the effect of latitude on the mortality from diarrhœa and dysentery could have been obtained from that source, the influence from this cause being masked by variations in the freedom with which discharges for disability were granted, by the frequent transfers from hospital to hospital, and by the neighborhood of individual hospitals to the seat of war. Moreover, these perturbing circumstances must have been still further complicated by strictly local conditions peculiar to each hospital; such as the nature of the hospital site, the character of the buildings, the amount of air-space afforded to each patient, and the general hygienic management of the establishment. It would be difficult to trace the influence of these conditions, unless the same class of patients had been received into every hospital; as it was, the causes determining the proportion of mortality in each case were too numerous for it to be possible to establish the exact part taken by each.

Something further may, it is true, be learned by comparing the annual ratio of cases in the several departments of each region. This has been done in the following tables for the Atlantic and Central regions, which have been compiled from the statistical tables of these departments in the First Medical Volume:

Tabular statement of the prevalence of diarrhœa and dysentery in the several Departments in the Atlantic region, expressed in ratio per 1,000 *of mean strength for each year.*

Department.	Year ending June 30, 1862.	Year ending June 30, 1863.	Year ending June 30, 1864.	Year ending June 30, 1865.
Department of the East	.....	296	359	338
Middle Department	445	437	351	614
Department of the Shenandoah	569	.....	.....	.....
Middle Military Division	.....	.....	.....	606
Department of Washington	.....	578	494	530
Army of the Potomac	640	995	558	708
Department of Virginia	451	748	802	903
Department of North Carolina	648	682	567	729
Department of the South	730	625	1,160	703

Tabular statement of the prevalence of diarrhœa and dysentery in the several Departments in the Central region, expressed in ratio per 1,000 *of mean strength for each year.*

Department.	Year ending June 30, 1862.	Year ending June 30, 1863.	Year ending June 30, 1864.	Year ending June 30, 1865.
Department of the Northwest	535	196	464	517
Northern Department	.....	569	550	538
Department of West Virginia	696	480	323	.....
Department of the Missouri	692	522	419	570
Department of the Ohio	.....	569	560	.....
Department of the Cumberland	1,084	1,017	627	.....
Department of the Tennessee	1,469	944	764	.....
Military Division of the Mississippi, Part 1	.....	.....	.....	747
Military Division of the Mississippi, Part 2	.....	.....	.....	620
Department of Arkansas	.....	.....	698	804
Department of the Gulf	1,637	1,473	963	872

In these tables it will be seen that the ratio of cases to strength is, as a rule, proportionately greater in the more southern departments. The exceptions are not numerous, and generally are the result of an increased number of cases in armies subjected to unusual privations or exposure by the exigencies of active campaigns. Similar ratios cannot be computed for the mortality of the several departments on account of the transfers of the patients in hospital from department to department; but as very generally, at least, an increased number of cases of diarrhœa and dysentery is accompanied by increased severity in the form of the disease prevailing, the tables have a certain value in indicating the influence of latitude, though it cannot be assumed that the mortality stands in any constant numerical relation to the number of cases.

Influence of Season.—The monthly ratios of cases to strength show that throughout the period represented by the tables, both among the white and the colored troops, and in the Pacific as well as in the Atlantic and Central regions, diarrhœa and dysentery were most frequent during the summer and autumn. Where marked deviations from this rule occur, they are generally explicable when the movements and operations of the great armies are taken into consideration.

The following tables give the monthly ratios of cases per 1,000 of mean strength among the white troops in each region. It must be borne in mind that the ratios are derived from the number taken on sick report monthly with diarrhœa and dysentery. They do not represent, therefore, the whole number sick with these diseases, but simply the new cases. The mean strengths used in computing the ratios include the troops in the field and in garrison in each region so far as they are represented in the reports. The sick in general hospitals are not included in the strength, because the cases among them are not represented in the reports.* The ratios for the year are not the sum of the monthly ratios, but are directly computed from the mean strength for the year and the total number of cases.

* The data from which these ratios are constructed will be found in the following tables: Atlantic region, Tables XII, XXXIII, LVI, LXXXII, XCVI; Central region, Tables XX, XLIII, LXVII, XCI, XCVII; Pacific region, Tables XXIII, XLVI, LXX, XCIV, XCVIII, Vol. I, Part I.

Number taken on sick report each month with diarrhœa and dysentery among white troops, expressed in ratio per 1,000 *of mean strength.*

The following tables give the monthly ratio of deaths per 1,000 of mean strength among the white troops in each region. In computing these tables the strength in general hospitals during each month has been added to the strength in the field and in garrison, because the deaths among both are represented by the reports.* The ratios, being small as compared with those which represent the cases, have been carried out to two decimal places; if the decimal point is disregarded, they may be read as whole numbers representing the ratio of deaths per hundred thousand of mean strength.

Monthly mortality from diarrhœa and dysentery among white troops, expressed in ratio per 1,000 of mean strength.

To facilitate the study of these ratios the diagrams facing page 22 have been constructed. The upper diagram represents the monthly ratio of cases, the lower one the monthly ratio of deaths, per 1,000 of strength. The death ratios being much smaller than the ratios for cases, the monthly fluctuations would not have been visible with sufficient distinctness had both diagrams been constructed on the same scale; in that which represents the deaths, therefore, the scale of the ordinates is fifty times greater than the scale used in that which represents the cases.

An examination of the upper diagram will show that in the Atlantic region the greatest monthly ratio of cases was in July, 1861, when it was 167 per 1,000 of mean strength, after which it progressively diminished until February, 1862, during which it was 22 per 1,000. The ratio then again increased, attaining its next maximum during July, 1862, when it was 128 per 1,000. This was the month following the disastrous

campaign of the army of the Potomac on the Peninsula. The ratio diminished to 88 in August, the army of the Potomac having been brought up to the neighborhood of Washington; it increased again in September, and attained 110 in October, the month following the battle of Antietam. After this it steadily diminished to 32 in April, 1863. The summer maximum in 1863 was attained in August, during which the ratio was 90; it was nearly as great during September, being 87; and then again diminished, falling gradually to 18 in February and March, 1864. The summer maximum of 1864 was attained in July, being 117; for August it was nearly as great, being 110. It then steadily diminished to 26 in February, 1865, and was again rising when the war came to an end and troops began to be mustered out. The summer maximum of 1865 occurred in June, and was only 66. The minimum reached in February, 1866, was 14; and the ratio had again risen to 48 in June, 1866, which is the last month represented in the tables.

In the Central region the greatest monthly ratio was 144 per 1,000 of strength, for August, 1861. The minimum during the winter of 1861–'62 was 55, reached in February. This was followed by a sudden increase to 111 in April, the month during which the greater portion of the Western armies lay at Pittsburg Landing. With their subsequent advance the number of new cases diminished to 67 in August; increased in September to 88; and fluctuated during the following winter, the ratios remaining higher than during any other winter in the Central region or any winter ratios in the other regions. The minimum during the winter was in December, 1862, and was 60 per 1,000. The fluctuations continued during the following spring and summer, rising at length to 88 in August, 1863; after which the rate steadily diminished to a minimum of 27 in February, 1864; and subsequently gradually increased to a maximum of 94 in the following June. It then diminished to a minimum of 34 in February, 1865; rose to its maximum during the summer of 1865 in June and July, being 64 for each month; fell off subsequently to 23 in March, 1866; and had again risen to 63 in June, when the table closes.

In the Pacific region the maxima were 38 for August, 1861; 40 for July and August, 1862; 29 for July, 1863; 32 for September, 1864; 29 for October, 1865; and 26 for May, 1866. The winter minima were 11 for January, 1862; 8 for February, 1863; 8 for February, 1864; 10 for December, 1864, and February and March, 1865; and 9 for February, 1866.

In the diagram representing the mortality attention is at once arrested by the very small mortality in the Pacific region throughout the whole period, and the comparatively small mortality in the other regions during the first year. It will be observed that subsequently, as a rule, the monthly mortality in the Atlantic and Central regions was greater during the latter part of the summer, fall, and early winter, than during the rest of the year. In the Atlantic region the ratio did not rise above one per 1,000 of strength until August, 1862. It continued above this figure during September, October, November, and December, the maximum being 1.30 per 1,000 in October. The ratio did not again reach one per 1,000 until October, 1863; the minimum during the intervening period being in May. It was 1.38 per 1,000 for October, and remained above one during November and December. After this it did not again attain one per 1,000 until July, 1864, the minimum meanwhile being again in May. During July the mortality was 1.52 per 1,000; in August it rose to 2.47; it continued at nearly this figure during September and October, fell off in November to 1.55, rose again in December to 2.43, and fell off in January, 1865,

3.80 3.60 3.40 3.20 3.00 2.80 2.60 2.40 2.20 2.00 1.80 1.60 1.40 1.20 1.00 .80 .60 .40 .20 .00

to 1.38. After this it did not diminish during the spring in as marked a manner as during previous years, but fluctuated, always remaining comparatively high, the minimum, again in May, being .88. During all the period from June to November, 1865, it remained above one per 1,000, the maximum being in July. After November, 1865, the curve rapidly descends to nothing in April and May, 1866, increasing again slightly in June.

In the Central region the ratio first exceeded one per 1,000 in May, 1862, and afterward steadily increased to 2.01 per 1,000 in October. It then fell off to 1.49 for December, increased to 2.49 in March, 1863, fell off again to 1.85 for May, and then rapidly rose to 3.49 for August. After this it gradually diminished to 1.34 for January, 1864, and in February fell below one per 1,000 for the first time since May, 1862. It did not again exceed one per 1,000 till June, 1864, the minimum being in April. For June it was 1.61; during July, August, September, and October it was 3, or nearly 3, per 1,000; and then it slowly fell off, remaining, however, above one per 1,000 till June, 1865, when it was .98. For July, 1865, it was more than 2 per 1,000; in August, nearly 2; during September and October, more than 2; during November and December it again diminished; fell below one per 1,000 in January, 1866; and then steadily diminished to .29 in April, after which it again slightly increased.

In the case of the colored troops the monthly ratios, computed in the same manner as those for the white troops which have just been discussed, show a similar prevalence of diarrhœa and dysentery during the summer and fall, with a corresponding diminution during the winter months. The monthly ratio of mortality is, however, much greater. These ratios are presented in the following tables:*

Number taken on sick report each month with diarrhœa and dysentery among colored troops, expressed in ratio per 1,000 *of mean strength.*

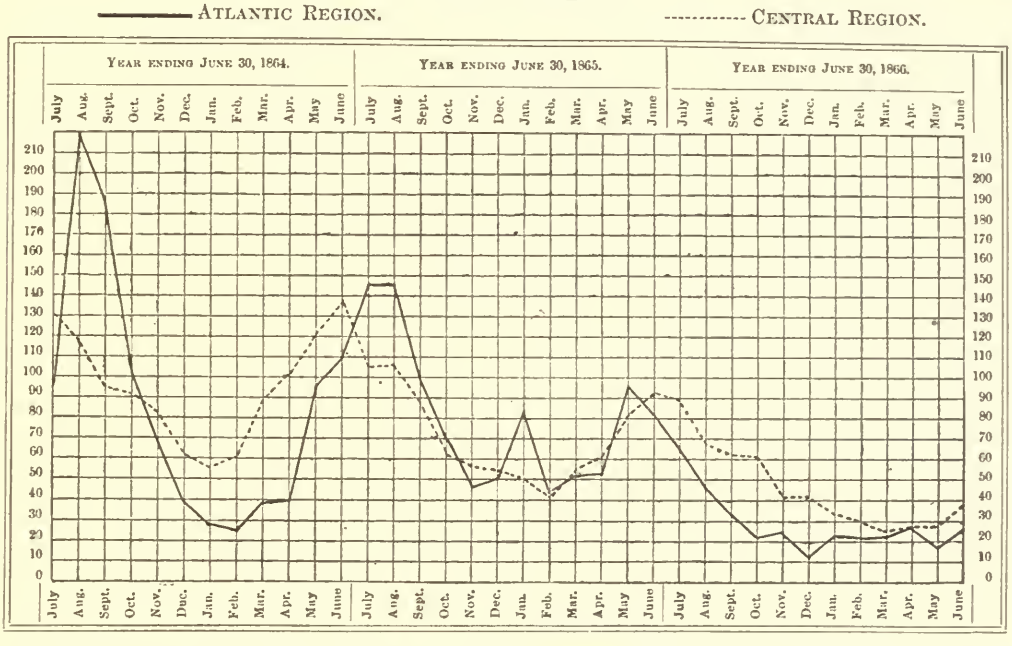
The ratios embraced in the foregoing tables are graphically represented in the accompanying diagrams, which have been constructed on precisely the same scale as those representing the cases and deaths among the white troops, the ordinates in the mortality diagram being on a scale fifty times greater than the scale used for the cases. The reasons for adopting a greater scale for the mortality (page 21) do not apply with so much force to the case of the colored troops, but it appeared desirable that the same scales should be used as for the whites.

Diagram showing the monthly ratio of the cases of diarrhœa and dysentery among colored troops.



ATLANTIC REGION.
CENTRAL REGION.
YEAR ENDING JUNE 30, 1864.
YEAR ENDING JUNE 30, 1865.
YEAR ENDING JUNE 30, 1866.
July Aug. Sept. Oct. Nov. Dec. Jan. Feb. Mar. Apr. May June
0 10 20 30 40 50 60 70 80 90 100 110 120 130 140 150 160 170 180 190 200 210

An examination of the diagram which represents the monthly ratio of cases shows that in the Atlantic region the greatest monthly ratio occurred in August, 1863, when it was 219 per 1,000 of strength. The ratio then diminished monthly to 25 per 1,000 in February, 1864, and subsequently increased in a fluctuating manner to 145 in July and August. It then again diminished during September and October, after which, with the exception of a temporary increase in January, 1865, it remained in the vicinity of 50 per 1,000 from November to April, 1865. In May it rose to 96 per 1,000, subsequently again diminishing gradually to a minimum of 13 per 1,000 in December, after which it again somewhat increased.

In the Central region the ratio was 131 per 1,000 in July, 1863, diminishing gradually to 56 in January, 1864, and again steadily increased to 137 in June, 1864; it then diminished steadily to 42 in February, 1865; rose to 93 the following June; fell gradually to 26 in March, 1866; continued at 27 during April and May, and rose to 37 in June.

The diagram opposite page 26 represents the mortality. It shows that in the Atlantic region the mortality rapidly rose from nothing in July, 1863, to 1.61 per 1,000 in September; after which it again diminished to nothing in February, 1864. It then rose in a fluctuating manner to an autumnal maximum of 3.58 for September and 3.30 for October, and again fell off, but with fluctuations, to 1.44 in April, 1865. This was followed

by a sudden rise to 3.22 in May, 3.63 in June, and 3.45 in July, followed by a sudden fall to 1.07 in August. Then came an autumnal rise to 2.20 in October, maintained at 2.06 for November. In December the ratio suddenly fell to .22 per 1,000, after which it fluctuated, always, however, remaining less than one per 1,000 till May, 1866, during which no deaths occurred. During June the ratio again increased to nearly one per 1,000.

In the Central region the mortality was conspicuously greater than in the Atlantic during the first year and a half. During August, 1863, the ratio reached 12.36 per 1,000. After this it diminished monthly to 2.32 in February, 1864, and then rose again to 6.28 in June, and remained above 6 during July, August, and September. After this it fell fluctuatingly to 1.73 in April, 1865, and then rose again to 3.30 in July. It remained above three per 1,000 during August, September, and October, after which it steadily diminished till the close of the period represented by the tables.

The ratios presented above appear to establish beyond all question the great influence of season on the prevalence of diarrhœa and dysentery. Cases occurred at all times of the year, indicating that season was only one of the causes at work; but the summer and autumn always brought with them a great increase in the number of cases, followed, as might be expected, by an increase of the mortality.

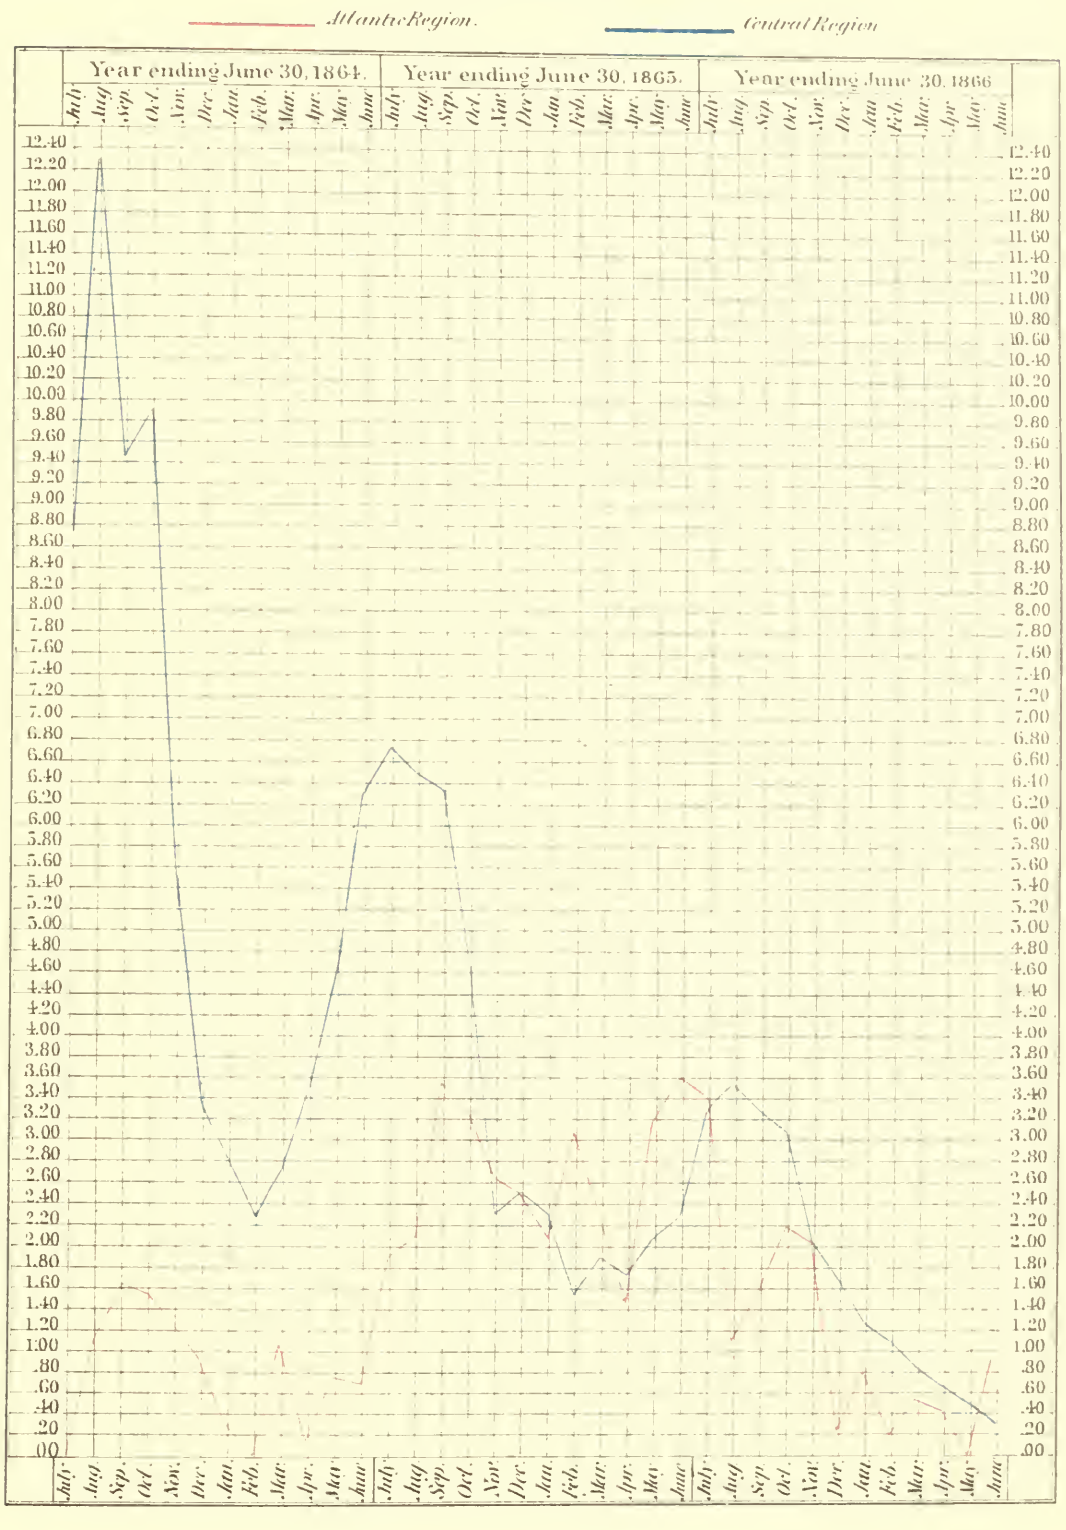
Diarrhœa and Dysentery in the Confederate Armies.—It is greatly to be regretted that it is not possible to ascertain with any accuracy the extent to which diarrhœa and dysentery prevailed in the Confederate armies, and the mortality which resulted. Whatever statistical or other reports may have been collected at the office of the Confederate Surgeon General were destroyed at the time of the fall of Richmond, along with other archives of the Confederate War Department, and the fragmentary information which it has been possible to collect from various sources is of the most unsatisfactory character.

In July, 1868, Dr. T. H. Williams, formerly a surgeon in the Confederate army, furnished to the Surgeon General's Office copies of his consolidated monthly reports of sick and wounded for the Confederate army of the Potomac from July, 1861, to March, 1862, during which time he was its medical director. These consolidated reports are imperfect in the matter of mortality, the total number of deaths being given in the general summary, but not the number of deaths from each disease. The deaths in general hospital are not included. No notion of the mortality from diarrhœa and dysentery can therefore be obtained from these reports. They give, however, the monthly number of cases, and although they do not embrace reports from all the regiments present, represent so considerable a strength that it is probable the ratios deduced give a just idea of the prevalence of the disorders in question in the army to which they refer.

A comparison of these reports with those of the Federal army of the Potomac for the same period shows that the ratio of cases to strength was considerably less in the latter army. The Confederate reports represent an average mean strength of 49,394. During the nine months 36,572 cases of diarrhœa and dysentery are reported, being 740 per 1,000 of mean strength. The reports of the Federal army of the Potomac for the same period represent an average mean strength of 111,168; the number of cases reported is 45,214, being 407 per 1,000 of mean strength for the nine months, or not much more than half the proportion of cases which occurred in the Confederate army.

The following table gives the mean strength represented by the reports, the number of cases, and ratio of cases to strength for each month:

Diagram showing the monthly ratio of deaths of Diarrhoea and Dysentery among Colored troops.



Number of cases of diarrhœa and dysentery in the Confederate and Federal drmies of the Potomac from July 1, 1861, *to March* 31, 1862, *with the ratio per* 1,000 *of mean strength for each month.*

Month.	Confederate Army of the Potomac.			Federal Army of the Potomac.		
	Mean strength represented by the reports.	Number of cases.	Ratio per 1,000 of mean strength.	Mean strength represented by the reports.	Number of cases.	Ratio per 1,000 of mean strength.
July, 1861	21,577	3,123	145	17,709	3,450	195
August, 1861	50,525	6,965	138	50,608	6,186	122
September, 1861	58,360	3,432	59	85,408	5,848	68
October, 1861	58,918	3,821	65	113,204	7,134	63
November, 1861	55,099	3,388	61	133,669	6,314	47
December, 1861	56,700	3,952	70	152,759	4,447	29
January, 1862	57,089	4,467	78	167,267	3,910	23
February, 1862	54,810	4,528	83	153,308	3,151	21
March, 1862	31,470	2,896	92	126,588	4,574	36

A comparison of the ratios for the two armies shows that in both the proportion taken sick was greatest during July and August, 1861, and that the ratio diminished during the winter, again increasing in March, 1862. But the winter ratios of the Confederate are much larger than those of the Federal army. During July and September the Confederate ratios are less than the Federal, but these months are the only exceptions.

Of 36,572 cases embraced in the reports of Dr. Williams, 25,971 are acute diarrhœa and 8,286 acute dysentery, making 34,257 acute cases. There are 1,874 cases reported as chronic diarrhœa and 441 as chronic dysentery, making 2,315 chronic cases, the proportion being one chronic case to fifteen acute. In the Federal army of the Potomac for the same period the proportion was one chronic case to eighteen acute.* From the greater proportion of chronic cases we may infer that the ratio of mortality was greater in the Confederate than in the Federal army at the time under consideration, although we have no means of determining precisely what the ratio was.

Dr. Williams has also furnished to the Surgeon General's Office consolidated monthly reports of sick and wounded for certain general hospitals in Virginia under his charge during the months of September, October, November, and December, 1862. The reports embrace the hospitals at Petersburg, Danville, Lynchburg, Farmville, Charlottesville, Staunton, Gordonsville, Culpepper Court-House, and Warrenton. In these, as in his reports for the army of the Potomac, the total number of deaths each month is given in a general summary, but they are not distributed among the several diseases, so that it is impossible to ascertain from them the mortality from diarrhœa and dysentery. The number admitted was as follows:

Acute diarrhœa	2,474	Chronic diarrhœa	2,113
Acute dysentery	381	Chronic dysentery	145
Total acute	2,855	Total chronic	2,258

* See Table VI, Part I, Vol. I.

The total number of sick admitted during the same period was 34,890, the proportion of diarrhœal diseases being rather more than one in seven.

Among the Confederate archives which fell into the hands of the United States authorities after the close of the war, is a full series of registers of the Chimborazo hospital, Richmond, Virginia, extending from October 17, 1861, to March, 31, 1865. As this hospital was situated immediately at the base of operations of one of the chief armies of the Confederacy, and received during the war nearly seventy-eight thousand sick and wounded soldiers, it was hoped that its records would prove extremely valuable. It is true that separate registers were kept in the different wards, and as patients were continually transferred from ward to ward the labor of preparing a correct statistical statement from them was very great. This difficulty, however, was overcome by tracing the transfers of each individual soldier before commencing to compile the statistics of the hospital, and hence does not interfere with the accuracy of the result. More unfortunate is the circumstance that the names of nearly nine thousand soldiers are recorded as admitted, without any record of what became of them. It appears from the registers that altogether 77,889 soldiers were admitted to this hospital, of whom 63,357 were sick, and 14,532 wounded. Of the sick, 3,146 died, 18,049 were transferred to other hospitals, and there is no record of what became of 7,348. Of the wounded, 798 died, 3,809 were transferred to other hospitals, and there is no record of what became of 1,534. Besides these omissions, due to negligence on the part of those who kept the registers, there is an unavoidable difficulty arising from an administrative reason. A very large number of the patients were sent home on furlough, who do not appear to have returned to this hospital, and whose fate cannot be ascertained. The whole number thus furloughed was 13,080, of whom 8,052 were sick, and 5,028 wounded. Many of these men merely went home to die.

The number of admissions for diarrhœa and dysentery recorded is 10,503, or one out of every 6 of the sick. Of these, 2,856 were transferred to other hospitals, 1,570 furloughed, and there is no record of what became of 1,408. Omitting these, 4,669 cases remain, the results of which are recorded. Out of these, 455 died, or one out of every 10, and 77 were discharged for disability, or one out of every 61.

The mortality as thus computed is nearly a third less than that of the Lincoln hospital at Washington, and almost one-half that of the Hampton hospital at Fortress Monroe.*

Some valuable, though fragmentary, information with regard to the health of the Confederate armies has been collected and published by Dr. Joseph Jones, formerly a surgeon in the Confederate service.† This gentleman had access at various times during the war to the records of the Confederate Surgeon General and other official sources of information, and appears to have used his opportunities, such as they were, with considerable diligence. According to Dr. Jones, the reports of sick and wounded for the

* The figures obtained by analyzing the registers of the Chimborazo hospital differ very much from those which have been published by Dr. Joseph Jones, (Richmond and Louisville Medical Journal, June, 1870, page 650,) not merely because Dr. Jones only includes a part of the time—(he does not state the precise limits, but gives the "Total number admitted, 47,176; deaths, 3,031,") but also because he computes his ratios of mortality upon the whole number of admissions, without regarding the transfers to other hospitals.

† "Observations upon the losses of the Confederate armies from battle, wounds, and disease, during the American Civil War of 1861-'65," &c., &c., by Joseph Jones, M. D., in the Richmond and Louisville Medical Journal, October, 1869, p. 339; November, 1869, p. 451; March, 1870, p. 257; and June, 1870, p. 635. See also his essay "On the prevalence and fatality of pneumonia and of typhoid fever in the Confederate army during the war of 1861-'65," and his "Investigations upon the diseases of the Federal prisoners confined in Camp Sumter, Andersonville, Georgia," which together constitute about one-third of the medical volume of the "Sanitary Memoirs of the War of the Rebellion, collected and published by the United States Sanitary Commission," New York, 1867. Dr. Jones has also announced a volume of "Medical and Surgical Memoirs" in preparation, (see Richmond and Louisville Medical Journal, May, 1871, p. 616,) which we are informed will contain an account of his observations in the Confederate army; but this has not yet been published. [Note. Vol. I of this work has appeared since the foregoing was prioted, New Orleans, 1876.—Ed.]

years 1861 and 1862, filed in the office of the Confederate Surgeon General, exclusive of those from the trans-Mississippi department, give the following figures for diarrhœa and dysentery:* "Field reports, 226,828 cases, and 1,696 deaths; hospitals, 86,506 cases, and 1,658 deaths." Dr. Jones points out† that the number of hospital admissions is so much greater than the number shown by the field reports to have been sent to hospital that the figures can be accounted for only by "the repeated transfers of patients during convalescence from one hospital to another." The relations of the hospital admissions to the number of cases on the field reports in the Confederate service were, in fact, identical with what has already been described‡ in the case of the field and hospital reports of the United States army, and in appreciating the figures of Dr. Jones we must, therefore, compare the number of cases on the field reports with the total number of deaths in the field and in hospital. This will give 3,354 deaths out of 226,828 cases, or one death to every 67.6 cases. The total number taken on sick report in the field during the same period, not counting the wounded, was 818,986; and the total number of deaths from disease reported in the field and in hospital was 31,338, or one death to 26 cases for all diseases. Hence the cases of diarrhœa and dysentery were to the whole number of cases as one to 3.6, the deaths to the whole number of deaths as one to 9.3.

Dr. Jones himself points out§ that the returns upon which the above statement is based are incomplete, and that the results are to be regarded as merely an approximate estimate; nevertheless, in the absence of more accurate information, they must be regarded as valuable.

If the ratios just given are contrasted with similar ones computed from the returns of the United States armies for the same period, it will be seen that the ratio of deaths to cases of all diseases is about half that reported by Dr. Jones for the Confederate armies; and hence that the ratio of death from diarrhœa and dysentery to all deaths from disease is very much smaller for the Confederate than it is for the United States armies. On the other hand, the ratio of the cases of diarrhœa and dysentery to the total number of cases of disease is about the same in both armies.

The consolidated tables for the United States armies from the commencement of the war to December 31, 1862,‖ give the total number taken on sick report for disease as 1,661,602, of which 482,764 were cases of diarrhœa and dysentery. The total number of deaths from disease reported in the field and in hospital was 33,090, of which 6,040 were deaths from diarrhœa and dysentery. These figures represent one death to every 50 cases for all diseases, and one death out of every 79.9 cases of diarrhœa and dysentery. The cases of diarrhœa and dysentery were to the whole number of cases as one to 3.4; the deaths to the whole number of deaths from disease as one to 5.5.

If from the whole number of cases and of deaths from disease the cases and deaths of diarrhœa and dysentery are deducted, it will be found that the ratio for all other diseases was one death to every 21 cases in the Confederate armies, one death to every 44 cases in the United States armies. It will be seen, therefore, that the small ratio of the deaths from diarrhœa and dysentery to all the deaths from disease in the Confederate armies resulted from the greater proportionate mortality of other diseases, and not from a smaller proportion of mortality from diarrhœa and dysentery.

---

† Loc. cit., p. 347.
‡ Introduction to Vol. I, Part I.
§ Loc. cit., p. 348.
‖ Vol. I, Part I, Tables III, XXIV, and XLVII.

It is greatly to be regretted that Dr. Jones, in presenting the results of his tabulation of the fragmentary Confederate returns for 1861–'62, does not state the mean strength represented by the reports. This would have greatly enhanced the value of his figures; as it is, no estimate of the ratio of cases or deaths to strength can be made for comparison with the ratios for the United States armies during the same period.

The papers of Dr. Jones, in the Richmond and Louisville Medical Journal, also contain several statistical tables drawn up from the reports and records of various Confederate general hospitals, which furnish fragmentary information on the subject of diarrhœa and dysentery. Thus the "tabular statement of the diseases treated in the general hospital of Charlottesville, Virginia,"* from July, 1861, to February, 1865, contains 2,172 admissions from diarrhœa and dysentery, and 81 deaths. The tabular statement for "the general hospitals in the army of the Potomac and Northern Virginia,"† from January, 1862, to March, 1863, contains 14,480 cases of diarrhœa and dysentery, and 587 deaths. The tabular statement for "the general hospitals in and around Richmond, Virginia,"‡ from September, 1862, to March, 1863, contains 8,737 cases of diarrhœa and dysentery, but the deaths are only reported for January, February, and March, 1863, during which period there were 1,603 cases and 74 deaths. The tabular statement for "the general hospitals in Virginia, including those in and around Richmond, Virginia,"§ for April, May, June, and July, 1863, contains 13,758 cases of diarrhœa and dysentery, but the number of deaths is not stated.

The value of all these statistical tables is greatly impaired by the fact that the number of cases of each disease transferred from hospital to hospital is not reported, and as there is no way of ascertaining the extent to which cases were duplicated in this way, the proportion of deaths to cases has not much significance.

In the report of his investigations upon the diseases of the Federal prisoners at Andersonville, Dr. Jones has given a very complete statement of the sickness and mortality among the Confederate troops detailed as the guard at that place during the months of July and August, 1864.‖ During the month of July there were 172 cases and 6 deaths of diarrhœa and dysentery out of a mean strength of 3,881 officers and men; during August, 351 cases and 9 deaths of diarrhœa and dysentery out of a mean strength of 3,629 officers and men. Dr. Jones gives separately the reports of the several regiments comprising the guard, and of the post hospital in which the more serious cases of disease occurring among them were treated.¶ In condensing the above statement from his tables the cases given represent only those on the regimental returns, but the deaths in the post hospital are included. The figures correspond to a ratio of 44 cases and 1.54 deaths per 1,000 of mean strength during the month of July, and 97 cases and 2.48 deaths per 1,000 of mean strength during the month of August.

The ratio of cases for both July and August are considerably less than the ratios given on page 19 for the white troops of the United States armies in the Atlantic region during the same months of 1864. The mortality rates of the white troops of the United States armies in the Atlantic region, from diarrhœa and dysentery during the same months,

* The Richmond and Louisville Medical Journal, March, 1870, p. 272.

† The same, June, 1870, p. 652. ‡ Loc. cit., p. 653. § Loc. cit., p. 654.

‖ Sanitary Memoirs of the War of the Rebellion, collected and published by the United States Sanitary Commission. Medical Volume, New York, 1867, p. 553.

¶ But adds the 61 cases sent to the post hospital to the number on the regimental reports, which already included them, or should have done so, making thus 584 cases instead of 523. Op. cit., p. 563.

given on page 21, are very nearly the same as those of the Andersonville guard, being 1.52 per 1,000 of strength for July, and 2.47 for August.

Upon the whole it must be conceded that the data above presented are not sufficiently complete to warrant the expression of an opinion as to whether the mortality from diarrhœa and dysentery in the Confederate armies throughout the war was greater or less than it has been shown to have been in the armies of the United States.

Dr. Jones has expressed the opinion, derived from his own extensive observations, that these diseases destroyed and disabled more soldiers in the Confederate armies than gunshot wounds. He says: "Chronic diarrhœa and dysentery were the most abundant and most difficult to cure amongst army diseases; and whilst the more fatal diseases, as typhoid fever, progressively diminished, chronic diarrhœa and dysentery progressively increased, and not only destroyed more soldiers than gunshot wounds, but more soldiers were permanently disabled and lost to the service from these diseases than from the disability following the accidents of battle."*

If the latter part of this paragraph does not, in the absence of exact statistical data, considerably exaggerate the mortality and disability produced by these diseases, it must be admitted either that they were much more fatal in proportion to mean strength, or that gunshot wounds were much less so, than in the armies of the United States. In view of the paucity of statistics, however, it would hardly be wise to regard the opinion of Dr. Jones as representing more than the general impression made upon his mind by the extreme prevalence and great fatality of the disorders in question.

Diarrhœa and Dysentery among the Prisoners of War held by the Confederates.—Before concluding these preliminary statistical remarks the subject of the prevalence of diarrhœa and dysentery among the prisoners of war on both sides requires consideration. It might be anticipated that the influences prevailing in the barracks and camps in which prisoners of war were confined would prove even more unfavorable than those of the camps and barracks of the active forces, and that intestinal fluxes would be both more common and more fatal, even if reasonable care should be taken to provide proper shelter and to furnish abundant supplies of suitable nutritious food. If these indispensable humanities were unavoidably or wilfully neglected, the result could readily have been foreseen.

Full statistical reports of what actually occurred on either side do not exist, but the records of sickness and mortality among the Confederate prisoners in the hands of the United States authorities are comparatively complete, while those referring to the Federal prisoners in the hands of the Confederates are exceedingly fragmentary. In the first instance, it has been possible to prepare an alphabetical register of deaths, embracing very nearly all which occurred, and which assigns the cause as reported by the attending surgeon in the great majority of instances. Monthly reports of sick and wounded from the larger prison depots are also on file, and separate reports of the prisoners of war treated in a number of the general hospitals. Altogether the reports must be considered quite as complete as those which represent the sickness and mortality of our own armies. In the case of the United States prisoners held by the Confederates, on the other hand, little statistical information can be obtained for any of the large depots except Andersonville and Danville, beyond the number of graves found after the close of the war. The general

* Op. cit., p. 638.

subject of sickness and mortality among prisoners of war, and the causes by which they were determined, must be reserved for a future chapter; in this place attention is directed only to the comparative prevalence and mortality of diarrhœa and dysentery. So far as can be ascertained, the mortality from these diseases among the prisoners held by the Confederates amounted to more than one-half of all the deaths from disease.

The original hospital register of the famous prison at Andersonville has fortunately been preserved, and is now deposited in the office of the Adjutant General. This book records 17,875 admissions of prisoners to hospital between February 24, 1864, and April 17, 1865. Out of this number 12,541 deaths are recorded. The causes of 1,292 deaths are not given; 163 died of wounds, and 11,086 of disease. There were 7,352 cases and 5,605 deaths of diarrhœa and dysentery recorded, the deaths amounting to a little over 76 per cent. of the cases, and to more than one-half of all the deaths from disease. A large number of the cases and deaths are entered on the register simply as diarrhœa or dysentery, without specifying whether the disease was acute or chronic, as shown in the following synopsis:

Cases and deaths from diarrhœa and dysentery recorded in the Andersonville Prison hospital register from February 24, 1864, *to April* 17, 1865.

	Admissions.	Deaths.
Acute Diarrhœa	1,286	956
Chronic Diarrhœa	1,331	831
Diarrhœa	2,812	2,224
Acute Dysentery	633	560
Chronic Dysentery	228	212
Dysentery	1,062	822
Total	7,352	5,605

Among the more fatal other diseases there are recorded 5,662 cases and 3,614 deaths from scurvy; 333 cases and 192 deaths from debility; 453 cases and 351 deaths from anasarca; 538 cases and 404 deaths from typhoid and malarial fevers; 99 cases and 60 deaths from gangrene; and 276 cases and 218 deaths from pneumonia. It will be observed that the deaths ascribed on the register to diarrhœa, dysentery, and scurvy constitute very nearly three-fourths of the deaths from all causes.

The above statement is derived from a careful count of each name entered on the hospital register. The register itself is well kept, in one very large folio volume of a characteristic blue-ruled yellow-tinted paper, extensively used in the Confederate States during the war. The writing is legible, and the manner in which the book is kept is every way creditable to the surgeons in charge of the hospital. It is not probable that it contains all the deaths which occurred, for there are 1,001 admissions recorded opposite which there is no entry to show what became of the patients. Moreover, it appears from a report of the Quartermaster General* that the graves of 13,705 Federal prisoners, 13,008

* See the "Report on the Treatment of Prisoners of War by the Rebel Authorities during the War of the Rebellion," by the committee of the House of Representatives, of which the Hon. John P. Shanks, of Indiana, was chairman.—Report No. 45, House of Representatives, 3d Session, 40th Congress. Government Printing Office, Washington, 1869, page 776.

of which it was possible to identify, were found at Andersonville after the close of the war. The discrepancy is no doubt partly due to the omissions to record the disposition of so large a number as 1,001 admissions, and perhaps, also, occasionally deaths occurred in the stockade which were not duly taken up on the hospital register, though as a rule it would appear that such deaths were taken up and recorded. On the whole, the medical authorities seem to have taken unusual pains to record faithfully the admissions and deaths as they actually occurred, and preference is, therefore, here given to this register over all other sources of information with regard to the sickness and mortality at this depot.*

Dr. Joseph Jones, in his elaborate report on the sanitary condition of the prisoners at this depot, presents in tabular form† a monthly statement of the number of cases and deaths among the Federal prisoners at Andersonville for six months, from March to August, 1864, inclusive. These tables, which possess a certain degree of value, were drawn up from the monthly reports of sick and wounded on file in the office of the surgeon of the post when it was visited by Dr. Jones in September, 1864.

During this period the mean number of prisoners present was as follows: March, 7,500; April, 10,000; May, 15,000; June, 22,291; July, 29,030; August, 32,899; the average strength for the whole period being 19,453. "During the six months, 12,090 cases and 3,530 deaths from acute and chronic diarrhœa, and 4,682 cases and 999 deaths from acute and chronic dysentery, were recorded. The cases of diarrhœa and dysentery together numbered 16,772, or nearly one-half of the total number of sick and wounded. The deaths caused by these two diseases are recorded at 4,529, or, in other words, these diseases caused more than one-half, or more exactly 58.7 per cent., of all the deaths. These figures are below the truth. As far as my personal examinations extended, almost every prisoner was affected with either diarrhœa or dysentery."‡

These figures represent an annual mortality from diarrhœa and dysentery alone of 466 per 1,000 of mean strength. The total mortality among the prisoners during the same period, as given in the tables of Dr. Jones, was 7,712; of these 27 were violent deaths, and 7,685 deaths from disease. This is at the rate of 790 deaths from disease per 1,000 of mean strength annually. The monthly sick reports used by Dr. Jones were evidently not drawn up merely from the hospital register mentioned above, for his tables contain 42,686 cases, while the number of admissions on the register during the same period was only 10,453. There is, however, but a trifling difference between the total number of deaths as given in the tables of Dr. Jones and the number recorded on the hospital register for the same period. It would hence appear probable that the sick reports contained non-fatal cases treated in the stockade as well as the fatal cases and those sent to hospital, while the non-fatal cases treated in the stockade are apparently not entered in the hospital register.

This circumstance would give very great value to the tables of Dr. Jones if they could be regarded as strictly accurate. There is reason to believe, however, that the clerks who prepared the reports occasionally modified the facts to make them conform to the printed

* A list of the deaths of Federal prisoners at Andersonville, purporting to extend from February 27, 1864, to February 2, 1865, was secretly copied by Private Dorcace Atwater, Co. D, Second New York Cavalry, a prisoner employed as a clerk in the prisoners' hospital, and was purchased from him by the Adjutant General. This list, which is quoted in the Report of the Congressional Committee on the Treatment of Prisoners of War, contained 12,631 deaths, being 90 more than the number given above, although the time represented is a month and a half less; in view of the excellent character of the original hospital register, it has not been thought desirable to do more than mention it in this place.

† Sanitary Memoirs, &c., collected and published by the United States Sanitary Commission. Medical Volume, New York, 1867, page 524.

‡ Op. cit., page 627.

blank employed. Thus the tables neatly distribute the deaths from diarrhœa and dysentery as follows:

Acute Diarrhœa	2,161
Chronic Diarrhœa	1,369
Acute Dysentery	848
Chronic Dysentery	151
Total	4,529

Whereas on the hospital register during the same period there are 1,381 deaths simply ascribed to diarrhœa, and 612 to dysentery, without specifying whether the disease was acute or chronic. Various other discrepancies are also to be observed between the number of deaths from particular diseases as counted on the hospital register and that given in the tables, which can therefore only be regarded as approximative.

There is no reason to believe that Dr. Jones had the slightest intention to misrepresent the facts. On the contrary, he appears to have been actuated by the most sincere desire to present the whole truth with the utmost fidelity. It was of course not in his power during his short visit to verify the sick reports by an actual count of the registers, and he probably did not suspect their accuracy. Moreover, the errors are not such as would have been intentionally made, and while the number of deaths from some diseases, as given by the sick reports, is smaller than the number on the hospital register, that from other diseases is larger, and the total mortality closely approximates the truth.

This is not the place for the full discussion of the causes which produced the fearful mortality among the Andersonville prisoners. The subject has been elaborately treated by Dr. Jones, and by a committee of the House of Representatives.* To these treatises the reader is referred for details, a simple outline of the leading facts being all that is here required.

Camp Sumter, as the depot was designated by the Confederate authorities, was situated about half a mile from Andersonville station, on the Southwestern railroad leading from Macon to Americus, Georgia. Originally about seventeen acres of ground were inclosed by a stockade of pine logs twenty feet high. The first prisoners arrived in February, 1864; by April there were 10,000. In July, the number of prisoners being above 29,000, and more being expected, the stockade was enlarged to an area of twenty-three acres and a half.† Through this inclosure flowed a sluggish stream of water about six feet in width, bordered on each side by a low swamp which occupied six acres of the narrow territory allotted to the prisoners. Into this stream and swamp the drainage of the camp took place, and the stream was at the same time the chief source of water supply. No shelter was provided by the Confederate authorities except for the hospital, but some of the prisoners contrived to build huts of pine boughs roofed with pieces of shelter tents, while others burrowed in the ground. There is conclusive testimony that the rations furnished were of poor quality and insufficient in quantity. Unbolted corn meal was chiefly used instead of flour, and the fragments of husk which it contained seemed to aggravate the tendency to diarrhœa and dysentery. A scorbutic condition of the system was consequently almost universal. The hospital accommodations were most meagre and inadequate.

* Report cited on page 33—note.

† According to Dr. Jones to twenty-seven acres. Page 501 of the Memoirs cited on page 33—note

At first a corner of the stockade was set aside for the purpose. In the latter part of May the hospital was removed to a point outside of the southwest angle of the prison inclosure. Here, in a space of about five acres, nearly two thousand sick were scantily sheltered by old and ragged tents. The number of bunks was insufficient, and many of the patients lay on the ground without even a blanket. The mortality which prevailed was the inevitable result of over-crowding, exposure, and starvation.

The condition of the Federal prisoners at Salisbury, North Carolina, appears to have been quite as bad as at Andersonville, if not worse; but no such careful records as were kept by the medical officer at Andersonville have been discovered, if indeed they ever existed. According to the report of the Quartermaster General the graves of 12,112 Union prisoners were found there after the close of the war; of these only 78 were so marked as to be identified.* At this place a brick factory, with the buildings used as boarding houses for the operatives, was originally used to shelter the prisoners, and about five acres of ground around them was inclosed by a high board fence. In the fall of 1864, 10,000 prisoners were sent there, and the buildings being quite insufficient the greater portion of them were without shelter. Exact accounts of the number of prisoners confined here, and of the diseases which produced the mortality, cannot be obtained, but it is stated by Assistant Adjutant General T. W. Hall, in a report to the Confederate Adjutant General, February, 1865,† that pneumonia and diseases of the bowels were the prevailing diseases.

Another large depot was at Danville, Virginia. Here some old tobacco warehouses served to shelter a portion of the prisoners. An exact account of the number confined cannot be obtained, but the greater portion of the seriously sick appear to have been treated in Division No. 2 of the Danville hospital. The register of this hospital has been secured, and is preserved in the office of the Adjutant General of the Army. It extends from November 23, 1863, to March 27, 1865. During this period 4,332 admissions were recorded, of whom 262 were transferred to other hospitals, and 1,084 died. The Quartermaster General reports that after the close of the war 1,323 graves of Union prisoners were found at this place, all of which it was possible to identify,‡ so that the records of Hospital No. 2 contain rather more than four-fifths of all the deaths. The number is so large as to be valuable for comparison with the Andersonville records. Of the 1,084 deaths recorded, 1,074 were from disease. The number of deaths from diarrhœa and dysentery was 592, being more than half of all the deaths from disease. These are distributed as follows: Diarrhœa 18, acute diarrhœa 50, chronic diarrhœa 507, dysentery 2, acute dysentery 6, chronic dysentery 5, colitis 4. During the same period the total number of admissions for diarrhœa and dysentery was 1,433, of whom 39 were transferred to other hospitals; omitting these, there was one death out of every 2.4 admissions. These figures represent a condition of things not unlike Andersonville, though on a smaller scale.

There is also preserved in the office of the Adjutant General of the Army a list of the deaths of Union prisoners in the prison at Cahawba, Alabama, copied from the original records kept by the medical officer in charge, Surgeon L. E. Profilet, of the Confederate army. This list contains 142 deaths, of which 135 were from disease; of these, 42 were from diarrhœa and 3 from dysentery. The register extends from December 28, 1863, to April 28, 1865. The actual number of prisoners present during this period is unknown. According to the report of Assistant Adjutant General D. T. Chandler,§ there were 2,151

* Page 776 of the Report cited on page 32—note.
‡ Page 773 of the same Report.
† Page 179 of the same Report.
§ Page 200 of the same Report.

prisoners there October 16, 1864, but how long anything like this number were present does not appear. The number of graves reported by the Quartermaster General as having been found at this place after the war was 147, all identified;* of these, 5 were citizens and 142 enlisted men, so that the list of Surgeon Profilet appears to be complete.

The Andersonville and Danville prisons are the only ones in which large numbers of Federal prisoners were confined for which it is at present possible to obtain even approximate statistical information with regard to the distribution of the deaths among particular diseases. The Quartermaster General reports† that, after the close of the war, 3,450 graves of prisoners were found at Richmond, Virginia, including the victims of the Libby, Smith, Pemberton, Castle Thunder, and Belle Isle prisons. At Florence, South Carolina, 2,795 were found; at Millen, Georgia, 748; and smaller numbers at other places. Such hospital records as may have been kept at these places have either been destroyed or concealed.

DIARRHŒA AND DYSENTERY AMONG THE PRISONERS OF WAR HELD BY THE UNITED STATES.—In the case of the Confederate prisoners in the custody of the United States authorities, diarrhœa and dysentery were far less fatal than among the Federal prisoners in the hands of the Confederates. The ratio of mortality was, nevertheless, large.

The alphabetical registers of the Surgeon General's Office record the deaths of 30,716 Confederate prisoners of war. This list embraces not merely the deaths in the great prison depots, but also those occurring in the several general and post hospitals and elsewhere, so far as it has been possible to collect them. From the character of the records, it is not possible that any considerable number have escaped notice. Of the whole number of deaths 5,569 were due to wounds, accidents, and injuries; the cause of death is not stated in 1,556 instances; while 23,591 deaths were due to disease. Of these, 7,281 were from diarrhœa and dysentery, viz: acute diarrhœa, 553; chronic diarrhœa, 5,501; acute dysentery, 676; chronic dysentery, 551. If we also include 113 deaths reported from inflammation of the bowels, we shall have a total of 7,394 deaths, or about one-third of all the deaths from disease.

The number of Confederate prisoners of war is approximately known, but the average duration of their captivity cannot be ascertained with sufficient accuracy to serve for the computation of the ratio of deaths to strength from the above figures. Fortunately, however, the monthly reports of sick and wounded from the principal prison depots furnish data for computing the ratios with regard to so large a portion of the whole number as to indicate very fairly the actual facts of the case. These monthly reports, made under the supervision of the surgeons in charge, give the mean number of prisoners present during each month, together with the number taken sick, and the deaths for each disease, the form being the same as that used for the monthly reports of sick and wounded in the general hospitals. From these the following statements have been compiled:

The monthly sick reports for the depot of prisoners at Camp Douglas, near Chicago, Illinois, represent a period of three years and five months, from February, 1862, to June, 1865, inclusive. The mean number of prisoners was 5,361, the greatest mean number for any one month being 11,700 for January, 1865. During the forty-one months 13,455 cases of diarrhœa and dysentery and 698 deaths were reported, being at the rate of 735 cases and 38.11 deaths per 1,000 of mean strength annually.

* Page 776 of the Report cited on page 32—note. † Loc. cit.

The monthly sick reports for the depot of prisoners at Alton, Illinois, represent a period of two years and ten months, from September, 1862, to June, 1865, inclusive. The mean number of prisoners was 1,008, the greatest mean number for any one month being 1,721 for January, 1865. During the thirty-four months 5,580 cases of diarrhœa and dysentery and 229 deaths were reported, being at the rate of 1,954 cases and 80.18 deaths per 1,000 of mean strength annually.

The monthly sick reports from the depot of prisoners at Johnson's Island, near Sandusky, Ohio, represent a period of two years and one month, from June, 1863, to June, 1865, inclusive. During this time the mean number of prisoners was 2,114; the greatest mean number for any one month was 3,204 for December, 1864. During the twenty-five months there were 1,855 cases of diarrhœa and dysentery and 46 deaths, being at the rate of 421 cases and 10.44 deaths per 1,000 of mean strength annually.

The monthly sick reports for the depot of prisoners at Camp Morton, near Indianapolis, Indiana, represent a period of two years and one month, from June, 1863, to June, 1865, inclusive. The mean number of prisoners was 2,865; the greatest number for any one month was 4,836 for August, 1864. During the twenty-five months 2,241 cases of diarrhœa and dysentery and 315 deaths were reported, being at the rate of 375 cases and 52.77 deaths per 1,000 of mean strength annually.

The monthly reports of sick and wounded for the depot of prisoners at Camp Chase, near Columbus, Ohio, commence May 20, 1863, when 500 prisoners were reported at the post. There were at that time a large number of paroled United States soldiers at Camp Chase, and the sick reports include the sick among them and the guard, as well as among the prisoners. After the first of February, 1861, separate sick reports were made for the prisoners. Prior to that time there is no means of ascertaining the number of cases among them; but the deaths were recorded by name, and were 131 in number. Of these, 4 died of wounds, 38 of diarrhœa and dysentery, 25 of typhoid fever, and 19 of pneumonia. The separate reports extend from February, 1864, to June, 1865, inclusive, a period of seventeen months. The mean number of prisoners present was 3,570; the greatest mean number for any one month was 7,760, during February, 1865. During the period of seventeen months covered by the reports there were 4,063 cases of diarrhœa and dysentery and 226 deaths, being at the rate of 803 cases and 44.69 deaths per 1,000 of mean strength annually.

The monthly sick reports for the depot of prisoners at Rock Island, Illinois, represent a period of one year and five months, from February, 1864, to June, 1865, inclusive. The mean number of prisoners was 6,030; the greatest mean number for any one month was 8,361 for July, 1864. During the seventeen months 3,874 cases of diarrhœa and dysentery and 363 deaths were reported, being at the rate of 453 cases and 42.49 deaths per 1,000 of mean strength annually.

The monthly sick reports for the depot of prisoners at Elmira, New York, represent a period of one year, from July, 1864, to June, 1865, inclusive. The mean number of prisoners was 6,591; the greatest mean number for any one month being 9,300 for September, 1864. During the year 4,379 cases of diarrhœa and dysentery and 1,394 deaths were reported, being at the rate of 664 cases and 211.50 deaths per 1,000 of mean strength annually.

The monthly reports of sick and wounded for the depot of prisoners at Fort Delaware,

Delaware, represent a period of one year and eleven months, from August, 1863, to June, 1865, inclusive. The mean number of prisoners was 6,406; the greatest mean number for any one month being 9,174 for June, 1864. During the twenty-three months 9,659 cases of diarrhœa and dysentery and 644 deaths were reported, being at the rate of 787 cases and 52.45 deaths per 1,000 of mean strength annually.

The monthly reports of sick and wounded for the depot of prisoners at Point Lookout, Maryland, represent a period of one year and ten months, from September, 1863, to June, 1865, inclusive. The mean number of prisoners was 9,610; the greatest mean number for any one month being 19,748 for May, 1865. During the twenty-two months 20,474 cases of diarrhœa and dysentery and 2,050 deaths were recorded, being at the rate of 1,162 cases and 116.36 deaths per 1,000 of mean strength annually.

The following table presents a synoptical view of the number of cases of acute and chronic diarrhœa and dysentery at these principal depots, compiled from the monthly sick reports of each:

Number of cases and deaths from diarrhœa and dysentery among Confederate prisoners of war at the chief prison depots, with the annual ratio per 1,000 *of mean strength.*

Prison Depot at—	Mean No. of prison'rs present.	Total Number of Cases and Deaths Reported.										Annual ratio per 1,000 of strength.	
		Acute Diarrhœa.		Chronic Diarrhœa.		Acute Dysentery.		Chronic Dysentery.		Total.			
		Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.
Camp Douglas, Ill., from Feb., 1862, to June, 1865...	5,361	7,351	165	3,023	393	2,815	132	266	8	13,455	698	735	38.11

Camp Morton, Indiana, from June, 1863, to June, 1865..	2,865	1,014	20	437	231	760	51	30	13	2,241	315	375	52.77
Camp Chase, Ohio, from Feb., 1864, to June, 1865...	3,570	2,691	24	1,103	191	187	9	82	2	4,063	226	803	44.69
Rock Island, Ill., from Feb., 1864, to June, 1865.....	6,030	1,095	17	697	278	2,016	51	66	17	3,874	363	453	42.49
Elmira, New York, from July, 1864, to June, 1865 ..	6,591	421	6	3,866	1,376	56	7	36	5	4,379	1,394	664	211.50
Fort Delaware, Del., from Aug., 1863, to June, 1865..	6,406	6,421	86	1,747	442	1,220	64	271	52	9,659	644	787	52.45
Point Lookout, Md., from Sept., 1863, to June, 1865..	9,610	13,555	286	2,414	1,282	3,722	247	783	235	20,474	2,050	1,162	116.36

It will be observed that this table includes 5,965 deaths from diarrhœa and dysentery, or about 82 per cent. of all the deaths from these diseases which occurred among the prisoners of war in the hands of the United States authorities; it must therefore be regarded as fairly representing their prevalence and mortality among the Confederate prisoners. At five of the nine stations the mortality ranged between 38.11 and 52.77 per 1,000 of mean strength annually, or rather more than twice the ratio of mortality from these diseases among the white troops of the United States armies during the last year of the war, and less than the mortality of the colored troops in the Central region during the year ending June 30, 1864. At one of the depots, Johnson's Island, where the prisoners were chiefly officers, it was very much less than this, being only 10.44 per 1,000. At three, Alton, Point Lookout, and Elmira, it was greater, being 80.18 for the first, 116.36 for the second, and 211.50 for the third of these stations.

It will be shown in a future chapter on the general subject of the sickness and mortality among prisoners of war that the treatment of prisoners by the United States author-

ities was very different from that which prisoners in the hands of the Confederates received. As a general rule they were housed in wooden barracks provided with ridge ventilation, and quite as good as those used for the United States troops in permanent camps. Where barracks or buildings were not provided, serviceable tents were supplied. The ration was quite liberal, and the difference in money value between the ration actually issued and that allowed to United States soldiers was credited to the prison fund, on which the surgeon in charge was authorized to draw for the purchase of vegetables and anti-scorbutics for the use of the sick. An examination of the detailed reports of the medical inspectors who visited the depots from time to time shows, however, that they were often unduly crowded; and the influence of this cause was exaggerated at Elmira by the existence in the camp grounds of a stagnant pond, into which the drainage of the camp flowed for six months of the year represented by the reports, and at Point Lookout by the malarial influences of the low tongue of land between the Potomac river and Chesapeake bay on which the depot was situated. The details with regard to each station will be presented hereafter.

Besides the reports from these principal depots there are sick reports on file for a number of minor stations, and separate reports for the scattered Confederate prisoners in some of the general hospitals.

Several thousand prisoners were sent to Hart's Island, New York harbor, in the spring of 1865, and released a few months after, the war having come to a close. Monthly sick reports for April, May, and June, 1865, are on file. The mean number of prisoners was 3,031, among whom 448 cases of diarrhœa and dysentery and 89 deaths were reported.

Reports are also on file for five months, from December, 1864, to April, 1865, from a prison depot established on Ship Island, Mississippi. The mean number present in December was 1,127, which had increased to 4,500 by April. The average number present during the whole period was 1,462, among whom 401 cases of diarrhœa and dysentery and 59 deaths were reported.

Besides these, reports are on file from the Prison hospital, (Hospital No. 2,) Louisville, Kentucky; the Gratiot street prison, St. Louis, Missouri; the prison at Little Rock, Arkansas; the Irving military prison, Memphis, Tennessee; and Fort McHenry, Maryland.

The report of the Prison hospital, Louisville, Kentucky, extends from April, 1863, to June, 1865, inclusive, with the exception of January and February, 1865, for which no reports were received. The average number of prisoners present during this period was 133. During the two years and one month the total number of cases of diarrhœa and dysentery reported was 158, of whom 7 died.

The reports of the Gratiot street prison, St. Louis, Missouri, extend from December, 1863, to May, 1865, inclusive. The average number of prisoners present was 248. During the year and a half 803 cases of diarrhœa and dysentery and 83 deaths were reported.

The reports of the prison at Little Rock, Arkansas, extend from February, 1864, to June, 1865, inclusive. The average number of prisoners present was 258. During the seventeen months 259 cases of diarrhœa and dysentery and 44 deaths were reported.

The reports of the Irving military prison, Memphis, Tennessee, extend from May, 1864, to March, 1865, inclusive. The average number of prisoners present was 48. During the eleven months 50 cases of diarrhœa and dysentery and 1 death were reported.

The reports of the prisoners confined at Fort McHenry, Maryland, extend from March, 1864, to June, 1865, inclusive. The average number of prisoners present was 186. During the sixteen months 28 cases of diarrhœa and dysentery and 6 deaths were reported.

Finally, during the course of the war a number of sick prisoners were carried from time to time to the general hospitals, where they were treated side by side with the sick United States soldiers. Separate reports of such cases were ordered to be made, but the order was not universally obeyed. Such reports are on file for various periods from the De Camp hospital, David's Island, New York harbor; the Foster hospital, Newbern, North Carolina; Hospital No. 1, Nashville, Tennessee; and the St. Louis and Barracks hospitals, New Orleans, Louisiana. These reports contain 781 cases of diarrhœa and dysentery and 239 deaths. The total number of deaths from diarrhœa and dysentery reported from these hospitals and minor stations is 528; making in all 6,493 deaths from these diseases on the monthly reports. The remaining 788 deaths contained in the alphabetical registers were reported by name from various quarters, chiefly from general and post hospitals, but simply in the form of lists of deaths, and no data exist by which the number of prisoners among whom they occurred can be ascertained.

In the foregoing section some of the more important statistical facts with regard to the prevalence of diarrhœa and dysentery during the war of the rebellion have been discussed. The reader is referred to the First Medical Volume for further details. Enough has been said to indicate the importance of a thorough study of these affections; but it may be mentioned further, as will be more fully shown in a subsequent portion of this chapter, that our experience during the war of the rebellion was very similar in this respect to what has been recorded of other armies in time of war, and particularly to what has invariably occurred during former wars in North America. Should the United States ever again put an army into the field there is every reason to believe that it will again suffer in the same way, unless, learning wisdom from experience, the military authorities take timely and efficient precautions to avert the evil. It has therefore seemed highly desirable to place upon record all that could be gleaned from the reports and other official documents in illustration of the causes, nature, and treatment of diarrhœa and dysentery, and this will be done at length in the next two sections.

The second section will contain reports and extracts from reports by medical officers relating to these diseases, and the third section such cases and autopsies as have been collected from the monthly reports, medical descriptive lists, and case-books of the general hospitals. In presenting this evidence the editor will as a rule refrain from comments, reserving any discussion of the pathology and treatment of these diseases for the fourth section, which will conclude the chapter.

Section II.

REPORTS AND EXTRACTS FROM REPORTS RELATING TO DIARRHŒA AND DYSENTERY.

A small number of special reports on diarrhœa and dysentery, as observed during the war, were made by medical officers, chiefly by those on duty in the general hospitals. These are presented in the following section. The sanitary reports made by the medical officers in charge of regiments, posts, and detachments also occasionally contained information on the subject. These reports were required by the regulations in force at the commencement of the war to be made quarterly. They were furnished, however, by so few of the regimental surgeons that, when the quarterly reports of sick and wounded in use before the war were replaced by the new form of monthly reports prepared by a board of medical officers in July, 1862, the separate sanitary reports were dispensed with, and instead an ample space, equal to about two pages of foolscap, for "remarks," was provided on the blanks issued for the monthly reports. This space was headed with minute "directions" as to the character of the information desired by the Surgeon General's Office. In these directions brief information was especially asked on each of the following heads, to be furnished whenever the diseases mentioned were prevalent: "*Fevers*—Their character and symptoms; an outline of the plans of treatment found most efficient, with remarks on the location and sanitary condition of camps or quarters during the prevalence of these disorders. *Diarrhœa and Dysentery*—Grade and treatment, with remarks on the character of the ration and the modes of cooking. *Scorbutic Diseases*—Character and symptoms, with observations on causation, and a statement of the means employed to procure exemption. *Respiratory Diseases*—Symptoms, severity, and treatment, with remarks on the sheltering of the troops and the atmospheric conditions. Similar remarks on other preventable diseases. Important cases of every kind should be reported in full. Where *post mortem* examinations have been made, accounts of the pathological results should be carefully prepared." The results of this plan of collecting information were not so satisfactory as was anticipated, nevertheless a number of cases and autopsies, and occasionally judicious descriptive remarks, were entered in this portion of the sick reports, and will be made use of in this and subsequent chapters.

A special effort was also made by several of the medical inspectors to collect the medical histories of the regiments in the departments to which they were attached. This was done especially by Medical Inspector E. P. Vollum, U.S.A., in the army of the Potomac in the latter part of 1862; by Medical Inspector W. H. Mussey, U. S. A., in North Carolina during the early part of 1863; and by Medical Inspector G. W. Stipp, U. S. A., in the department of the Gulf in the beginning of 1864. Much difficulty appears to have been encountered in obtaining these histories; in many regiments there had been a change of surgeons, or the records had been lost or destroyed, so that no satisfactory medical history could be obtained, and more pressing duties or other circumstances soon led to the abandonment of the effort. Hence the medical histories actually collected and preserved among the archives of the office of the Medical Inspector General represent a comparatively small number of regiments, and these for but a portion of the existence of each;

the histories collected by Medical Inspector Vollum terminating in the latter part of 1862, those by Medical Inspectors Mussey and Stipp in the early part of 1863 and 1864, respectively. Notwithstanding their fragmentary character, however, these documents contain some valuable information, and a number of extracts from them will be given in connection with the discussion of the diseases to which they refer.

In the present section the special reports on diarrhœa and dysentery will first be presented, arranged according to the date at which they were prepared. These will be followed by extracts from the sanitary reports, monthly reports of sick and wounded, and medical histories collected by medical inspectors. In the arrangement of these extracts those referring to troops in the Atlantic region will be given first, then those relating to the Central region, and as far as possible the papers coming from each great army or group of armies will be kept together in the order of their dates.

Remarks on chronic diarrhœa, by Acting Assistant Surgeon JAMES P. DEBRULER. *Hospital No. 2, Evansville, Indiana, August* 30, 1862.

Chronic diarrhœa has been extremely common in this hospital, and in many instances so rebellious as to defy all modes of treatment that we could devise.

Symptoms.—Frequent liquid evacuation from the bowels, with or without pain, variable and unnatural appetite, dry glazed tongue, with progressive emaciation, were the most prominent symptoms. Sometimes the patient loathed all food, but most generally the appetite was variable and morbid, craving unnatural and indigestible diet. Acid or sub-acid fruits, pickles, melons, &c., were generally sought for, and if obtained were commonly productive of injury. The tongue, though generally dry, was sometimes moist throughout the disease; it was almost invariably unnaturally clean. The urine was generally scanty, and often loaded with albumen to a remarkable degree. Tenderness along the course of the colon was an almost invariable symptom. In the later stages of the disease the abdomen was not unfrequently covered with an eruption of a dirty drab or slightly copperish color, the spots ranging in size from that of a split pea to a dime or even a twenty-five cent piece. I did not keep notes of this symptom so as to be able to state precisely the proportion of cases in which it occurred, but it certainly was very frequent, and I think was seen in a majority of my cases. Ulceration of the cornea occurred in some eighteen or twenty patients, all of whom were in a state of extreme emaciation. The ulcer was invariably at the same point, namely, in the centre of the lower part of the cornea. It generally occurred in both eyes. The first evidence of the affection observed was a faint whitish streak, which in a day or two was followed by an excavated ulcer with rather smooth, deep, and well-defined edges. The vascularity of the part was but slightly increased, in some instances not at all. The ulcer generally enlarged rapidly until it was large enough to hold a flaxseed or perhaps a half-grain of wheat, after which it usually remained stationary or nearly so. In one instance it perforated the corneæ in both eyes and produced total blindness. With three exceptions the patients thus afflicted died. The exceptional cases are still under treatment; two of them seem to be improving, so much so as to excite hopes that they may recover.

Post mortem appearances.—We have made eleven *post mortem* examinations. In all of them the mucous membrane of the colon and rectum has shown evidences of inflammation, ulceration being distinctly marked in all the cases but two; and in all the cases in which there was ulceration of the cornea, the lower third of the colon and the entire rectum were extensively ulcerated. In two or three instances the bowel was so studded with ulcers that the finger could scarcely be put upon any point of the mucous membrane without touching an ulcer. It strikes me that this constant concurrence of morbid phenomena is worthy of more than a passing thought. I think it will not do to say that the corneal ulceration depended merely upon the arrest of nutrition, for in many of our cases of typhoid fever this seemed quite as extreme as in the diarrhœa, without, however, leading to ulcers of the cornea. I should have stated above that the number of cases examined with reference to this concurrence was seven. It is hoped that others have investigated the subject.

Treatment.—It is perhaps unnecessary to say much under this head. Suffice it to state that mercurials, opiates, and the ordinary astringents have been worse than useless, except so far as the opiates served to relieve pain or temporarily to check the bowels. After much comparative experimenting, preference has been given to sulphate of copper, persulphate of iron, and nitric acid. These remedies variously combined, and given sometimes in large and sometimes in small doses, have, I think, done much good.

Observations on chronic diarrhœa and dysentery, by Assistant Surgeon SAMUEL A. STORROW, U. S. Army. *Eckington hospital, Washington, D. C., November* 17, 1862.

Chronic diarrhœa is the most common disease with which the medical staff of this hospital has to deal. The cases vary considerably in severity and in some minor symptoms, but all have the same general character. Nearly all the patients have been sick some weeks or months before coming here, as they are sent from regimental or general hospitals. In almost all instances the diarrhœa has been contracted while in field service. The general symptoms complained of are frequent desire to go to stool, and small, thin, watery evacuations, accompanied and followed by a good deal of pain and tenesmus. In some cases

the evacuations amount to twenty or more daily. There is often pain in the back, shooting down into the pelvis. Dysuria is frequently complained of, and pain in the lower part of the bladder after the organ is evacuated, and this too when the urine is perfectly normal. Some of the cases have more the character of dysentery than of diarrhœa, but in a hospital like this there is no opportunity to study carefully the alvine discharges, as it is impossible to supply a close stool for each patient. In the dysenteric cases there is great tenesmus, heat and pain about the rectum; the discharges are extremely fetid, and mixed with blood. The general color of the stools in nearly all diarrhœa cases is light, sometimes milky; and many of these patients are more or less afflicted with icterus. There is besides a dry scurfy condition of skin, with a pale waxy complexion, a dry red tongue, and general emaciation and debility. It is not uncommon to have attacks of retching and vomiting, which last a few hours and then subside. The appetite varies; it is generally poor, though sometimes very good. As regards the appearance of the abdomen it is usually flat, dull on percussion, and not tender to the touch; but when the diarrhœa is checked, either spontaneously or from the use of medicines, there is sure to be tympanites and violent pains in the belly, referred mostly to the region of the transverse colon. These pains disappear on the recurrence of the alvine discharges.

I will briefly state the result of my observations in the treatment. I have had but very few recent cases under my care. Those I have had I have treated with a purgative dose of sulphate of magnesia, followed after its operation by five grains of Dover's powder; complete rest being enjoined, with low diet for a day or two. These cases mostly got well without further trouble. Almost all our cases, however, have run on for some weeks or even months before coming here. I have tried almost all the remedies recommended for the disease. I have used opium extensively, both alone and in combination with astringents, in those cases where the discharges were merely watery, and with excellent effects. I have used the vegetable astringents, such as kino, catechu, galls. logwood, &c., and have derived benefit from them occasionally. When the discharges are dark and fetid, I have found great good from ten drops of turpentine in a drachm of mucilage taken several times a day. I have tried the much-vaunted effects of ipecacuanha in large and small doses, but have been disappointed. Observing that Surgeon Charles Tripler, U. S. A., recommends Fowler's solution in chronic diarrhœa, I tried it in a number of cases, and in some with excellent effect. I gave three drops thrice a day. Two cases which had resisted every treatment got well on quarter of a grain of nitrate of silver three times a day. Where the cases are of a dysenteric type, I have been accustomed to wrap the abdomen in warm flannel, and if there be much tenderness to apply dry cups over the tender portions. If the tenesmus does not prevent the introduction of a clyster pipe, a drachm of laudanum in two ounces of starch-water affords prompt relief, or the same effect is secured by an opiate suppository. I have promptly relieved the tenesmus of the bowels and irritability of the bladder by injecting cold water into the gut, sometimes adding a little acetate of lead. I have not used mercurials in chronic dysenteries.

The point in the treatment of chronic dysentery is not so much the particular drug given as the general management of diet and hygiene. The mildest and blandest food should be given, and that in moderate quantity. The patient should have rest as far as possible, and be kept in a dry, moderately warm atmosphere. When stimulants are required, I have found whiskey preferable to all others. Fat meat or fat soup will prevent a cure or even bring on a relapse. I have not had much opportunity of observing the *post mortem* appearances. In three cases which I examined the large intestine was inflamed, and the mucous coat of the sigmoid flexure and rectum thickened.

Remarks on chronic diarrhœa, by Surgeon CHARLES SCHÜSSLER, Sixth Indiana Volunteers. *Hospital No.* 6, *Nashville, Tennessee, December*, 1862.

Diarrhœa, principally in its chronic form, appearing in all its different aspects and stages, required in most instances, and received, a discriminating symptomatic treatment, together with support for the failing strength of the patient. This disease, or rather symptom of diseases, connected with debility of the whole digestive and assimilative organs, and often consecutive to dysentery, presented itself with the prominent symptoms of inflammation of the mucous membrane of the intestine, particularly of its lower portion, which seldom failed to show itself by tenderness on pressure upon the abdomen. There was pain in the right hypochondriac region, frequent micturition of a small quantity of scalding urine, a frequent and small pulse, a tendency to coldness of the extremities, and a dry cold skin, the temperature being highest on the abdomen below the umbilicus. There was usually great thirst; the tongue was clean but of a bright red color, sometimes, however, coated, and there was dryness of the fauces. The evacuations were most frequent at night; they were liquid and often of a chocolate color. The emaciation was great. The respiration was normal when there were no pulmonary complications, but indeed the absence of these complications, as proved by *post mortem* examinations, seemed rather the exception. Nausea and vomiting were sometimes present, and then gastritis was the complication. The appetite, though sometimes lost, was mostly capricious, and any excess in eating increased the symptoms. Mental dejection was a great drawback to the cure, and the repeated relapses fostered despondency. The character of the evacuations varied much, according to the stage of the disease and the diet; they consisted of a bloody serum, clear blood of various shades, often mixed with mucus, a yellowish thin fluid, and debris of the food, which, when solid, was mostly undigested. Sometimes, however, for a day or two the food was well digested and the stools assumed a natural appearance; then all at once, without an apparent cause, they changed, and again became watery, bloody, or mucous. *Post mortem* examinations revealed an inflammatory state of the whole of the mucous membrane of the intestinal tube with the exception of the jejunum. It is true the whole tract was not involved in every individual case, but some portion of it was always affected. In some instances the mucous membrane of the stomach was normal, but in many, traces of inflammation and softening of that membrane were present. The mucous membrane around the cardia and pylorus was most frequently changed, in some instances reddened, and covered with a viscid slime; abrasions and ulcerated spots were sometimes observed. The stomach was mostly empty, with the exception of food or drink taken shortly before death. In one instance I found a scirrhous tumor the size of a pigeon's egg in the stomach. Bile or a bilious fluid was occasionally observed in the stomach. The duodenum was sometimes affected, showing tumescence of the mucous membrane and enlargement of the duodenal glands. Nothing remarkable appeared in the condition of the jejunum, but the ileum constantly offered morbid changes, and, in some instances, isolated patches where

the mucous membrane had entirely disappeared. The lower portion of the ileum was frequently tumefied, its caliber diminished, and the mucous membrane thickened, appearing like velvet of a red, brown, or bluish color. In a number of instances the ileo-cæcal valve was diseased. The colon frequently, and particularly in those cases where dysentery had preceded, presented the greatest amount of change in the condition of its mucous membrane, ulcerated spots or gangrenous disintegration being common. In a few instances where injections of a solution of nitrate of silver had been administered, I believe I could trace its healing influence as far as the injection reached, but above and in the ascending colon the diseased condition was as serious as in other cases. I should have mentioned that intussusceptions of the ileum were observed in three instances. One of the most prominent features of the disease was the amount of bile contained in the gall-bladder. This was almost always found, even when little change could be observed in the liver. The spleen was usually found enormously enlarged. The kidneys also were often enlarged and fatty, so far as could be judged by the naked eye. The pulmonary complications were often proved by dissections to be the consequence of tubercular or other predisposing or pre-existing morbid conditions of the respiratory organs. The frequency and extent of the morbid changes of the organs of respiration were really remarkable, bronchitis and pneumonic hepatization in its different forms being met with in very many cases where diarrhœa had formed the prominent disease. * * * This disease is due to the unavoidable circumstances of camp life, the food, its cooking, irregularity in meals, differences in the drinking-water, fatigue, &c. * * * No specific remedy or routine method of treatment is to be thought of, and great importance attaches to appropriate food and drink.

In the treatment of cases received into hospital, when not contra-indicated, I ordered an opiate in the form of Dover's powder or paregoric. In those cases where irritation of the mucous membrane, from the presence of undigested food or other irritants, was prominent, I gave from one to two ounces of castor oil, with a drachm of spirits of turpentine and some laudanum. I also administered mucilaginous drinks. Sometimes I preferred Epsom salts as a substitute for the castor oil. I gave the patient an anodyne after the operations, and sometimes repeated it, as also the aperient. In the hepatic complications, or when the evacuations were clay-colored or small and painful, containing much mucus, I preceded the above by an alterative, as blue-mass, or mercury and chalk, rarely by small doses of calomel, either combined with opium or followed by a Dover's powder. This plan of treatment was also pursued in bilious diarrhœa, in connection with small doses of ipecacuanha. Local applications to the abdomen were never neglected. Soft poultices of linseed, with or without mustard, aromatic embrocations, or flannel bandages were employed. Ipecacuanha, in small doses, has also been a favorite medicine. When the stomach was decidedly acid I have obtained good results from a mixture of rhubarb and carbonate of magnesia, with mint or camphor-water and paregoric. In those cases in which the evacuations were copious and very frequent, I resorted to astringents, generally combined with opium and aromatic powder. The dilute sulphuric acid which has been so highly recommended I have tried fairly. I have also used the elixir of vitriol with laudanum, one drachm of each in a six-ounce mixture, a tablespoonful three or four times daily, generally conjoined with a strong infusion of oak bark. It has done well in some instances. In those cases where gastrodynia existed, with general nervous derangement and paroxysms of pain not increased by pressure, I have used subnitrate of bismuth, with and without opium, with some success. Solution of acetate of ammonia and laudanum, emollient narcotic cataplasms to the abdomen, benzoic acid, with mucilage of gum arabic and laudanum, have also been used with benefit. Creasote has been a favorite medicine in advanced cases, and where danger of gangrene of the mucous membrane, indicated by the fetid discharges and other collateral symptoms, seemed present. The sulphate of magnesia, in from eight to sixteen-grain doses, with quarter to half a grain of opium, three times daily, and free draughts of flaxseed tea, seemed beneficial in sub-inflammatory cases. A turpentine mixture, consisting of mucilage, oil of turpentine, and olive oil, well rubbed together with cinnamon-water, was often highly beneficial; an opiate was usually added, and sometimes the nitrate of silver in one to five grains to the ounce of mixture. One-eighth to one-half a grain of nitrate of silver with opium, extract of hyoscyamus, or extract of conium, in the form of pills, repeated every eight or ten hours, was regarded as useful in those forms of long standing in which ulceration of the intestine was rendered probable by the symptoms. The preparations of iron, such as the muriate, the sulphate, and the persulphate, either alone or in combination with bitter aromatics, have also proved of value. They required, however, as all the astringents and tonics, good discrimination in each individual case. Tannin was used when the debility was great and the system somewhat prepared by aperients, antacids, bitters, &c. Under the same circumstances I often preferred the acetate of lead from its tendency to increase the secretion of the kidneys, [?] which the tannin rather diminishes. I have also found alum useful. Much depended on the combination of these remedies with aromatics and anodynes, and the form in which they were given. The milder astringents, as kino, catechu, &c., were very useful in combination with bitter extracts. Camphor in small doses was a valuable adjuvant; it formed an important ingredient in our aromatic powder. Spirituous liquors, though indispensable, I cannot regard as curative. Quinine in diarrhœa, though often resorted to, has not fulfilled my expectations in either field or hospital practice; however, infusion and decoction of Peruvian bark, and particularly in combination with iron and aromatics, have proved of much service. Injections per anum, when properly administered, have protracted life in many bad cases, and relieved some patients when internal medicines seemed of little effect. For this purpose I used emollient or astringent emulsions, carminatives, flaxseed tea, sweet oil and laudanum, starch-water and sweet oil, acetate of lead and laudanum, chamomile tea, infusion of mint, &c. Sometimes, where much pain and some tenesmus existed, I used injections containing a small quantity of extract of belladonna with the solution of nitrate of silver. * * * *

Remarks on the treatment of chronic dysentery, by Acting Assistant Surgeon Richard A. F. Penrose.* *Satterlee hospital, Ward II, West Philadelphia, March* 2, 1863.

This hospital has been from its organization in June, 1862, almost entirely filled with chronic cases of disease. It may be really said to receive, as it were, the siftings of other hospitals. All cases of mild character, or of men possessing good constitutions, get well in the hospitals to which they may originally be sent, while those which are severe, or occur in men of

* Professor of Obstetrics, &c., in the University of Pennsylvania.

weak or bad constitution, resist treatment, and after the lapse of weeks or months are crowded out and sent off to try the effects of change of air.

Another peculiarity which strikingly characterizes our patients is the large number of malingerers, whose skill and art in deception have enabled them to convince even competent medical men that they are really suffering from grave disease, when, in fact, they are perfectly well. These, therefore, are the kind of cases we are called upon to treat, viz: on the one hand, cases which have lasted often for months, and have already been subjected to all the ordinary treatment, occurring very frequently in men possessing some radical vice of constitution, and in whom alteration of structure or perversion of function has existed until they have become from habit so fixed as to characterize the individuals almost as if by some natural idiosyncrasy; or, on the other hand, most artful and successful malingerers.

In selecting from such material instructive cases for a report, I have chosen instances of chronic dysentery or diarrhœa, as belonging to the most numerous as well as the most indomitable and intractable of the various diseases coming under our observation, except perhaps rheumatism. These bowel affections, too, are pre-eminently the diseases of the camp, sometimes most fatal in their primary attack, while, in other instances, most surely laying the foundation of disease which ultimately brings the victim to an untimely end. The writer of this communication saw this painfully proved after the Mexican war, during a residency of three years in the wards of the Pennsylvania hospital, some two or three years after the termination of that war. He frequently met cases of chronic dysentery in the hospital wards in men whose sickness originated during the campaign in Mexico. When any of these men died, extensive ulcerations were invariably found in the colon or rectum, or in both, showing why the disease had lasted so long, as well as indicating clearly the rationale of treatment. No opportunity has been afforded for pathological investigations, in the instances of these affections, coming as yet under our observation in this ward of the hospital, save in two cases, and both of these had completely recovered from their bowel affections and died, as the examination after death revealed, from other diseases—one from phthisis and the other from great debility following very severe miasmatic fever contracted on the Peninsula. In both numerous recent cicatrizations of ulcerated surfaces were evident.

The treatment, therefore, which has been carried out in this ward is based on the following view of the pathology of the complaint, viz: that in almost every instance there is chronic inflammation, morbid alteration, or absolute ulceration of the mucous membrane, generally of the large intestine; that, therefore, the treatment ordinarily demanded in the recent or acute stages of the disease is not only useless but injurious, and that our therapeutics, to be successful, must always be applied in reference to the condition of the intestinal mucous membrane. In accordance with these views the treatment has been as follows: First, a most rigid system of dietetics, allowing only bland and unirritating food, and such as would be entirely digested in the upper part of the intestinal tube; in other words, food with no debris to irritate the surface of the large intestine—food, however, most nourishing in its character, as farinaceous preparations, with some milk, whey, eggs, mucilages, essence of beef, chicken soup, &c. In addition to diet, attention to the condition of the surface has been deemed highly important, and hot baths, when procurable, have been largely used. Stimulating frictions with turpentine or capsicum, applied to the extremities and abdomen, have been found very advantageous. Attention to the clothing is also required.

Often in chronic dysentery the most scientific and vigorous treatment will fail unless this rigid system of diet is observed, and the relationship of the skin to the mucous surface ever recollected. Among the medicines used I mention foremost, as almost universally successful, mixtures containing the mineral acids. Of all the cases treated, less than one-sixth perhaps failed to be immediately benefited by them, and in the majority the acid with diet was all that was required to complete the cure, often even in cases that had lasted for months.

Opium, of course, has been necessary, a very favorite method of administration being injections of the tincture into the rectum. When ulcerations of the rectum have been suspected, injections of the sulphate of zinc with laudanum, or nitrate of silver with the same, have been ordered, and often with the happiest results. The vegetable astringents were often used, but were found to palliate rather than cure; they were, however, sometimes directed, as much for a change as for any other reason, in cases which were very chronic, and where the improvement though positive was slow, and where the stomach seemed to become disordered by a long persistence in some one remedy. In a few cases nitrate of silver, in others turpentine, acted very well; in the majority they proved useless or injurious. The salts of iron and the sulphate of zinc were used without satisfactory results. The remedies which have been most positive in their results, after the acids and opium, have been nutmeg and the oxide of zinc, and the author of this communication claims originality in using them in the disease under consideration. The nutmeg was directed as an aromatic and anodyne, conveyed most probably to the ulcerated surface and there producing its beneficial effects. The oxide of zinc was given with the view of having it carried directly to the seat of disease, being perfectly acceptable to the stomach, and if acted on by the acids of the intestines only made more astringent, while its ordinary effects were mild astringency, tonic, and, perhaps, anodyne or sedative effects locally. Most generally these remedies have been used combined, and very few cases have failed to respond to their influence.

With these prefatory remarks, we state that in Ward H there have been treated, from June 9, 1862, to February 1, 1863, forty-seven cases of chronic dysentery and diarrhœa. In some the symptoms were of the gravest character, and the patients seemed reduced to the last extremity, and of these forty-seven, all recovered. Two died, as already stated, from other causes; but in these instances the symptoms during life, and the state of the intestines after death, only proved how absolutely they had recovered from their bowel affection.

In illustration of the views expressed, a history of three of the worst cases received into the ward is appended. These men were extremely ill when admitted, and for a long time had suffered from constant relapses, in which often the remedies before most successful seemed powerless and new plans of treatment became necessary. All of these men finally completely recovered and returned to their regiments.

CASE 1. Ward H, bed No. 17.—Corporal George A. Spring, company G, 27th New York volunteers; admitted July 7, 1862. This man had been taken sick with dysentery in April, 1862, and was sent to his regimental hospital, where he remained until June, when he returned to duty, only however to be seized almost immediately with a severe relapse. He was sent north from Harrison's Landing in the beginning of July. When admitted he was found very much exhausted and emaciated, with

some fever, a frequent pulse, hot dry skin, red coated tongue, and very frequent small stools, which sometimes contained blood. He had a great deal of abdominal pain and soreness on pressure. He was at once placed on the following acid mixture: ℞. Nitro-muriatic acid three drops, tincture of opium five drops, camphor-water half an ounce, water four ounces. The whole given every three hours. Diet: Essence of beef, and arrow-root prepared with milk and water. To take at bed-time an injection of sixty drops of laudanum in half an ounce of water. Under this treatment the man began at once to improve. July 9th: No fever, tongue cleaner, a good deal of pain. The injection enables him to get an uninterrupted night's rest; the stools, originally from twenty to thirty per day, have been reduced to from ten to fifteen in the same period. Medicines continued. July 12th: Very great improvement, tongue almost perfectly clean; but little pain most of the time, but occasionally he suffers considerably; from six to eight stools per day. July 20th: Is almost well. Three or four stools in the twenty-four hours; little pain, good appetite. Continue acid, stop injections. August 1st: Acid reduced to three doses in the day. Patient appears well. August 7th: Is taking no medicine. August 20th: Has had a severe relapse; frequent bloody evacuations, much pain, coated tongue. Renewed the acid, but after a few days' trial found that it failed to produce its former results. August 25th: Worse; tongue red, with a strong disposition to dryness; passages as before. Acid discontinued. ℞. Oil of turpentine ten drops, tincture of opium five drops, syrup of gum arabic half an ounce. Take the whole every two hours. August 30th: Is better; the tongue has lost its redness, is moist; still he has six to eight stools a day and a good deal of pain in the rectum, with much tenesmus. To continue the turpentine in half doses, and to have injections of eight grains of sulphate of zinc and half a drachm of laudanum in four ounces of water, night and morning. This acted very well. September 5th: Reports himself well. No medicine. September 10th: As he is pale and anæmic, ordered ten drops of tincture of chloride of iron six times daily. September 12th: The iron has brought on the old looseness. Stopped at once. To take an injection of laudanum at bed-time. September 28th: Still has from four to six stools per day; tongue red. Ordered turpentine mixture as before. October 6th: About the same. Stop turpentine and take four times daily a pill of nitrate of silver quarter of a grain, opium half a grain, on an empty stomach; also repeated injections of sulphate of zinc. October 8th: The injections have produced a good deal of irritation. Stopped. The nitrate of silver does not seem to do any good. Stopped. No medicine. October 9th: Still has about four to eight stools per day. To try again the turpentine mixture. October 26th: Better, but some looseness. Stop turpentine. Take twelve drops of laudanum and a drachm of the tincture of krameria three times daily. Frictions of turpentine night and morning to extremities and abdomen. November 20th: Has been quite well for some days. No medicine. November 26th: Took cold, and a severe relapse followed. ℞. Castor oil half an ounce, laudanum thirty drops. Very rigid diet, &c. December 1st: Better. Renew the krameria mixture. December 8th: Stop krameria. ℞. Nutmeg ten grains, oxide of zinc ten grains. Take six times daily. This man now rapidly convalesced and became fat and ruddy. Sometimes a slight relapse occurred, for which castor oil and laudanum, with very rigid diet, were directed, the nutmeg and zinc being resumed as soon as the symptoms permitted. December 30th: Perfectly well. No medicine.

Case 2, Ward H, bed No. 47.—Private Joseph Westurn, company G, 16th New York volunteers; admitted July 7, 1862. This man was taken with dysentery in June, and sent to hospital at Harrison's Landing; from thence here. When admitted he presented all the symptoms of severe dysentery, complicated, however, with remittent fever; was very much exhausted and emaciated. ℞. Sulphate of quinia one drachm, dilute sulphuric acid one drachm, water five ounces. Dose, half an ounce every two hours; opiate injection at bed-time; rigid diet. July 12th: All fever has disappeared. Dysenteric symptoms still very severe, but better than when admitted. Quinine stopped—injections continued. The acid mixture used in case No. 1 ordered every three hours. Under this treatment alone this man very rapidly improved, until, by July 26th, he had but one stool in the twenty-four hours. His acid mixture was now discontinued, and as there were some traces of a miasmatic affection hanging about him and he was yet very much prostrated, he was ordered a drachm of compound tincture of cinchona and half an ounce of brandy every four hours, with full diarrhœa diet. From this time he grew better, until by August 11th he seemed perfectly well. August 17th: He has had a severe relapse. ℞. Castor oil half an ounce, laudanum thirty drops; absolute diet. August 20th: Acid mixture. August 22d: Is very much prostrated; feeble, frequent pulse; dry, very red tongue; stools every hour or even more frequently; great epigastric uneasiness. Continue the acid. August 26th: This man now for over a week has been very ill; cannot retain his opiate injections; the acid does not arrest the complaint; tongue intensely dry and red. Stop acid and take turpentine mixture, as given in case No. 1, every two hours. This acted almost like magic upon him. His stools at once diminished in frequency; his tongue in a few days became moist and covered with a thin white fur; his appetite improved. September 14th: Very much better. Still has about four stools daily. Turpentine diminished one-half. September 27th: Is looking very well; begins to pick up flesh; about three to six stools a day; tongue somewhat red; turpentine stopped. ℞. Nitrate of silver quarter of a grain, opium half a grain, four times daily on an empty stomach. This seemed to do much good, and in a few days he appeared nearly well. October 1st: One stool only in twenty-four hours; continue the silver. October 4th: He had a severe relapse; for the next two or three weeks no medicines seemed to produce the slightest effect on him; he had much pain and from six to fifteen stools daily. During this period he used acid mixture, turpentine mixture, pills of two grains of acetate of lead and quarter of a grain of opium every two hours, one drop of creasote in half an ounce of syrup of gum arabic three times daily, also krameria and opium, all with little or no effect. November 3d: All medicine discontinued; rigid diet. November 9th: Ordered ten grains of oxide of zinc six times daily. This acted very well, and by November 15th he was much improved. Ordered now, in addition to the zinc, turpentine frictions to the extremities and belly twice daily. Under this treatment he rapidly improved; had an occasional day or two of looseness, but gained steadily in flesh; became very rosy, and December 11th returned to his regiment.

Case 3, Ward H, bed 23.—Private Eugene F. Wright, company K, 2d Vermont volunteers; admitted July 10, 1862. Has had dysentery since the first of June. Was sent to Harrison's Landing; from thence here. This man was pale and emaciated; had about twenty stools in the twenty-four hours, but no blood and no marked fever; his tongue was thickly coated with a yellowish-white fur, and he had considerable pain. Ordered the acid mixture given in the previous cases. July 20th: Is very much better, not more than five or six stools daily; tongue cleaning rapidly; acid continued, but has only four doses in the

twenty-four hours. August 2d: Diarrhœa checked; no medicine; full diarrhœa diet. August 15th: Some return of the diarrhœa; renew the acid. August 26th: Still too much looseness; stop the acid; try the turpentine mixture. September 7th: Turpentine does but little if any good; stop it. Take, morning and night, the following injection: ℞. Nitrate of silver five grains, laudanum half an ounce, water an ounce. This gave very great relief, and under its use he was brought to one or two stools daily, when it was discontinued. September 15th: ℞. Nitrate of silver quarter of a grain, opium half a grain, four times daily; still some looseness. September 20th: Gave, in addition to the pills of nitrate of silver, ten grains of nutmeg every two hours. This acted remarkably well, and in a week he was reduced to about one stool in thirty-six hours; indeed, frequently he became so constipated as to require a dose of castor oil. October 10th: He has had a relapse, fifteen to twenty stools per day, great pain, &c.; to take a dose of castor oil and laudanum; rigid diet. October 12th: Is better; still ten to twelve stools; renew the acid mixture. October 18th: Still has frequent stools; try the krameria mixture with turpentine frictions. November 1st: Very much better; getting fat. November 9th: Has about six stools per day; stop krameria—continue frictions; take oxide of zinc and nutmeg, ten grains each, every two hours. November 20th: Has from one to four stools per day; continue the zinc and nutmeg, and use krameria. December 10th: Is well; sometimes has a slight looseness, for which he uses the krameria, and also takes regularly ten grains of nutmeg every two hours. This man continued to improve, and became, as the two others, very fat and rosy, and on January 23d returned to his regiment.

Treatment of diarrhœa by Liquidambar Styraciflua, (sweet gum,) by Acting Assistant Surgeon J. V. C. Smith. *St. James hospital, New Orleans, September and October,* 1863.

Among the medical descriptive lists for 1863 are brief reports of thirty-three cases of diarrhœa treated by Acting Assistant Surgeon J. V. C. Smith, in the St. James hospital, New Orleans, with the decoction of the bark of the *Liquidambar Styraciflua,* (sweet gum tree.)

Dr. Smith remarks: "The decoction has been used throughout the entire season in this hospital with marked success. Nearly all the fatal cases of diarrhœa might apparently have terminated more satisfactorily if the patients had been sent more seasonably to the hospital; they are rarely allowed to leave the ranks until they are unable to stand."

The following is a list of the cases:

NAMES.	RANK.	REGIMENT.	COMPANY.	DATE OF ADMISSION.	RESULT.
Charles Howland	Private	14th N. Y. cavalry	A	September 10, 1863	Returned to duty October 1, 1863.

	"				

* According to the hospital register Bennett was discharged for disability October 19, 1863.

† According to the hospital register Kinson returned to duty November 16.

‡ According to the hospital register Campbell was not returned to duty until December 21.

§ According to the hospital register Cromett remained at the hospital until December 4th, when he was furloughed to report at Fort Hamilton, New York harbor.

Treatment of chronic diarrhœa by infusion of Cistus Canadensis, (Helianthemum, U. S. Pharmacopœia.) Extract from the Report of Surgeon JOHN T. HODGEN, U. S. Volunteers. *City hospital, St. Louis, Missouri, for April,* 1863.

I desire to mention the value of the *Cistus Canadensis* as a remedy in chronic diarrhœa. The article has been used at this hospital during the past year in the form of a hot infusion. One ounce of the herb is taken and one or two quarts of boiling water poured on it; to be used when cold, as a drink, by the patient suffering from chronic diarrhœa. Excellent results have followed its use, and I do not hesitate in saying that more patients suffering from this disease have been benefited by it than by all other remedies. The tea has an aromatic and slightly bitter taste, and is taken without a sense of disgust even when continued for a considerable length of time. I am satisfied that the army would be much benefited by its general introduction.

Diarrhœa treated with Injections of Nitrate of Silver at the Judiciary Square hospital, Washington, D. C., during the summer of 1863.

[The case-book of Judiciary Square hospital, Washington, D. C., contains notes of fifteen cases of diarrhœa treated, during 1863, with injections of nitrate of silver, ten or fifteen grains to the ounce of water, with or without laudanum. The first case entered in the book is signed by Assistant Surgeon A. Hartsuff, U. S. A., temporarily acting as surgeon in charge,* by whom it is understood the majority if not all the cases were treated. To the account of each case as recorded in the case-book the subsequent history of the patient, whenever it has been possible to obtain it, is appended.]

CASE 4.—Private Joseph Brinker, company E, 11th Pennsylvania volunteers; admitted April 2, 1863. Compound comminuted fracture of the right femur from a musket bullet. June 15th: The patient was attacked by diarrhœa, having six discharges during the day, for which opium pills were prescribed. June 20th: The diarrhœa still continuing, ordered pills of tannin and opium, one grain each. June 25th: ℞. Persulphate of iron ten grains, opium five grains, capsicum ten grains; make ten pills. Take one every four hours. June 30th: The diarrhœa still continues, averaging five stools daily. ℞. Nitrate of silver fifteen grains, water an ounce. Use as an enema. July 10th: Has had but one passage daily since the enema. [This man was discharged the service March 3, 1865. His right thigh had been amputated in the upper third.]

CASE 5.—Private John Burk, company I, 23d Maine volunteers; admitted April 7, 1863. Diarrhœa of five weeks' standing. Ordered rest, tonics, and astringents. April 9th: There being as yet no improvement, the following was ordered: ℞. Nitrate of silver ten grains, laudanum thirty drops, water one ounce. Use as an injection. This was retained one hour. May 17th: The patient has had for some time but one dejection daily, and may be regarded as cured.

CASE 6.—Private Charles Shank, company H, 4th New York cavalry; age 54; admitted April 29, 1863. Diarrhœa of seven weeks' standing, with from five to eight discharges daily. The stools were thin and colorless. Ordered acetate of lead and tonics. May 1st: The diarrhœa still continues. ℞. Nitrate of silver ten grains, tincture of opium twenty-five drops, water one ounce. Use as an enema. This was retained one hour, after which the patient had but one action per day until he was transferred to general hospital in Philadelphia, several days afterward. [The case-book of Satterlee hospital, Philadelphia, shows that this man was admitted to that hospital May 7th, still suffering from diarrhœa. He also had difficulty in passing water, pain in the region of sacrum, and tenderness along the track of the colon. To take every two hours a pill containing two grains of acetate of lead and half a grain of opium. Mustard plaster to abdomen. Milk diet. May 16th: The patient remains about the same. Discontinue the pills. ℞. Tincture of catechu half an ounce, compound tincture of gentian three ounces and a half. Take a tablespoonful three times daily. May 21st: Bowels constipated. Stop the tincture of catechu and give an ounce of castor oil with twenty-five drops of laudanum. May 25th: The diarrhœa has returned since the oil operated. Renew the tincture of catechu and gentian. May 27th: Substitute Hope's camphor mixture. June 24th: The diarrhœa still continues; the evacuations are abundant and watery. The patient complains of intense rheumatic pains, and a certain stiffness is evinced in all his motions. Ordered ten grains of powdered nutmeg every two hours, and a chloroform liniment. June 27th: The diarrhœa has ceased but the rheumatism still continues. ℞. Iodide of potassium one drachm, wine of colchicum root one drachm, compound tincture of gentian two ounces. Take a teaspoonful three times a day. July 1st: The diarrhœa has returned. The patient complains of cramps in the stomach. Prescribed an aromatic mixture containing ginger and paregoric; subsequently resumed the powdered nutmeg. July 10th: The patient appearing to be nearly well, treatment was discontinued, and he was put on duty in the drug store. July 13: The diarrhœa having recurred, he was returned to the ward and treatment was resumed. He was transferred to convalescent hospital July 30th. The register of the convalescent hospital, corner of 16th and Filbert streets, reports him admitted August 1, 1863. Chronic rheumatism. Transferred to the 2d battalion, Veteran Reserve Corps, November 15th.]

CASE 7. Lieutenant L. E. Holdridge, company L, 4th Pennsylvania cavalry; admitted April 29, 1863. Diarrhœa. The patient had been sick four or five months, having from six to ten passages daily. The stools were thin, almost colorless, and had but little odor. He was put to bed and treated with tonics and astringents without benefit for some days, when the following was ordered: ℞. Nitrate of silver ten grains, laudanum twenty-five drops, water an ounce. Use as an enema. During the twenty-four hours after the injection the patient had but one passage, and that was of more consistence than previous stools. After twenty-four hours the injection was repeated, and the diarrhœa was completely checked. [The patient was transferred to Philadelphia May 6th. The records of Satterlee hospital, Philadelphia, show that this man was admitted May 7th—diagnosis, diarrhœa. Returned to duty May 18th.]

CASE 8.—Lieutenant Clark E. Bates, company I, 2d Rhode Island volunteers; admitted May 8, 1863, with compound comminuted fracture of the right thigh by a musket bullet. Diarrhœa set in June 20th. Ordered thirty drops of laudanum,

* In the absence of Assistant Surgeon E. J. Marsh, U. S. A.

followed by chalk mixture. June 29th: The diarrhœa still continues, the passages averaging four daily. ℞. Nitrate of silver ten grains, laudanum twenty-five drops, water one ounce. Use as an enema. This was retained one hour. July 2d: Has had three passages to-day. Repeat the injection. July 7th: Has had but one or two passages of good consistence daily since the last note. [This officer died July 18, 1863, from the effects of his wound.]

CASE 9.—Private William Moss, company F, 122d New York volunteers; admitted June 13, 1863. Diarrhœa consecutive to typhoid fever. The patient was unable to give any account of his sickness, and had a profuse diarrhœa, the discharges being involuntary. ℞. Nitrate of silver ten grains, laudanum twenty-five drops, water one ounce. Use as an enema. This was retained a quarter of an hour. June 14th: Since the last note the patient has had four large and thin discharges from the bowels. ℞. Nitrate of silver fifteen grains, water one ounce. Use as an enema. June 17th: Has had but one discharge since the injection; it was large and thin. June 20th: Four discharges within the twenty-four hours. ℞. Nitrate of silver twenty grains, water one ounce. Use as an enema. June 22d: Has had but one action from the bowels since the last note. July 1st: The patient has had but one stool daily since the 22d. His fæces are now consistent and healthy in appearance. [This man deserted from hospital September 30th.]

CASE 10.—Private Horace O. Hill, company I, 27th Connecticut volunteers; admitted June 13, 1863. Chronic diarrhœa, from which he has suffered four months, having from six to twelve passages daily. Ordered the following: ℞. Nitrate of silver ten grains, laudanum twenty-five drops, water one ounce. To be used as an enema. This was retained half an hour. June 14th and 15th: The bowels were not moved. June 16th: There were three movements this morning, being the first since the injection. ℞. Nitrate of silver fifteen grains, water one ounce. Use as an enema. June 20th: The patient has now but one consistent stool per day. July 1st: Transferred to another hospital. [The records of Lovell hospital, Portsmouth Grove, Rhode Island, show that this man was admitted to the hospital July 3d—diagnosis, chronic diarrhœa—and that he was discharged the service July 30th, by reason of expiration of term of service.]

CASE 11.—Private David Watson, company D, 16th Massachusetts volunteers; admitted June 17, 1863. Diarrhœa of ten weeks' standing, with from six to eight discharges per day. Gave astringents, such as tannic acid, acetate of lead, &c., with opium, but effected no change in his condition. June 30th: Ordered the following: ℞. Nitrate of silver ten grains, laudanum twenty-five drops, water one ounce. To be used as an enema. The injection was retained an hour. June 21st: The patient seems much better, and has had but one passage from the bowels since the last note. The fæces are more consistent. July 1st: There has been but one stool per day since the injection. The diarrhœa may be considered cured. The patient is transferred to a northern hospital to recruit his strength. [The register of Lovell hospital, Portsmouth Grove, Rhode Island, shows that this man was admitted to that hospital July 3d—diagnosis, diarrhœa—and that he was transferred to the Veteran Reserve Corps March 31, 1864, on account of the loss of his left thumb by amputation.]

CASE 12.—Private Wellington McSparren, company F, 169th Pennsylvania volunteers; admitted July 11, 1863, with diarrhœa of three weeks' standing. ℞. Nitrate of silver ten grains, laudanum twenty-five drops, water one ounce. Use as an enema. This was retained one hour, after which the patient had but one passage daily until July 14th, when he had seven passages during the twenty-four hours. The injection was then repeated, after which the patient had but one stool daily, and was discharged cured July 21, 1863.

CASE 13.—Private Mahlon Shaffer, company C, 167th Pennsylvania volunteers; admitted July 12, 1863. Diarrhœa of three months' standing. The discharges numbered from five to ten per day; they were thin and colorless. Astringents were employed without benefit for several days, when an enema of fifteen grains of nitrate of silver, dissolved in an ounce of water, was administered, with the effect of promptly checking the diarrhœa. The patient was returned to duty August 7th.

CASE 14.—Private Thomas H. Ande, company G, 178th Pennsylvania volunteers; admitted July 14, 1863. Diarrhœa of five weeks' standing, with from four to ten passages daily. The patient was emaciated and had no appetite. Rice diet was ordered, perfect rest enjoined, and astringents prescribed—all to little purpose. Ordered the following: ℞. Nitrate of silver ten grains, laudanum twenty-five drops, water one ounce. Use as an enema. This was retained half an hour, after which the patient went ten hours without a stool. The passages were then altered in character, being thicker and more natural. From this time he had only one stool daily. Returned to duty July 20th.

CASE 15.—Private Lewis Huber, company G, 179th Pennsylvania volunteers; admitted July 14, 1863. Diarrhœa of three weeks' standing; four to eight thin, colorless passages daily. Ordered perfect rest, astringents, and milk diet, without benefit. July 16th: Ordered the following: ℞. Nitrate of silver ten grains, laudanum twenty-five drops, water one ounce. Use as an enema. This was retained half an hour, after which the patient had but one passage daily, and was returned to duty cured July 20th.

CASE 16.—Private David F. Burt, company A, 130th New York volunteers; admitted July 18, 1863. Diarrhœa of seven months' standing. The patient was weak, emaciated, and had no appetite. He had from six to twelve passages daily. Ordered good diet, stimulants, and astringents—tannin, opium, lead, &c.—which diminished the number of discharges to from four to eight. In this condition the patient remained without further amendment until July 31st, when an enema of fifteen grains of nitrate of silver, dissolved in an ounce of water, was ordered. This was retained about an hour. From this time the evacuations became natural in appearance, and were reduced in number to one or two daily. The patient was returned to duty September 24, 1863.

CASE 17.—Corporal John Webster, company G, 2d New York cavalry; admitted July 24, 1863, from Yorktown. Diarrhœa. The patient had been sick about four weeks, and was weak and emaciated. He had from four to fifteen thin, light-colored, nearly odorless stools daily. July 25th: Ordered quinine, with tannin and other astringents combined with

opium. This treatment was continued three days without benefit. July 29th: Ordered the following: ℞. Nitrate of silver fifteen grains, water one ounce. Use as an enema. This was retained twenty-five minutes. The stools were at once reduced to but two daily, and became quite consistent. The patient soon recovered entirely. [He deserted December 31, 1863.]

CASE 18.—Private Henry S. Davis, company B, 49th Pennsylvania volunteers; admitted September 10, 1863. Diarrhœa of four months' standing. The patient was much emaciated, and had from five to ten passages daily. Astringents were administered without effect, and the first injection of nitrate of silver, fifteen grains to the ounce of water, produced but little benefit. The injection was repeated, when the patient began to improve, and after a third repetition recovered completely. Transferred to general hospital in Philadelphia September 23d. [The register of Mower hospital, Philadelphia, shows that this man was admitted to that hospital September 24th—diagnosis, chronic diarrhœa—and was returned to duty November 16th.]

Letter to the SURGEON GENERAL *on the use of Peanuts (nuts of Arachis hypogœa) in the treatment of diarrhœa and dysentery.*

WASHINGTON, D. C., *August* 31, 1863.

SIR: That pest of the army, diarrhœa or dysentery, can be relieved, in my opinion, in a majority of instances, by letting the person eat a gill or so of peanuts cooked in the ordinary manner. I had an ordinary diarrhœa or dysentery, caused by eating too many vegetables or by the heat, or both together, and after trying laudanum, essence of ginger, and other remedies to no purpose, concluded to eat some peanuts, and after eating a gill the diarrhœa was gone, and another gill actually constipated me. From this I learned that cooked peanuts are an astringent, of which I was not before aware.

In my opinion, if peanuts slightly roasted were placed in our hospitals in small quantities, they would prove the cheapest and best food-remedy for looseness of the bowels that has as yet been tried. If such should prove to be the fact in the hospitals, the peanuts might be issued regularly in the army either as a ration or as a sanitary article of food. Will you please give them a trial?

Very respectfully, your obedient servant,

A. WATSON.

[This letter was referred to Assistant Surgeon A. Hartsuff, in charge of Judiciary Square hospital, Washington, D. C., with directions to secure a sufficient supply of peanuts to test their effects. The following is his report to the Surgeon General:]

JUDICIARY SQUARE HOSPITAL, WASHINGTON, D. C., *September* 29, 1863.

SIR: Agreeably to special orders I have the honor to report that I have used peanuts in several cases of acute and chronic diarrhœa and dysentery and find them to be utterly worthless in either stage of each disease. In one of the four acute cases in which they were used they seemed to produce temporary relief, the alvine discharges diminishing from twelve to three in twenty-four hours; but although the peanuts were continued the diarrhœa became as bad as ever, and other remedies became necessary. In one or two of the chronic cases they seemed to aggravate the disease, and in no case did they produce any permanently good effects.

Very respectfully, your obedient servant.

A. HARTSUFF,
Assistant Surgeon U. S. Army.

Report on the use of Sub-nitrate of Bismuth in the treatment of diarrhœa, by Surgeon T. RUSH SPENCER, U. S. Volunteers.

SECOND DIVISION HOSPITAL, ALEXANDRIA, VIRGINIA, *September* 24, 1863.

SIR: I have the honor to furnish herewith a statement of the results of the treatment of seventy-six cases of diarrhœa with sub-nitrate of bismuth, given in drachm doses, one dose daily.

The number of cases was seventy-six, of which sixty were chronic and sixteen acute. In seventy-one cases the disease was checked, and five still remain under treatment. The duration of treatment necessary to check the disease was one day in twenty-three cases, two days in nine cases, three days in fifteen cases, four days in seven cases, five days in six cases, six days in six cases, seven days in one case, and eight days in four cases.

The impression upon the minds of all the medical officers in this division is very strongly in favor of the bismuth treatment. It has certainly proved the most successful of any hitherto employed, and is worthy of further trial. Dr. Trask has rendered a service to the profession by calling attention to this remedy. I trust this will prove a sufficient explanation for so soon making another special requisition for so large an amount.

Very respectfully, your obedient servant,

T. RUSH SPENCER,
Surgeon in charge.

Surgeon R. O. ABBOTT, U. S. Army, *Medical Director.*

[The foregoing report of Surgeon T. Rush Spencer was referred to in Circular No. 6 (p. 126). November 2, 1868, during a visit to the Museum, Dr. Spencer explained that he did not intend in it to represent the patients as being permanently cured, but simply as having the discharges from the bowels checked for the time being. He also stated that subsequently receiving a supply of the sub-carbonate of bismuth in lieu of the sub-nitrate, he did not find it so efficacious.]

Remarks on chronic diarrhœa, by Surgeon Benjamin Woodward, 22d Illinois Volunteers, *January*, 1864.

In September, 1861, Surgeon James Simons, U. S. A., Medical Director at Cairo, Illinois, directed me to take charge of the depot hospital at that point. There were, as nearly as I can remember, one hundred and sixty-eight patients, most of them suffering from diarrhœa or dysentery. A large proportion had contracted the disease while on duty in the malarious swamps of that region of Illinois and the adjacent parts of Missouri and Kentucky. The appearance of these patients was anæmic and bloodless, with lips and conjunctivæ blanched, muscular tissues wasted, pulse rapid and feeble, tongue, in the recent cases, of a dirty lead color, generally furred at the root, while in those in whom the disease had become chronic it was red or purple, smooth, glossy, and presented a varnished look; it was, however, but rarely dry. The skin was harsh and dry, the urine scanty, limpid, and nearly free from color; dejections frequent, watery, almost destitute of color, and nearly every case complicated with either hemorrhoids or a tendency to prolapsus ani. For some time previously one of two plans of treatment had been employed in the hospital. The first consisted in the administration of astringents, usually dry persulphate of iron in from three to five-grain doses, with from one to three grains of opium, every two or three hours. The other plan was "Surgeon Tripler's saline mode." The diet of all the patients was alike—tea and coffee and toast twice a day, and meat and potatoes for dinner.

The history of nearly every case showed it to have had a malarious origin, while the character of the dejections and other symptoms proved that there was hepatic derangement. Generally the liver was torpid, there being little or no bile in the fæces. A very large number of cases complained of a sense of fulness in the abdomen, particularly in the region of the liver. On endeavoring to analyze and classify these cases, the evidence was conclusive to my view that in the latter group of cases, though the abdomen was flaccid, there was congestion of the liver and portal circulation, and I selected these for a full trial of Tripler's treatment, and ordered an ounce of sulphate of magnesia, a grain of tartar emetic, and four ounces of water. Of this mixture one-fourth was given every two hours, and as soon as the bowels were moved (and scybala were generally brought away in large quantities) gave four powders, consisting each of five grains of quinine, half a grain of ipecacuanha, and one of opium—one to be taken every three hours; or, when the liver was more than usually torpid, substitute for these four powders, consisting each of five grains of quinine, three of mercury with chalk, and half a grain of opium—one to be taken every four hours. As soon as the salines had operated well, there was generally relief from the sense of fulness and oppression in the portal region. I did not repeat the salines unless this sense of oppression returned, which was rarely the case, but relied on an after-treatment with quinine, ginger, and stimulants, and as generous a diet as the stomach would bear.

In the other class of cases I relied on quinine, gallic acid, when I could get it, and when I could not, tannic acid, and mercury with chalk. My experience with opium in camp diarrhœa has not been satisfactory, unless the liver was too active, when it moderated that action. In old chronic cases, when the tongue had become smooth and glossy, iron by hydrogen, with the bitter tonics, have fully answered my expectations. I made many examinations of the bodies of those who died from camp diarrhœa, and in every case in which the tongue had assumed the varnished appearance above alluded to the whole intestinal canal was more or less diseased, and the patients died of starvation, digestion being impossible. The blood in these cases was like what I have seen in Asiatic cholera. The mucous coat of the intestines was blanched, in many cases abraded or ulcerated, the solitary glands invariably enlarged, while the mesenteric glands were enlarged and softened.

I beg leave here to call attention to a form of diarrhœa which has been very common at the hospital at Tullahoma, Tennessee, during the fall of 1863. When the Eleventh and Twelfth Army Corps came from the army of the Potomac to join the army of the Cumberland, they left a large number of sick at this hospital. Many of these were cases of diarrhœa. To the practiced eye it was not difficult to detect scorbutus. There were frequent dejections, wandering pains in the muscles of the limbs, particularly those of the thighs and legs, lumbago, lassitude, and in many cases sponginess of the gums, and spots of purpura. These men had for a long time been without vegetables and the blood had become depraved. Having served in the army of General Pope in the spring of 1862, in the operations before New Madrid, Missouri, and Island No. 10, while the blockade of the Mississippi river existed, I had many opportunities of seeing this form of diarrhœa, the troops for many weeks being confined to a diet of bacon, hard bread, and coffee. Every known means of medication was resorted to, including the potash treatment, but it all proved nugatory, and it was not until vegetation commenced and the men could gather a few greens that any amendment took place. When the Eleventh and Twelfth Corps came here with this form of diarrhœa no form of medication was resorted to, but they were given all the vegetables and fruits they could eat. Every case recovered. It was found that when the vegetables were given to them in the raw state the effect was more marked. Potatoes, onions, and tomatoes sliced in vinegar were the most grateful and efficacious. After the battles of Lookout Mountain and Missionary Ridge, in November last, ninety-six wounded were brought from the front to this hospital. Many of them had scorbutic diarrhœa. In no case were medicines administered for it, but a fresh vegetable and fresh meat diet was relied upon, and it was remarkable to see how soon not only the diarrhœa abated, but the wounds took on healthy action.

Extract from the report of the inspection of the general hospital at Chattanooga, Tennessee, by Medical Inspector Edward P. Vollum, U. S. A., *January* 15, 1864.

The want of success attending the great variety of medical treatment that has been tried in chronic diarrhœa, and its high rate of mortality, has very generally discouraged the surgeons in the employment of medicines of any kind except by enema. Consequently, attention is directed in the Department of the Cumberland to the value of dietetic measures, and I learn that more success has been obtained than ever before, in the management of chronic diarrhœa especially. At Division No. 2, Surgeon C. N. Ellinwood, 74th Illinois volunteers, claims excellent success in this obstinate complaint by the employment of well-

prepared digestible food, with enemas of nitrate of silver, two grains to the ounce. This treatment is particularly applicable in those cases where the rectum has become thickened, ulcerated, eroded, &c., as manifested by the foul, mucous, dark stools, often containing patches of membrane. Dr. Ellinwood employs a conserve of beef made by mixing the finely grated fibre of muscle with currant or gooseberry jelly, said to be more palatable and digestible than beef-tea. From two to twelve ounces of this are given daily. The ordinary beef-tea, made fresh three times per day, is also employed. Before the enema is given the rectum is washed out with tepid water. The enemas are continued twice a day till the stools cease to be bloody. Where there is not much evidence of organic change in the intestines and the stools were acid, mercury with chalk, and ipecacuanha are often employed with benefit. Opium is sometimes added to allay tenesmus.

Surgeon John L. Teed, U. S. volunteers, at Division No. 4, also employs the dietetic method in chronic diarrhœa with benefit. He has separated such cases under the charge of one surgeon, who is directed to make careful observations and records of his cases.

I have striven assiduously to inculcate the advantage of digestible and palatable food in chronic diarrhœa over any plan of medication, and it is gratifying to see that others have arrived at the same conclusion, having set to work earnestly at it from their own promptings.

Report on the use of Bromine in cases of chronic diarrhœa and dysentery, treated in prison hospital, Rock Island, Illinois, by Acting Assistant Surgeon H. F. Gilbert, *November* 14, 1864.

* * * September 5, 1864, I organized a ward capable of accommodating forty-three patients, and up to the 20th of October ninety have been admitted; forty-seven were cases of chronic diarrhœa, thirty-one of acute dysentery, and twelve acute diarrhœa.

Treatment.—℞. Bromine six drops, bromide of potassium fifteen grains, water one ounce. I administered one drachm of this solution every two hours during the day, without regard to stage, complications, character of discharges, or constitutional symptoms, with the following results: Returned to barracks cured, seventy-nine; remaining in ward, ten; died, one. Those remaining are suffering from chronic diarrhœa complicated with scurvy, very much emaciated, and will not be fit for duty within sixty days. All such are ordered south for exchange. I am of the opinion that they would finally recover were they kept on the bromine treatment.

The *post mortem* made on the body of the case resulting in death shows its complications, and the difficulty of treating such cases is apparent to the most casual observer. [Case 78, *Infra.*] Private William Baily, company B, 2d Kentucky cavalry, transferred to my ward October 11, 1864, died October 19th. *Autopsy* thirty-six hours after death: Body greatly emaciated. There were strong pleuritic adhesions on both sides. Miliary tubercles were numerously scattered through both lungs, most abundantly at their apices; the parenchyma between the tubercles was indurated by pneumonia, and of a gray color from pigmentary deposit. The heart was very large and fatty. The liver was enlarged and greatly altered in shape; it was of a dusky color, and on section presented semi-translucent edges. The stomach was ulcerated to some extent. The small intestines were œdematous, and their coats generally thickened. About the middle third of the jejunum there was an intussusception of about two inches in length; immediately above and below, two lumbricoid worms were found, the smaller above and the larger below. About the invagination the gut was greatly congested. The mucous membrane of the large intestine was extensively ulcerated, thickened, and disorganized. The other organs were healthy.

I found the acute cases, both of diarrhœa and dysentery, recovered with greater rapidity than the chronic. The progress of the latter, in my opinion, was retarded in a great measure by the too frequent use or administration of the remedy; for in the extremely emaciated cases the medicine would cause a slight sickness of the stomach, thereby preventing the patient from taking the amount of nourishment necessary to sustain life; but when administered at long intervals no such symptoms occurred, the digestion improved, griping and tenesmus subsided, and the discharges gradually became more natural, until the patient was entirely restored to health.

It is proper to state that the chronic diarrhœa cases were the worst that could be selected from the hospital; most of them were of over twelve months' standing. The patients were greatly emaciated; the tongue dry; and the contents of the bowels passed off, as they lay in bed, without intermission.

In those cases complicated with chronic inflammation of the lungs and lining membrane of the bronchial tubes, and even when the lung was dense, solid, and impervious to air in some parts, (which is more or less the condition of extremely emaciated diarrhœa subjects,) I found the pains in the chest and dyspnœa, together with the troublesome cough, entirely disappear in a very short time, and the patient expressing himself as "feeling like a new man."

Whether the bromine acted directly upon the diseased pulmonary tissue by inhalation, or in some other way, remains to be ascertained. As it is wonderfully volatile I am inclined to the opinion that its good results are due to the direct application of the vapor to the tissue involved—a method in the treatment of chest diseases which, I confess, I am surprised at the profession viewing with so much indifference. Be this right or wrong, certain it is, I have been astonished at the happy results in such cases as the above treated with bromine.

Bromine is a new remedy, its status as yet remaining unknown or unsettled, and we have but imperfect data from which to draw our conclusions. Still, I am impelled from personal observations and experience to assert that in bromine we have an agent certain in its effects to cure all cases of diarrhœa or dysentery, I care not of how long standing, if the patient has sufficient vitality left to sustain life five or six days; and a perfect restoration to health may be relied upon, unless the disease is complicated with some serious malady.

I am aware that this is a sweeping assertion, yet I doubt not that the time is not far distant when the medical profession will verify what I am now saying. I herewith append a note from Dr. Salter, who has been using bromine in the barracks:

Dr. H. F. GILBERT. ROCK ISLAND, ILLINOIS, *October* 14, 1864.

DEAR SIR: Since I had the pleasure of listening to your remarks on the use of bromine in dysentery and diarrhœa I have been testing for myself the efficacy of that medicine in the two diseases above mentioned. I have been prescribing it in the prison barracks, where the situation and attending circumstances are by no means favorable for the administration of any remedy, and least of all in diarrhœa and dysentery; notwithstanding, I have found it in many instances of the above complaints to have answered a most excellent purpose, and I believe it to be a very valuable remedy. I do not think that I ever tried any one article of the *materia medica* which has proved so satisfactory under all circumstances. There have been several cases apparently not benefited by its administration, thus proving that it is not a specific; yet I cannot say that, under more favorable circumstances, it might not have been more satisfactory even in these cases, and I would here remark, also, that these cases had not been relieved by any previous course of treatment. I would say, in conclusion, that in the treatment of these two diseases I have found in bromine a most valuable remedy, and that in many very severe cases I have been both surprised and pleased with its efficacy, and deem it well worthy the attention of the profession. Hoping that the fullest success may attend you in your efforts to ascertain the full force of bromine and its applicability to the various diseases now being treated by you,

I am, sir, with much respect, yours truly, &c.,

H. F. SALTER,
Acting Assistant Surgeon U. S. Army.

In conclusion, I would say that the medical descriptive lists of the above cases have been carefully kept, and in due time they will be published, that the medical profession may judge of the character of the cases treated, and of the power of bromine in effecting astonishing cures.

[The foregoing report was indorsed as follows:

November 14, 1864.

Respectfully forwarded, and commended to the notice of the Medical Director.

WILLIAM WATSON,
Surgeon U. S. Volunteers, in charge.

December 29, 1865, Surgeon Watson, during a visit to the Surgeon General's Office, informed the editor that more extended experience in the hospital at Rock Island did not fulfil the sanguine expectations entertained by Dr. Gilbert.]

Cases of diarrhœa and dysentery treated with Bromine during 1864, *at Rock Island prison hospital.*

[The case-book of the Rock Island prison hospital contains Dr. H. F. Gilbert's reports of fifty-seven cases of diarrhœa and dysentery supposed to have been cured by the use of bromine, as described in the last report. These are appended, together with such cases of the same disease which proved fatal under the bromine treatment, as are recorded in the book.

The following table shows the number of prisoners of war confined at Rock Island, and the number of admissions into hospital, and deaths from diarrhœa and dysentery monthly, from August, 1864, to January, 1865, inclusive; this being the period during which Dr. Gilbert's cases occurred:

MONTH.	1864.										1865.		TOTAL.	
	August.		September.		October.		November.		December.		January.			
Mean Strength	8,361		8,236		7,924		6,974		6,461		6,419			
	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.
Acute Diarrhœa	125	.....	58	2	38	.....	95	2	286	4	102	2	704	10
Chronic Diarrhœa	62	28	66	8	39	8	61	8	72	23	42	27	342	102
Acute Dysentery	897	25	396	14	56	1	60	.....	110	2	24	.....	1,543	42
Chronic Dysentery	5	1	25	1	5	2	2	.....	2	.....	1	1	40	5
Total	1,089	54	545	25	138	11	218	10	470	29	169	30	2,629	159

The extent to which the bromine treatment was used during this period does not appear in the report. Dr. Gilbert's cases are the only successful ones recorded.

In some of the cases Dr. Gilbert substituted a weak solution of iodine; two grains of iodine dissolved in an ounce of water by means of iodide of potassium. The dose was ten drops three times a day. The reason alleged for the change in the case of McDaniel, case 80, was the temporary exhaustion of the supply of bromine.

An examination of these cases shows that Dr. Gilbert's enthusiastic hopes are not supported by the record. Of the fifty-seven cases reported by him in the case-book as cured, eleven were shortly after readmitted with the same disease; two others were dead at the time Dr. Gilbert dates his report, (case 44, Pitts, died October 30th, and case 59, Meigs, November 2d;) and two more died subsequently, (case 56, Whitehead, December 13th, and case 51, Murray, January 18, 1865.)

Besides these fatal cases, the case-book contains reports by Dr. Gilbert himself of four other fatal cases, three of whom were dead at the date of his report, (case 76, Jones, October 1st; case 77, Nelson, October 2d; and case 80, McDaniel, November

4th;) so that if Dr. Gilbert had examined the record instead of merely trusting to his memory, as he appears to have done, his report should have contained six fatal cases instead of one. The case-book also contains the records of eleven other fatal cases treated with bromine; six of these were recorded by Dr. Salter, whose letter is contained in Dr. Gilbert's report; four by Dr. Young, and one by Dr. Mathews. It appears by the record that four of these cases (case 81, Green; case 82, Gilliom; case 83, Fisher; and case 87, Burke) had been treated by Dr. Gilbert with bromine.]

Cases reported by Dr. GILBERT *as cured.*

CASE 19.—Private Matthew N. Goss, company B, 8th Georgia battery; age 28; admitted June 16, 1864. Chronic diarrhœa of eighteen months' standing. Was first seen by the reporter September 9th. September 14th: Ordered a drachm of solution of bromine every four hours. September 16th: The same every two hours. September 23d: The operations are not so frequent, but they are still thin, watery, and light colored. October 24th: Returned to the barracks cured.

CASE 20.—Private John McLaughlin, company C, 18th Alabama; admitted August 10, 1864. Acute dysentery. The operations were very small, bloody, and frequent. There is no record of his treatment until September 16th, when he was put upon solution of bromine. He immediately began to improve, and was discharged, cured, September 26th. [According to the hospital register this man was again admitted with diarrhœa November 7th, and returned to the barracks January 3, 1865.]

CASE 21.—Private James R. Robinson, company F, 33d Georgia; age 32; admitted August 13, 1864. Chronic diarrhœa of twelve months' standing. The patient was treated with astringent pills, pills of acetate of lead and opium, pills of quinine, opium, and capsicum, tincture of the chloride of iron, &c., until September 14th, when he was put upon the use of solution of bromine. September 20th: Has improved rapidly. But two stools in the last twenty-four hours; these, though thin, are natural in color. September 22d: Continues to improve. September 28th: Returned to barracks cured.

CASE 22.—Sergeant John W. English, company A, 52d Georgia; age 20; admitted August 14, 1864. Acute dysentery. Had been sick about twelve days. The stools were very frequent, painful, and chiefly composed of blood. The patient was treated with astringent pills, pills of quinine, capsicum and opium, pills of nitrate of silver and opium, &c., until September 14th, when solution of bromine was prescribed. September 22d: Has improved somewhat. The stools are less frequent, not so painful, and contain no blood, but are still small. The soreness of the abdomen is diminishing. October 9th: Continues to improve slowly. The passages are more natural, but still frequent. October 21st: Substituted ten drops of solution of iodine, two grains to the ounce, three times a day. November 6th: Returned to the barracks cured. [According to the hospital register this man was returned to the barracks November 22d.]

CASE 23.—Private Phineas Wilds, company A, 3d Florida; age 33; admitted August 14, 1864. Chronic diarrhœa. The patient stated that he had suffered from diarrhœa at intervals for the last fourteen months. At the time of admission he had from eight to ten rather large, thin, watery, light-colored passages daily. He was treated with astringent pills, pills of nitrate of silver and opium, &c., without benefit. September 13th: He was put upon the solution of bromine. September 20th: Has improved rapidly; has now but one or two passages daily, and these are quite natural in appearance. September 26th: Returned to the barracks cured. [According to the hospital register this man was readmitted, with the same disease, October 27th, and returned to the barracks November 28th. He was again admitted, also for the same disease, December 11th, and returned to the barracks March 4, 1865.]

CASE 24.—Private William W. Williams, company I, 31st Alabama; admitted August 17, 1864. Acute dysentery. This man had been sick five days when admitted. He had from twelve to fifteen small, bloody passages in the twenty-four hours. He was treated with astringent pills, nitrate of silver and opium, sulphate of magnesia, aromatic sulphuric acid, &c., without benefit. September 16th: A drachm of bromine solution was ordered every two hours. September 20th and 21st: Rest without medicine. September 22d: Five grains of blue pill. September 24th: Resumed the bromine mixture. September 26th: Returned to the barracks cured.

CASE 25.—Sergeant J. D. Drummond, company D, 34th Georgia; admitted August 20, 1864. Chronic diarrhœa of four months' standing. Has six to eight thin, watery stools daily. Has been under medical treatment most of the time. After his admission to hospital, was treated with pills of nitrate of silver and opium, &c., but without benefit. September 14th: Was put upon a drachm of the solution of bromine every two hours. He improved rapidly, and September 28th was returned to the barracks cured. [According to the hospital register this man was readmitted, with diarrhœa, October 17th, and returned to the barracks November 4th.]

CASE 26.—Private Albert Jenkins, company A, 40th Alabama; age 26; admitted August 20, 1864. Chronic diarrhœa of ten months' standing. The complaint was first developed immediately after a fatiguing march; has been under medical treatment ever since, but without permanent benefit. After his admission to hospital he was treated with astringent pills, brandy, &c. Was first seen by the reporter September 16th. At that time he had from six to eight thin, watery operations in the twenty-four hours. Some of the stools resembled the white of an egg. To take a drachm of solution of bromine every hour. September 24th: Has improved rapidly; the stools are less frequent and more natural; he had but three in the last twenty-four hours. October 9th: Has continued to improve since the last report. The bowels are now regular. Returned to barracks, cured, October 24th. [According to the hospital register this man was readmitted, with diarrhœa, October 28th, and was returned to the barracks March 17, 1865.]

CASE 27.—Private John R. Combs, company D, 4th Florida; age 20; admitted August 25, 1864. Chronic diarrhœa of thirteen months' standing. Has been under medical treatment most of the time. When admitted he had from eight to ten stools daily, and when first seen by the reporter, September 16th, was in the same condition. The solution of bromine was then

prescribed, and the patient immediately began to improve. September 30th: Has continued to improve. Is now on full diet. October 22d: Bowels tolerably regular and stools quite natural. Discontinue medicine. November 6th: To take ten drops of the iodine solution, two grains to the ounce, three times daily. November 20th: Resume the solution of bromine. December 29th: Is quite well, and is detailed as a nurse.

CASE 28.—Private Jackson Brantly, company E, 18th Arkansas; age 32; admitted August 25, 1864. Diarrhœa of two months' duration. Had from eight to ten operations daily. Was treated with pills of nitrate of silver and opium, pills of quinine, capsicum, and opium, &c. Was first put upon the bromine solution September 12th; at that time he had one or two operations every hour, and the stools were often passed in bed. September 22d: Has improved very rapidly. Had but two operations in the last twenty-four hours. October 9th: Has continued to improve since the last note; has been four or five days on full diet; bowels regular, passages natural. October 24th: Returned to the barracks cured.

CASE 29.—Private George W. Bond, company A, 1st Tennessee battery; age 32; admitted August 27, 1864. Chronic diarrhœa of seven months' standing. Had from eight to ten thin, watery operations daily. Was treated with pills of nitrate of silver and opium, &c., until September 14th, when a drachm of the bromine solution was ordered to be taken every four hours. October 22d: Substituted ten drops of iodine solution, two grains to the ounce, three times daily. November 14th: Resumed the solution of bromine. November 20th: Discontinued medicine. November 22d: Returned to the barracks.

CASE 30.—Private William Lawler, 10th Confederate cavalry; age 21; admitted August 28, 1864. Chronic diarrhœa of eight months' standing. The stools averaged five daily, and consisted, according to the patient, of a "mushy" substance. There is no record of his treatment in hospital until September 16th, when solution of bromine was prescribed. He then improved rapidly, and was discharged, cured, October 9th. [According to the hospital register this man was returned to the barracks December 25th.]

CASE 31.—Private Thomas A. Scott, company K, 43d Tennessee; age 24; admitted September 4, 1864. Chronic diarrhœa of six months' standing. Has from five to eight passages daily; they are thin, watery, and very light colored. There is no record of his treatment until September 16th, when solution of bromine was prescribed. September 20th: Had but two operations in the past twenty-four hours; they are still unchanged in character. September 26th: Is much better. To have full diet. September 28th: Discharged cured.

CASE 32.—Private Joseph Chitwood, company H, 1st Georgia; admitted September 5, 1864. Acute diarrhœa. Had from eight to ten thin, watery operations in the twenty-four hours. Is very much emaciated. Was put on the use of bromine September 16th. There is no record of his previous treatment. September 22d: The patient has improved rapidly. The stools are less frequent and more natural. September 25th: Has continued to improve. The operations are now quite natural. Has been on full diet for three days. Discharged cured. [According to the hospital register this man was readmitted, with diarrhœa, October 27th, and returned to the barracks December 3d.]

CASE 33.—Private Jesse G. Ingram, company G, 48th Tennessee; admitted September 6, 1864. Acute dysentery. Had ten to twelve small, painful, bloody stools daily. Up to the 16th of September the patient did not improve. He was then put on solution of bromine. September 20th: Has improved quite rapidly; the stools are natural in appearance. September 26th: Returned to the barracks cured.

CASE 34.—Private Richard Forrest, company I, 9th Louisiana cavalry; age 25; admitted September 9, 1864. Chronic diarrhœa of five months' standing. At the time of admission he had from twelve to fifteen operations daily. The stools were light colored, thin, and watery. Was placed at once on solution of bromine. September 21st: Improved rapidly on the bromine. Had but two operations in the last twenty-four hours, and these were more natural in appearance than any he has had for months. October 9th: Continues to improve. Has scorbutic sore mouth, which should have been previously mentioned. November 5th: To take twenty drops of tincture of the chloride of iron three times daily, and to use a mouth-wash of two grains and a half of sulphate of zinc to the ounce of water. December 8th: Returned to the barracks well.

CASE 35.—Private D. K. McClinton, company C, 3d Alabama; admitted September 9, 1864. Acute dysentery. Had from eight to twelve small, bloody operations daily, accompanied by much pain. ℞. Sulphate of magnesia two drachms, opium five grains; make five powders; take one every four hours. September 12th, rest. September 13th: Repeat the prescription of the 9th. September 14th to 16th, rest. September 17th: To take solution of bromine. September 19th: Discharged cured.

CASE 36.—Private Thomas Pugh, company G, 36th Alabama; age 20; admitted September 11, 1864. Chronic diarrhœa of six months' standing. The patient has been under medical treatment most of the time, but without benefit. When admitted he had from eight to ten thin, watery, light-colored operations daily; sometimes they were streaked with blood. This man was put on the bromine treatment September 16th. September 30th: He has improved very much; the stools are more natural and less frequent. October 9th: The bowels are regular and the stools quite natural; has been on full diet several days. October 24th: Returned to the barracks cured. [According to the hospital register this man was readmitted with the same disease November 2d, and returned to the barracks November 23d.]

CASE 37.—Joseph Hammil, a conscript; admitted September 13, 1864. Acute dysentery. The stools were small, very frequent, and painful; they were chiefly composed of blood. The patient improved rapidly, and was discharged, cured, September 13th. [According to the hospital register this man was returned to the barracks September 26th.]

CASE 38.—Corporal James L. Hallsup, company L, 41st Mississippi; age 34; admitted September 13, 1864. Acute dysentery. First seen by the reporter September 24th. He had been sick five days. When first admitted had two or three stools

hourly; they were very small, painful, and chiefly composed of blood. October 1st: Is much better; has about five operations daily, but they are not painful, and contain no blood. October 9th: Discharged cured.

CASE 39.—Private John W. Basford, company I, 4th Florida; admitted September 13, 1864. Acute dysentery. The stools were small, bloody, and frequent. To take a drachm of bromine solution every two hours. The patient improved rapidly; was put on a full diet September 25th, and returned to the barracks, cured, October 1st.

CASE 40.—Private Washington H. Franklin, company H, 16th Georgia; admitted September 14, 1864. Acute diarrhœa. The patient had from eight to ten thin, watery passages daily, which were accompanied by some pain. Treatment, a drachm of solution of bromine every two hours. Returned to the barracks, cured, September 19th.

CASE 41.—Private Thomas O'Neil, company G, 2d Arkansas cavalry; age 19; admitted September 14, 1864. Diarrhœa of five months' standing. Has been under medical treatment most of the time, but without relief. Has now daily from six to eight small, painful stools mixed with blood. Treatment, a drachm of bromine solution every hour. September 23d: Is very much improved. Had but two stools in the last twenty-four hours, and these were quite natural in appearance and unaccompanied by pain. Is still weak and emaciated. October 9th: Since the last report the patient has improved very much; his bowels are regular and the stools natural. Is on full diet. October 24th: Returned to the barracks cured. [According to the hospital register this man was readmitted with diarrhœa November 1st, and returned to the barracks November 26th.]

CASE 42.—Private Francis Hopewell, company B, 1st Kentucky; admitted September 14, 1864. Diarrhœa of nearly three months' standing. Has from six to eight operations in the twenty-four hours. To take a drachm of solution of bromine every two hours. October 9th: Is very much better; the stools are quite natural in appearance. October 22d: Substituted ten drops of solution of iodine, two grains to the ounce, three times a day. November 1st and 2d, rest. November 3d to 14th, solution of iodine as before. November 15th, solution of bromine. November 20th, half an ounce of castor oil. November 21st, resume the bromine. December 1st, add a pint of milk-punch daily. December 6th: Transferred to the convalescent ward. Returned to the barracks December 11th.

CASE 43.—Private William A. Simmonton, company E, 8th Virginia cavalry; age 21; admitted September 17, 1864. Acute dysentery. Says he was sick fourteen days before admission. Has one or two very small, painful, bloody stools every hour. Treatment, solution of bromine. September 22d: Had but one operation in the last twenty-four hours; the passage was small and composed of mucus. Has had no natural evacuation as yet. After this date, however, the patient improved rapidly, and was discharged, cured, September 30th.

CASE 44.—Private Eli B. Pitts, company C, 18th Alabama; age 42; admitted September 18, 1864. Chronic diarrhœa of six months' duration. Has, on an average, six thin, watery operations daily; sometimes the stools contain blood. Treatment, solution of bromine. September 20th: Is improving; had only three operations in the last twenty-four hours; these were light colored, contained no blood, and were accompanied by very little pain. October 9th: Discharged, cured. [According to the hospital register this man was readmitted October 25th with the same disease, and died October 30th. No autopsy.]

CASE 45.—Private Samuel Yates, company C, 28th Tennessee; admitted September 19, 1864. Acute dysentery. Had been sick with dysentery five days when admitted. Had previously suffered with scurvy, and is very much emaciated; stools very frequent. Treatment, solution of bromine. September 30th: The patient has improved rapidly since the last note. His bowels are now regular and the operations nearly natural in character. October 9th: The scorbutic symptoms have almost disappeared; the passages from the bowels are quite natural in appearance and frequency. October 18th: Returned to the barracks cured. [According to the hospital register this man was readmitted with diarrhœa October 24th, and was returned to the barracks May 26, 1865.]

CASE 46.—Private Edward Lesser, company A, 11th Arkansas cavalry; age 21; admitted September 19, 1864. Chronic diarrhœa. This man was attacked with measles May 1, 1864; diarrhœa set in during the attack and has continued ever since. The patient also had a cough, with pain in the left side of the chest, and rather scanty mucous expectoration. In July he had pneumonia of the left lung, and in September an attack of erysipelas of the face. He was treated with a drachm of bromine solution every four hours until October 24th. From November 1st to 5th he had ten drops of iodine solution, two grains to the ounce, three times daily. From November 6th to 12th, kept at rest without medicine. November 14th: The bromine mixture was resumed, and November 18th, cod-liver oil and whiskey were added. November 28th: Returned to the barracks cured.

CASE 47.—Private Alfred A. Farr, company D, 7th Mississippi; admitted September 20, 1864. Acute dysentery. The patient was very weak, and had small, bloody stools almost every hour. Treatment, solution of bromine. September 30th: Is very much better; has now but two or three stools daily, and they are quite natural in appearance. Is on full diet. October 22d: Substituted for the bromine ten drops of solution of iodine, two grains to the ounce, three times daily. November 28th: Returned to the barracks cured.

CASE 48.—Private Nathan Elliott, company D, 45th Tennessee; admitted September 21, 1864. Acute dysentery. Had one or two small, bloody passages every hour, accompanied by much pain. Treatment, solution of bromine. The patient improved rapidly, and was discharged, cured, October 7th. He had been on full diet several days before he was discharged.

CASE 49.—Private William A. Steele, 20th Tennessee; admitted September 21, 1864. Acute dysentery. Had from twelve to fifteen very small, bloody stools in the twenty-four hours. Treatment, a drachm of solution of bromine every two hours. The patient improved rapidly, and was returned to the barracks, cured, September 26th.

CASE 50.—Private Cincinnatus Livingston, company E, 34th Alabama; age 22; sober; admitted September 21, 1864. Chronic diarrhœa of a year's standing. The discharges are frequent but not very painful. The patient has had spasms,

followed by periods of mental aberration. September 26th: Ordered a drachm of the bromine solution every hour. September 30th: The patient is improving slowly; his countenance has a silly expression. October 10th: The passages average twelve to fourteen daily; they are thin but not painful. The patient suffers with sick stomach; his appetite is not good. October 22d: Bowels still loose. November 12th: Returned to the barracks cured. [According to the hospital register this man was not returned to the barracks till December 25th.]

CASE 51.—Sergeant William Murray, company A, 64th North Carolina; aged 30; sober; admitted September 21, 1864. Chronic diarrhœa of a year's standing. September 26th: Bromine solution was prescribed, under the influence of which the passages became less frequent, but continued painful. September 30th: Complains of dysuria. To take a teaspoonful of fluid extract of buchu three times daily. October 30th: Passages average eleven daily, are bloody and slimy, at times painful. Has not improved as yet. Complains of pain in the small of the back and left side. Appetite not very good. November 12th: Returned to the barracks cured. [According to the hospital register this man died of chronic diarrhœa January 18, 1865.]

CASE 52.—Private John Adams, company C, 53d Georgia; age 32; admitted September 22, 1864. Chronic diarrhœa of six months' standing. The patient had been under medical treatment most of the time. On the 15th of September an acute attack of dysentery supervened. When admitted he was very much emaciated, and had small, bloody stools every hour. Treatment, bromine solution. October 1st: Has improved very much. The stools are less frequent, more natural, and contain no blood. The patient subsequently continued to improve; slowly gained strength; his bowels continued regular, and he was transferred to the convalescent ward December 13th. [Returned to the barracks December 25th.]

CASE 53.—Private Benjamin M. Day, company K, 31st Alabama; aged 20; admitted September 23, 1864. Acute dysentery. Had been sick three weeks. Stools from six to eight daily; they were small, very painful, and mixed with blood, some of them were composed entirely of blood. Treatment, solution of bromine. October 1st: Has improved rapidly; is now on full diet. October 30th: Discharged cured.

CASE 54.—Private Henry Branch, company E, 1st Alabama cavalry; age 24; sober; admitted September 23, 1864. Chronic diarrhœa of several years' standing. His last attack was in July. September 26th: Bromine solution was prescribed, under the use of which the passages became less frequent, but continued to have a mucous character, and were very painful. September 30th: Is improving slowly. October 10th: The passages average one a day and are natural in character. The patient says he feels better than he has done for the last three months, but has a cough which troubles him somewhat. October 15th: Returned to the barracks quite well.

CASE 55.—Private William I. Taylor, company B, 24th Mississippi; age 35; sober; admitted September 24, 1864. Chronic diarrhœa of two years' standing. The passages were slimy and averaged one an hour. He was treated with a drachm of the bromine solution every hour. September 30th: Doing very well. October 10th: The passages are painful, and average six to the twenty-four hours; still the patient considers himself better than when admitted. October 22d: Bowels better, but has a troublesome cough. November 3d: Discharged cured. [According to the hospital register this man was readmitted with diarrhœa December 6th, and remained in hospital until he was exchanged, February 15, 1865.]

CASE 56.—Private Philip Whitehead, Foster's Alabama battery; age 21; sober; admitted September 24, 1864. Chronic diarrhœa of eight months' standing. The stools were bloody and slimy. To take a teaspoonful of bromine solution every hour. September 30th: Is improving slowly. October 10th: The passages still average ten daily, are very painful, and contain blood and slime. The patient has a cold, and complains of sick stomach every morning. October 22d: Bowels better, some colicky pains. October 30th: Returned to the barracks well. [According to the hospital register this man died of chronic dysentery December 13th.]

CASE 57.—Private John Stevens, company I, 24th Tennessee; admitted September 24, 1864. Chronic dirrrhœa of nearly a year's standing; also suffering from a cold in the chest. To take a drachm of solution of bromine every hour. There was at first no alteration in the number of passages, which continued painful and unnatural; but the bromine was thought by the patient to relieve his chest symptoms. September 30th: Feels better; is now on half diet. Discharged, cured, October 10th.

CASE 58.—Private N. Manly, company B, 2d battalion Missouri cavalry; age 21; of dissipated habits; admitted September 24, 1864. Chronic diarrhœa of two years' standing. The last attack commenced in the early part of August. The patient is weak, has no appetite, and is also suffering from a bronchial affection. To take a drachm of the bromine solution every hour. October 10th: The passages are less frequent, rarely painful; they average seven or eight daily. The stools are viscous, but improved in appearance. The patient suffers from intense headache, is very restless at night, complains of a nauseous taste and odor of phlegm. The cramps in the stomach have disappeared, but he has pain in the right side and spine, dull pain and a sense of oppression in the chest. October 22d: The bowels are still loose, but the general health is better. October 25th: Discharged cured. [According to the hospital register this man was not returned to the barracks until November 2d.]

CASE 59.—Private James Meigs, company I, 2d Georgia cavalry; age 29; sober; admitted September 26, 1864. Chronic diarrhœa and bronchitis, from which he has suffered since last June. Under the bromine treatment the stools became less frequent and less painful, but the pains in the chest more severe. September 30th: Is very weak. October 10th: The stools are more natural, not so painful, and average three a day. The cough is quite troublesome; the patient expectorates a good deal, is restless at night, and complains of pain in his chest and stomach. October 22d: The diarrhœa is worse; the mouth presents signs of scurvy, the sputa contain blood. November 12th: Returned to the barracks cured. [According to the hospital register this man died of diarrhœa November 2d.]

CASE 60.—Private Pleasant D. Phillips, company I, 3d Confederate cavalry; age 18; temperate; admitted September 26, 1864. Chronic diarrhœa of six months' standing. The passages are thin, painful, and average eight to the twenty-four

hours. Treatment, a drachm of bromine solution every hour. October 22d: Bowels better; the patient has a severe cough. November 1st: Discharged cured. [According to the hospital register this man was readmitted with diarrhœa November 20th, and remained in hospital until he was exchanged, March 12, 1865.]

CASE 61.—Private Jesse Roberts, company I, 1st Georgia cavalry; admitted September 26, 1864. Chronic diarrhœa. This man was also suffering from a wound in the head. He had frequent and painful passages from the bowels, but his appetite was good. Under the bromine treatment the diarrhœa rapidly subsided, and, October 5th he was discharged perfectly well, so far as his bowels were concerned; his head, however, still troubled him.

CASE 62.—Private R. Nelson, company C, 27th Mississippi; a man of rather intemperate habits; admitted September 26, 1864. Chronic diarrhœa of two years' standing. The stools were bloody, slimy, and averaged one an hour. The patient is also troubled somewhat with piles. Appetite good. To take a drachm of solution of bromine every hour. September 30th: Is better; half diet. Discharged, cured, October 5th.

CASE 63.—Private E. L. Smith, company F, 4th Alabama cavalry; age 36; sober; admitted September 27, 1864. Chronic diarrhœa of a year's standing. Last attack in the spring of the present year. Stools thin and frequent. Treated with the bromine solution. October 10th: The passages average six daily; they are thin, light-colored, at times mixed with mucus, and about as painful as when he was first admitted. He complains of pain in the lower extremities. October 22d: Is better. November 12th: Returned to the barracks cured. [According to the hospital register this man was not returned to the barracks till January 1, 1865.]

CASE 64.—Private Miles J. Covington, Allison's battery; age 37; sober; admitted September 27, 1864. Chronic diarrhœa of two years' standing. His last attack was seven months ago. The passages are frequent and painful. Treatment, solution of bromine. October 10th: The passages average six in the twenty-four hours; they are less painful than when admitted. He considers himself improving. Complains of a constant pain in the small of the back. October 22d: Bowels better. November 3d: Returned to the barracks cured.

CASE 65.—Private William C. Dodson, company D, 51st Alabama; age 18; admitted September 28, 1864. Chronic diarrhœa. This man had small-pox last February, and while convalescing diarrhœa set in, accompanied by cough, with free muco-purulent expectoration, and pain in the right side of the chest during full inspiration. The diarrhœa was soon checked, but returned about a month later, and persisted. The bronchial symptoms also continued to grow worse, and when admitted the patient had profuse night-sweats. The patient was treated with the bromine solution until October 30th, when the following was substituted: ℞. Iodine two grains, iodide of potassium a sufficient quantity, water an ounce. Take ten drops three times a day. November 5th: In addition to the above, cod-liver oil and whiskey were prescribed. November 25th: Twenty grains of quinine were given. November 27th: Ordered a drachm of the bromine mixture every two hours. The cod-liver oil and whiskey to be continued. January 1, 1865: Returned to barracks cured.

CASE 66.—Private Nathan Leeson, company A, 19th Virginia; admitted September 28, 1864. Acute dysentery. At the time of admission the patient had from twelve to fifteen very small, bloody stools daily. Treatment, solution of bromine. The patient improved rapidly, and in five days was convalescent. He was put on full diet October 4th, and discharged, cured, October 9th.

CASE 67.—Private John C. Blakney, company C, 40th Alabama; age 22; admitted September 28, 1864. Chronic dysentery. Has been sick for the past six weeks. The operations are frequent, sometimes twelve to fifteen daily; they are very small, and chiefly composed of blood. Treatment, solution of bromine. The patient improved rapidly, and was discharged, cured, October 5th.

CASE 68.—Corporal Samuel Smoot, company G, 31st Alabama; age 20; admitted September 29, 1864. Acute dysentery. Had operations every hour; they were small, painful, and composed chiefly of blood. Treatment, solution of bromine. October 5th: Is very much better. Has three or four passages daily; they are still small and thin, but contain no blood, and are not painful. October 9th: The patient has continued to improve; his bowels are regular and the passages natural. Is on full diet and quite convalescent. [According to the hospital register this man was returned to the barracks November 8th.]

CASE 69.—Private Joseph H. Hagans, company E, 1st Florida cavalry; age 23; admitted October 2, 1864. Acute dysentery. The patient had small painful stools nearly every hour; they were composed chiefly of blood. Treatment, solution of bromine. He immediately commenced improving; was put on full diet October 12th, and discharged, cured, October 16th.

CASE 70.—Private Anderson Edwards, company G, 3d Florida; admitted October 10, 1864. Acute dysentery. Has small, bloody, and very painful stools every hour. Treatment, solution of bromine. Improved very rapidly, and was discharged, cured, October 17th.

CASE 71.—Artemus T. Langston; admitted October 10, 1864. Acute dysentery. Had from ten to twelve operations daily; the stools were small, painful, and streaked with blood. Treatment, solution of bromine. The patient improved rapidly, and was discharged, cured, October 15th.

CASE 72.—Private Francis B. Murphy, company E, 62d Virginia; admitted October 10, 1864. Acute dysentery. Says he has been sick five days. The stools are small, bloody, and very frequent; they are accompanied with considerable pain. Treatment, solution of bromine. The patient improved rapidly, and was discharged, cured, October 17th.

CASE 73.—Private Henry Beamer, company F, 3d Confederate cavalry; admitted October 11, 1864. Acute diarrhœa. Had been sick eight days. His bowels were moved from eight to ten times a day. The stools were tolerably large, thin,

watery, and sometimes streaked with blood. Treatment, solution of bromine. The patient improved rapidly, was put on full diet October 16th, and was discharged, cured, October 20th.

CASE 74.—Private Thomas King, company L, 56th Alabama; temperate; admitted October 22, 1864. Chronic diarrhœa. This man had long suffered from intermittent fever every fall, and was troubled with indigestion at intervals. He has had diarrhœa since last June, alternating with spells of constipation. To take ten drops of iodine solution, two grains to the ounce, three times daily. October 24th: Half an ounce of castor oil. October 25th and 26th: Rest. October 27th: Half an ounce of castor oil. October 28th to November 4th: Rest. November 5th: An ounce of castor oil. November 6th to 13th: Rest. November 14th: A drachm of solution of bromine every two hours. November 26th: Returned to barracks.

CASE 75.—Private C. Wilkins White, company G, 13th Louisiana; temperate; admitted November 1, 1864. Chronic diarrhœa. The attack commenced June 25th as dysentery, with small, frequent stools, accompanied by tenesmus, and passed into a chronic diarrhœa, which has persisted ever since in spite of treatment. November 13th: To take ten drops of iodine solution, two grains to the ounce, three times daily. November 14th: To take a drachm of solution of bromine every two hours, and a pint of ale daily. November 22d: Substituted milk-punch for the ale. November 28th: Returned to the barracks cured. [According to the hospital register this man was readmitted December 20th with the same disease, and returned to the barracks February 9, 1865.]

Fatal Cases.

CASE 76.—John G. Jones, citizen of Georgia; age 60; admitted June 4, 1864. Chronic diarrhœa. The patient was much debilitated and his left hand was paralyzed. The passages averaged one to the hour; the abdomen was painful, no appetite. There is no record of his treatment until he was put upon the solution of bromine in September. September 29th: Is very weak; the flux continues unchecked. September 30th: The passages are small and bloody; complains of sick stomach. Died October 1st. No autopsy. Acting Assistant Surgeon H. F. Gilbert.

CASE 77.—Private J. W. Nelson, company E, Herald's Arkansas battalion; temperate; admitted July 23, 1864. Diarrhœa of six months' standing. First seen by the reporter September 26th. The passages are painful and average one every hour; the stools are mucous; the legs and feet are œdematous and painful; the patient has no power over them. The patient labors under enthusiastic hallucinations. He has no appetite and is very much debilitated. He was attacked yesterday with a pain in the left side of the chest, which is more severe to-day. Treatment, a drachm of the solution of bromine every hour. Died October 2d. No autopsy. Acting Assistant Surgeon H. F. Gilbert.

CASE 78.—Private William Baily, company B, 2d Kentucky cavalry. Died October 19th. [A full account of the autopsy in this case is given by Acting Assistant Surgeon H. F. Gilbert in his report on the use of bromine, *supra*, p. 52.]

CASE 79.—Private James Turner, company B, 63d Virginia; age 33; admitted August 26, 1864. Chronic diarrhœa. Has been sick about twelve months, most of the time under medical treatment, but never free from diarrhœa more than a week at a time. Was treated with pills of nitrate of silver and opium, &c., until September 14th, when solution of bromine was prescribed. At this time he had frequent stools, which were small, nearly white, and sometimes streaked with blood; they were attended with a good deal of pain. September 21st: Substituted ten drops of iodine solution, two grains to the ounce, three times a day. October 9th: The patient has taken cold and had a relapse. The stools are again frequent, but not so thin as at first, and natural in color. November 13th: The diarrhœa still continues; resumed the solution of bromine. November 20th: The chest symptoms becoming severe, a blister five inches by six was applied to the left side of the chest. November 30th: To have a pint of milk-punch daily. Continue the bromine. December 9th: Continue treatment, and add the following: ℞. Sulphate of quinia twenty grains, opium five grains. Make five powders. Take one every four hours. December 10th: Repeat the quinine. December 11th: Cod-liver oil and whiskey; also enemata of ten drops of bromine to the ounce of water. Ten grains of Dover's powder at night. Died December 15th. *Autopsy* twenty hours after death: The left pleural cavity contained about a pint of bloody serum, in which a few flakes of lymph floated. The left lung was adherent to the thoracic parietes anteriorly, and infiltrated with tubercles, which in many places were softened and broken down; the parenchyma between them was much congested. The right lung was somewhat congested anteriorly, but otherwise healthy. The liver presented the nutmeg appearance. The stomach was normal. The intestines were apparently healthy, with the exception of the rectum, the mucous membrane of which was studded with chronic ulcers, some of which appeared to be healing; between them were puckered cicatrices of various dimensions, the largest the size of a five-cent piece. The mesenteric glands were enlarged. The other organs were healthy. Acting Assistant Surgeon H. F. Gilbert.

CASE 80.—Private George McDaniel, company G, 40th Alabama; age 45; admitted September 24, 1864. Chronic diarrhœa. The patient stated that he had been under treatment for this disease about fifteen months. He is very much emaciated; his skin dry and yellow; his tongue coated but somewhat moist. The stools are frequent, small, and muco-purulent; they are accompanied by griping and tenesmus. His feet and legs are œdematous, and so painful that he is unable to rest at night. Has some cough, with a white, tough, frothy mucous expectoration, and sibilant rales are heard over the entire chest. His stomach is irritable and he vomits frequently. Has no appetite for food, and will take only a small quantity of soup or beef-tea. To take a teaspoonful of bromine solution every three hours, and a warm bath. Under this treatment the pain ceased, the discharges became quite consistent, diminished in frequency, and there was some improvement in appetite. October 15th: The supply of bromine being exhausted, a solution of iodine was substituted. October 22d: The stools consist of bloody mucus; the pains have recurred with severity; the patient seems very weak. To take a Dover's powder at night. Milk-punch, beef-tea. October 30th: Continues to decline; complains of want of sleep and of a sense of suffocation; pulse very feeble and irregular. Died November 4th. For two days before his death he had been very dull and stupid. *Autopsy* twenty-

four hours after death: Body greatly emaciated. The pericardium contained eight ounces of serum. The heart was small and somewhat fatty. The left lung was adherent throughout; its posterior lobe was hepatized. The right pleural cavity contained about three pints of dirty fetid fluid. The right lung was crepitant throughout, but contained a few tubercles, which were black with pigment deposit. The abdominal cavity contained about two gallons of transparent fluid. The liver was apparently normal. The gall-bladder contained nine calculi. The stomach was normal. The large intestine was much thickened, and its mucous membrane was ulcerated. The kidneys were smooth and pale. Acting Assistant Surgeon H. F. Gilbert.

CASE 81.—Private Peter R. Green, company H, 9th Georgia; admitted December 14, 1864. Chronic diarrhœa. This man was captured at Knoxville, Tennessee, December 5, 1863; arrived at this post January 6, 1864. Was taken sick January 13th, since which time he has not been well. Has been sent from the barracks to hospital several times. When first seen by the reporter, January 17, 1865, his pulse was 90 and feeble; he was extremely emaciated; tongue coated white. He had been treated by Dr. Gilbert with bromine for the last six days, during the last three of which he had no passage from the bowels. He complained greatly of abdominal pain. A tablespoonful of castor oil was, therefore, administered, which operated promptly. The stools were purulent. Subsequently pills of assafœtida and morphia were prescribed, with milk-punch and nourishing diet. He died January 31st. *Autopsy* eight hours after death: The pericardium contained between ten and twelve ounces of fluid. Both lungs were firmly adherent to the thoracic parietes and contained tubercles at their apices. The spleen was large and engorged with blood. The mucous membrane of the large intestine was in a gangrenous condition. Acting Assistant Surgeon H. F. Salter.

CASE 82.—Private Edward Gilliom, company H, Wright's Arkansas battalion; admitted January 3, 1865. Chronic diarrhœa. The patient was under Dr. Gilbert's charge, and was treated with bromine solution and an occasional Dover's powder until January 16th, when he came under the care of the reporter. He was then very much emaciated, and had frequent purulent discharges, accompanied with pain and tenderness on pressure upon the lower part of the abdomen. He was subsequently treated with pills of nitrate of silver and opium, enemata of acetate of lead and starch-water, mercury with chalk and opium, &c. He died January 23d. *Autopsy:* The lungs, heart, liver, and spleen were healthy. The peritoneum generally was congested. The mucous membrane of the intestines was also congested. In the rectum the mucous membrane was gangrenous. Acting Assistant Surgeon H. F. Salter.

CASE 83.—Private John R. Fisher, company E, 1st Florida; admitted January 13, 1865. Chronic diarrhœa. This man was taken prisoner November 25, 1863. He was attacked with diarrhœa about the middle of March, 1864, and has been troubled with it ever since. When admitted he was greatly emaciated, and had from seven to nine light-yellow, watery stools daily; his tongue was red and glazed, and his throat was sore; his pulse was 90 and small. This patient was treated by Dr. Gilbert with bromine until the 17th of January, when the reporter substituted creasote mixture and enemata containing acetate of lead. He was subsequently treated with pills of nitrate of silver and opium, acetate of lead and opium, &c., without benefit. Died February 2d. *Autopsy:* The lungs contained an excess of black pigment, otherwise the thoracic viscera were normal. The large intestine was highly congested and ulcerated, the rectum gangrenous. The mesenteric glands were much enlarged. Acting Assistant Surgeon H. F. Salter.

CASE 84.—Private Joseph Laflat, company H, Thompson's regiment; admitted January 19, 1865. Chronic diarrhœa of over two months' standing. When admitted the patient was extremely emaciated, the stools were painful, the abdomen tender, the tongue coated, the countenance shrunken, the pulse 90 and full, the skin dry and harsh. Five grains of blue mass and a grain of opium were administered, and this was followed by a drachm of solution of bromine every two hours. This was continued until January 23d, without any improvement taking place. Subsequently pills of rhubarb, tannin, and opium, &c., were employed with temporary benefit. The stools were reduced in number to two a day, and appeared to be natural in character. January 31st, however, the diarrhœa recurred, accompanied by severe pain in the side, and the patient died during the night. *Autopsy* next day: The lower lobe of the left lung was hepatized. The pericardium contained four ounces of fluid. The liver was healthy. The spleen was about twice its natural size. There was an intussusception in the small intestine. The descending colon and rectum were extensively ulcerated. The mesenteric glands were enlarged. Acting Assistant Surgeon H. F. Salter.

CASE 85.—Private Robert Hunter, Hodge's Missouri regiment; age 24; admitted January 21, 1865. Chronic diarrhœa. In this case the disease began with an attack of acute dysentery following a cold; this passed into chronic diarrhœa. When admitted the patient had no appetite; complained of nausea and pain in the bowels. The stools were slimy and frequent, the pulse 90 and soft; micturition was painful. To take a drachm of solution of bromine every three hours. This was continued for three days without benefit, when turpentine emulsion was substituted. Subsequently acetate of lead and opium, Hope's camphor-mixture, creasote mixture, &c., were employed. Died February 1st. *Autopsy* the same day: The lungs were tubercular. The pericardium contained six ounces of serum. The liver, spleen, and kidneys were healthy. The mucous membrane of the small intestine was congested and softened. The descending colon and rectum were very much thickened and ulcerated. Acting Assistant Surgeon H. F. Salter.

CASE 86.—Robert Pritchet, Missouri conscript; age 18; admitted February 3, 1865. Diarrhœa. This man, who was of intemperate habits, was first taken sick with diarrhœa about Christmas, 1864. When admitted he was already much emaciated; his pulse was 80 and soft; his tongue coated. He had severe pain in the head, great thirst, and no appetite. The operations from the bowels ranged from fourteen to sixteen in the twenty-four hours; they were light-yellow and watery. He complained of pain in the chest, and had a cough, with difficult respiration. He was treated with bromine mixture, quinia, and milk-punch. February 5th: Is no better. Applied mustard plasters to chest and abdomen, and ordered enemata of sugar of lead and laudanum. Died February 6th. *Autopsy:* The pericardium contained about ten ounces of fluid. A large clot was found in the

right auricle of the heart. The right lung was completely hepatized, the left much congested. The liver was healthy; the gall-bladder distended with bile. The spleen was congested. There was an intussusception of the small intestine about eight inches long. The large intestine was highly congested and slightly ulcerated. Acting Assistant Surgeon H. F. Salter.

CASE 87.—Private William A. Burke, company G, 31st Alabama; admitted October 4, 1864. Chronic diarrhœa. Has been sick since November last. Was first seen by the reporter October 11th. To take ten drops of iodine solution, a grain to the ounce, three times a day. October 14th: A drachm of solution of bromine every two hours. October 15th: Add to the above fifteen grains of chlorate of potash three times daily. This treatment was continued till October 31st, when cod-liver oil was prescribed in addition. December 11th: The bromine solution was continued, and twenty drops of the tincture of the chloride of iron, three times daily, substituted for the other remedies. Acting Assistant Surgeon H. F. Gilbert.

January 1, 1865, Acting Assistant Surgeon W. Mathews took charge of the ward and found the patient suffering with fever, chills, and excessive termina in addition to the ordinary symptoms of diarrhœa; he prescribed a solution of quinine and morphia. Died January 6th. *Autopsy* ten hours after death: There were extensive pleuritic adhesions on the right side, and numerous melanotic patches on the surface of both lungs. The liver and spleen were small and pale. The gall-bladder was greatly distended with a dark, gelatinous fluid. The descending colon and rectum were extensively ulcerated; the rectum so much so that it tore when handled in the gentlest manner. No other abnormities were observed.

CASE 88.—Private William J. Nichols, company E, 19th Alabama; age 27; admitted June 23, 1864. Chronic diarrhœa. This man was first seen by the reporter about November 25th. He was then very ill. He was treated with solution of bromine, and seemed to be getting along tolerably well until December 24th, when he was taken suddenly worse, and died December 25th. *Autopsy* four hours after death: There were extensive tubercular deposits in both lungs. The heart was normal. The mesentery was congested and the mesenteric glands much enlarged. The mucous membrane of the intestines was very much diseased, especially that of the large intestine and rectum. Indurated spots and cicatrices were numerous in the small intestines. Acting Assistant Surgeon J. B. Young.

CASE 89.—Private Allen T. Stott, company F, 5th Kentucky; age 49; admitted November 26, 1864. Chronic diarrhœa. This man was transferred to Rock Island barracks June 27th. Shortly after, he had an attack of erysipelas, which was treated in this hospital. He states that he has been troubled with diarrhœa ever since. When admitted he did not appear to be very sick, but he gradually grew worse, and died January 31, 1865. During the first few weeks after admission he was treated with bromine, but growing worse, salines in small doses, with opium, were substituted; stimulants and tonics were also employed. *Autopsy* twelve hours after death: There were firm, old adhesions on the right side, and some evidences of recent pleurisy on both sides. The right cavities of the heart contained large fibrinous clots. The liver and spleen were congested and softened. The mucous membrane of the large intestines was softened, ulcerated, and in places gangrenous, the descending colon and rectum being most diseased; the ulcers in many places had penetrated to the peritoneum. The mesenteric glands were enlarged. Acting Assistant Surgeon J. B. Young.

CASE 90.—Private David Chapman, company E, 16th South Carolina; age 20; admitted November 27, 1864. Diarrhœa and consumption. This man had been in hospital twice before. He was much emaciated and dispirited; had considerable cough and pain in the chest. The diarrhœa was very troublesome, his bowels being moved from ten to twenty times daily. His pulse was quick and feeble; tongue dry and narrow. He was treated with bromine, iodide of potassium and opium, muriate of ammonia, Dover's powder, &c. Had wine and whiskey as stimulants. Died February 1, 1865. *Autopsy* six hours after death: Both lungs were full of tubercles and contained numerous vomicæ; the right lung was most diseased. The heart was normal and contained a large fibrinous clot. The liver was adherent to the diaphragm, congested, and softened. The spleen was shrunken. The mesenteric glands were enlarged. The omentum was shrunken and congested. The mucous membrane of the large intestine was thickened and softened. The lower portion of the colon and rectum were extensively ulcerated. Acting Assistant Surgeon J. B. Young.

CASE 91.—Samuel D. Smart, Government employé; age 36; admitted December 17, 1864. Chronic diarrhœa. When admitted this man had a frequent, feeble pulse; his tongue was dry and brown, his surface cold and blue. He complained of dyspnœa and was anxious and restless. Treatment, bromine, opiates, &c. Died December 25th. *Autopsy* twelve hours after death: There were extensive pleuritic adhesions on both sides, and tubercles at the apices of both lungs. Some effused serum was found in the pericardium, and a considerable quantity in the peritoneal cavity. The large intestine was extensively ulcerated. The mesenteric glands were enlarged. Acting Assistant Surgeon J. B. Young.

Extract from a letter by Surgeon MORSE K. TAYLOR, U. S. Volunteers. *Keokuk hospital, Iowa, September* 9, 1864.

* * * In those cases in which the disease is purely diarrhœa, and a morbid condition of the bowels is confined to the small intestines, viz: the ileum, and occasionally the jejunum, there have been no ulcerations of the mucous membrane present. There is vascularity, oftentimes giving rise (and I may say that it is nearly always the case) to the "mahogany appearance" mentioned by Dr. Tripler; sub-mucous infiltration and thickening of the mucous membrane, such as we sometimes see in chronic bronchitis; and in some cases there is softening and erosion of the epithelial surface, but never well defined as in acute inflammations or ulcerations of the same parts. Peyer's patches I have never seen involved in this disease. In one specimen I have in my possession, a Peyer's patch is surrounded by thickening, plastic effusion, vascular injection, &c., all showing a high grade of action; but the patch itself is entirely normal. This I have seen in many instances. The solitary follicles are almost invariably enlarged. The only exception to these appearances, as I have yet observed them, is in the

immediate vicinity of the ileocæcal valve, where erosions and jagged ulcers occur in almost every case when that part of the intestine is involved, which, as a general thing, is not oftener than one case in four.

When the colon is involved, however, the morbid appearances are far different, and erosions, jagged ulcers, and great vascular injection are present in all the cases coming under my notice. There is another condition of the colon which has some interesting features, namely: In diarrhœa it is always contracted, oftentimes not larger than the finger, while, when the passages are accompanied with tormina and tenesmus, the disease being dysenteric in its character, the colon has been less contracted, and in some cases considerably distended with gas in a portion of its course. When the principal disease is located in the region of the ileocæcal valve, distension is nearly always present. As I have before stated, colitis is the less common affection, and when it has occurred the symptoms have been those of chronic dysentery.

* * * More than half of the cases of cardiac disease coming under my notice belong to the right side, which is so different from what we observe in private life. I am disposed to account for this on the grounds of the great frequency of pulmonary diseases in the army, particularly pneumonia, chronic bronchitis following measles, interference with the functions of respiration by the belts and great weight borne upon the chest by the soldier, and the scorbutic condition, in which the muscular tissue is more or less enfeebled, particularly that of the heart, so that when undue labor is thrown upon it, as in heavy and rapid marchings, strong mental excitement, &c., the walls yield, and more or less permanent results follow in the way of dilatation of the right ventricle and imperfect closure of the tricuspid valves. I have only secured, as yet, three morbid specimens, while I have examined nearly one hundred and fifty cases in all. * * *

Extract from the Report of Surgeon William M. Wright, 79th Pennsylvania Volunteers. *Thomas general field hospital, Kingston, Georgia, September* 30, 1864.

The disease which has resulted in the greatest fatality and presented the greatest difficulty of treatment at this hospital is chronic diarrhœa. In certain of its stages it is quite tractable, but in others indomitable. The cases in which a judicious course of treatment was pursued before emaciation was conspicuous generally terminated favorably; but in those cases in which emaciation had progressed and there was a retracted, hard, and tender abdomen, a dry and glazed tongue, and an altered vocal intonation, the mortality was very great. The majority of such cases exhibited evidences of a scorbutic taint. Such was the fact in a marked degree in the cases received at this hospital from the front, on the 30th of July last. Malaria existed in quite a number of them. If the hæmorrhage from the bowels was at all considerable, all modes of treatment were ineffectual. The most efficient treatment of this disease has been the administration of a mixture of nitro-muriatic acid prepared after this formula: ℞. Nitro-muriatic acid one fluid drachm, tincture of opium half a fluid ounce, compound spirits of lavender three fluid drachms, peppermint water six fluid ounces. Mix. A fluid drachm of this mixture, given every two or three hours, according to the severity of the case, produced prompt and effectual relief, which, with a carefully restricted diet, was permanent. In cases of greater gravity it was necessary to continue the mixture for some days to obtain the same results. In those cases in which extreme emaciation existed, favorable results were obtained from the internal and external use of nitrate of silver—internally in quarter-grain doses thrice daily, and applied externally over the full extent of the abdominal surface. The effects of the nitrate thus used were a cessation of the diarrhœa, a healthy appearance of the tongue, a softening of the skin, &c. A majority of these cases have terminated fatally, and apparently from inanition.

Extract from the Report of Acting Assistant Surgeon Thomas C. Mercer *to* Surgeon M. Goldsmith, U. S. Volunteers, *in charge of Jefferson hospital, Jeffersonville, Indiana, on articles of food found in the stools of patients laboring under chronic diarrhœa. March* 27, 1865.

On examination of the stools of patients laboring under chronic diarrhœa, recently received from Eastport, Mississippi, into ward 7, I have discovered the following articles of food in an undigested condition. The quantity of excrement besides the undigested matters was not large, but very liquid: Bed 36: Onions, meat, and bread-crusts—the onions in excess and, perhaps, half a pint in quantity. Bed 37: Eggs, raisins, and bread in about equal quantities; perhaps, in thirteen stools, enough to fill a pint measure. Bed 39: Onions, about half a pint in nine stools. Bed 40: Bread-crusts not properly masticated, and unaltered by retention in the stomach, not even rendered soft by the surrounding liquid; about one pint in seven stools. Bed 41: Bread-crusts, meat, and eggs, about one pint in six stools. Bed 28: Milk, pure and unaltered by its retention in the stomach and bowels, perhaps two-thirds of a pint in quantity.

The patients assured me that such had been their condition for some weeks; that whatever they ate passed undigested. Many examinations of the washings of the stools, of which the above are fair samples, have led me to believe that chronic diarrhœa, as it exists in the army, is a course of purgings kept alive by ingesta, which from the atony of the stomach and bowels is not altered by its retention, but is allowed to gravitate and move on by the liquid contents until a desire is created to void the contents, and it reaches the "stool" in the aforesaid condition.

Special Report on cases of acute dysentery occurring in the detachment of troops stationed at Columbia, South Carolina, by Assistant Surgeon Elliott Coues, U.S.A. *November* 30, 1868.

[The following report, descriptive of a number of cases of acute dysentery which occurred in the garrison at Columbia, South Carolina, in the fall of 1868, is here presented because it was similar in its character to many of the local epidemics which occurred during the war, in which, however, no autopsies were made. An abstract of the principal diseases at the post during the last six months of 1838 has been prepared from the monthly sick reports, and is appended to the report of Assistant Surgeon Coues.]

I have the honor to accompany my monthly report of sick and wounded for November with the following remarks:

With the first cold weather, which occurred in October, there was, as usual, a marked falling off in the number of cases of malarial fever; simultaneously with which a malignant and very intractable form of dysentery sprang up, which, though not to be called epidemic, has been marked by the severity that ordinarily characterizes epidemics, and differs from anything that I have before observed at this post in this and some other respects. The citizen physicians have not met with such cases in their practice. The disease is confined to the garrison, and has particularly affected company H of the eighth infantry. The hygienic conditions of the camp are good; those of company H differing in no way that I can discover. I cannot point to the immediate cause of the disease, but I think its connection with malaria as the ultimate cause is in the highest degree probable, if not demonstrable. The disease appears to result from a special localization and development of the miasmatic poison. With this endemic origin predisposing causes are presumably to be found in the general habits of life, condition of the system, &c., and exciting causes in exposure in the line of duty, imprudent irregularities, &c.; but the number of cases observed is too small to permit satisfactory statistical analysis. Details of three fatal cases, to serve as the histories of the specimens forwarded to the Museum, are given in the accompanying report. The following is a sketch of the natural history of the disease, derived from about twenty cases, the remarkable similarity of which in all essential features renders one description applicable to all:

The attack is ushered in by moderate febrile action, with pains in various parts of the body, headache, sleeplessness, loss of appetite, thirst, heavily-coated tongue, and the ordinary tormina, relieved by frequent tenesmic stools, which shortly become muco-sanguineous, the florid blood definitely streaking the frothy mucus, of which the light-colored fæces chiefly consist, after the large intestine has been emptied. The prostration of strength is not great for the first few days, and there is little to indicate more than an ordinary attack of dysentery. During this stage I have reason to believe that prompt treatment prevented further mischief in several instances; but in most cases the inflammation proceeded to further development, treatment proving scarcely palliative. The next symptom is suppression of urine, which occurred in every case at a period varying from the third to the tenth day, of a varying degree of severity, amounting in some cases to total stoppage, and liable to recur at irregular intervals during the course of the disease. This complication ordinarily yielded in a few hours to moderate doses of acetate of potash given every half hour. The hepatic functions do not appear noticeably disordered, nor to have any special relation to the disease. Mercury seems contra-indicated in most instances. Aside from the anorexia the stomach is not affected. Emesis is unusual, apparently only casual; in only one case was it continued; whenever occurring, the ejected matters are generally tinged with bile. The tongue remains persistently furred or coated for a period varying from one to two or three weeks. When it cleans off, if the patient is convalescing, it resumes a natural condition, otherwise it becomes of a uniform bright red, at first soft and moist; a change from which condition to a hard, dry, red one, accompanies each exacerbation of the disease, and is an extremely unfavorable symptom. In two of the fatal cases it was persistent to the last; in the third, the most protracted one, the tongue became covered with a hard, brown, broken crust, as in cases of typhoid fever. The teeth collected sordes in each of these cases, not in the others.

The stools change their character frequently, irregularly, and without assignable cause. The muco-sanguineous stage is of comparatively short duration, as already stated, but subsequently discharges may occur at intervals and for a varying length of time, consisting mainly of frothy, greenish mucus, accompanied by dark blood. Calomel would neither produce nor alter this condition. The discharges, in fact, do not, as a general rule, continue of a dysenteric character, rather resembling those of chronic diarrhœa, except in the presence of blood. When least frequent they are apt to be thicker, darker, and very fetid; the mucus is frequently glairy and tenacious. Toward the last, in the fatal cases, the blood increases in quantity and becomes grumous, and may be passed almost free from true fæcal matters. In one of the cases the fatal result was precipitated by a sudden profuse hæmorrhage of clear blood. Only one of the cases lingered so long that the passages became involuntary. The tormina, though constantly recurring, and at times very severe, is usually transient. The patient refers the griping to the pit of the stomach, *i. e.* to the transverse colon. Tenesmus, though frequent, is not ordinarily a prominent or very distressing symptom, for the reason, as shown by the autopsies, that the disease was most intense at the upper part of the large intestine, leaving the rectum comparatively in good order. The passages sometimes number thirty or forty in a day and night; at other times are reduced to two or three, without assignable reason; a dozen is the average. The change in number may be as sudden as it is unaccountable. Some patients are troubled more in daytime, others chiefly during the night. Paroxysms of pain and urgent calls are apt to occur about daybreak or during the two or three hours preceding. There are no indications of peritoneal inflammation, and there is no tympanites. The abdomen is flaccid and painful upon palpation, especially along the course of the colon. Occasionally palpation excites painful spasmodic action of the intestine, when the course of the cæcum and ascending colon particularly may be traced, the gut feeling like a hard-knotted cord. The accompanying fever is of a purely asthenic type, and the general condition of the patient, in the protracted cases, is that of one suffering with typhoid fever. The skin is occasionally harsh and dry, but this condition is transient, occurring only during exacerbations of other symptoms; at other times it has the natural temperature and moisture. Sudamina were not observed. The pulse varies so irregularly as to offer no satisfactory indications.

I have already mentioned the presumed and highly probable malarial origin, or at least connection, of this dysentery. The supposition is confirmed by the unmistakable signs of periodicity manifested through its course. In earlier stages the symptoms are purely intermittent; later they became remittent; still later, when the pathological conditions below described are established, periodicity is obscured or lost; but though thus masked, as it were, and overshadowed, as far as the original phase is concerned, periodicity is developed in another and highly interesting way, viz: A weekly exacerbation of the fever and other systemic symptoms, thirst, anorexia, insomnia, &c., the dysenteric symptoms remaining the same or being but slightly aggravated. This condition generally lasts for twenty-four or forty-eight hours. Although the number of my cases is so small, the length of time that most of them have been under observation assures me that I am not deceived in ascribing this tendency to exacerbation upon the seventh or eighth day. The liability to relapse, properly so called, as distinguished from tertian or weekly changes, appears imminent. Two cases, so far convalescent as to be able to be about, relapsed into their previous condition without traceable cause. The average duration of the fully developed disease cannot yet be exactly stated, but may be

considered as from six weeks to two months, so that the term chronic becomes applicable, though there is no obvious distinction, except as to time, between any of the cases in which the disease became fairly established. Not reckoning those cases that were never fully developed, the briefest case was one of two weeks' duration. The first fatal case terminated in three weeks by a sudden hæmorrhage, the other two lasted respectively five and six weeks. A number remain under treatment.

Treatment has proved to the last degree unsatisfactory. The few cases that were arrested in the beginning were apparently cured by castor oil and laudanum, followed by opium and quinia in large doses, with strict dietetic regimen and absolute rest in bed. For other cases, after trial of various agents reported remedial, I have fallen back upon the constant and free exhibition of opium combined with quinine in tonic doses, and a small quantity of nitrate of silver. Ipecacuanha in large doses excited vomiting, but appeared otherwise inert except in one case, where it seemed to do good and was consequently persevered in. Calomel gave negative results; so also did several mineral astringents. Mercury and chalk with Dover's powder, and aromatic sulphuric acid occasionally appeared to be beneficial, but their continual exhibition irritated the stomach. Brandy and laudanum, with sinapisms to the abdomen, gave temporary relief from tormina. Opiated mucilaginous injections restrained the tenesmus and diminished somewhat the frequency of the stools. Emulsion of oil of turpentine, in one case, improved the appearance of the tongue for a while. Alcoholic stimulation was clearly indicated after the first stage; brandy was the best form, whiskey the next. Tarragona wine invariably made the patient worse. I enforced every precaution in diet, allowing as little food as possible in the early stages, and that of the blandest and lightest nature. As the demand for more nourishment became evident, I gave beef-tea, chicken-broth, soft boiled eggs, and milk, especially in the form of milk-punch, in addition to the articles previously used, such as farina, corn-starch, gelatine, toasted cracker and tea, &c.

Although I do not credit the disease with being contagious, there is some reason to believe that one or two cases occurred in hospital that might not have arisen had not other cases been present. As a matter of ordinary precaution stools were always promptly removed, and vessels cleansed with chlorinated soda or solution of permanganate of potash. Bedding was changed as soon as soiled, and the wards frequently disinfected with Squibb's chlorine mixture.

Post mortem appearances account for the intractability of the disease and clearly indicate its pathology. Its restriction to the large intestine without serious interference with other organs is interesting, considering the intensity of the inflammation and the grave constitutional symptoms. The focus of the disease is at the cæcum in one direction, the inflammation stopping abruptly at the ileocæcal valve; in the other it extends, lessening in severity, to the anus. It is not extended by contiguity of tissue from the transverse colon to the stomach. The kidneys, though functionally deranged, exhibit no structural lesions. The peritoneal investment of the bowels suffers least; no inflammation is excited in the serous lining of the abdomen. Inflammation of the mucous membrane is most intense, and results, in extreme cases, in disorganization and consequent sloughing over a great part of the tract. Where the mucous membrane is not thus extensively destroyed, large circumscribed ulcers occur. In two specimens the coats of the intestine were much thickened and indurated except where the ulcers were situated. In one they were unusually thin, and very easily lacerated. The caliber of the affected tube was lessened in two cases, not so, however, in the other. Other structural lesions, needless here to particularize, are exhibited by the specimens forwarded.

CASE 92.—Private Thomas Jones, company H, 8th United States infantry; a man of full habit of body; intemperate; age about 35; admitted October 21, 1863. Acute dysentery. The patient stated that he had suffered for some time with looseness of the bowels, to which he had paid no attention until the "bloody-flux" appeared. He then had tormina, tenesmus, anorexia, insomnia, cephalalgia, violent thirst, hot, dry, harsh skin, tongue heavily coated, fifteen to twenty muco-sanguineous

* The command consisted of company E, 3d artillery, companies B and H, 5th artillery, and part of the 8th infantry.

small liquid stools daily. On the third day there was complete suppression of urine, which continued for twenty-four hours. The symptoms were modified but little during the course of the disease, except that the remitting character of the affection gave some days of comparative ease from pain, with infrequent stools, more appetite, better sleep, &c. The emaciation, though marked, was not extreme. The tongue cleaned after the third day, and became light red, soft, and moist; toward the last it became hard and dry. There was great pain on pressure along the colon, and particularly in the right iliac fossa. The patient also complained of great pain in the right hypochondrium accompanying the respiratory movements. This pain was described as a stitch. The stools changed so frequently in character and quantity that it is difficult to describe them comprehensively. Toward the last they became less mucous and more bloody; the fæcal portion was always liquid, dark and fetid, the blood mostly dark and grumous, but containing some of more florid hue. Up to a few hours before death there was no aggravation of symptoms. Death occurred suddenly, from a profuse hæmorrhage per anum, apparently of arterial blood, occurring while the patient was straining at stool. A pint or more of blood was lost. Died November 11th. *Autopsy:* The stomach and small intestine were perfectly healthy. No lesions of any organs except the liver and large intestine were observed. The liver was occupied by an enormous abscess, pointing and about to break through the diaphragm into the right pleural sac, almost pointing also below, several square inches of the under surface of the organ being soft and of a dull-green color. The intestinal tract, from the ileocæcal valve to the anus, was highly inflamed; its coats were thickened and indurated. The mucous membrane was soft, sloughing, or already disorganized and lost at certain parts. Several large ulcers were produced by the separation of the sloughs exposing the muscular coat. The lesions were most marked in the cæcum and the adjoining parts of the colon; thence extending to the rectum, but not invading the ileum. [No. 995, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the cæcum and ascending colon, which is somewhat thickened, and presents a number of extensive diphtheritic ulcers, some of which penetrate to the muscular coat. The mucous membrane between them is frosted with pseudo-membrane. The ulcers in many places communicate freely with each other, so that the intervening mucous membrane, the total area of which is rather less than that of the ulcers, appears as islands of irregular form.]

CASE 93.—Private Charles Smith, company H, 8th United States infantry; a slightly built youth; age about 21; good habits and no other organic disease; admitted October 11, 1868. Had previously suffered with malarial fever. The dysenteric symptoms were essentially the same as in the case of Private Thomas Jones, but from the greater duration of the disease the emaciation became extreme. Toward the last the passages were discharged involuntarily, and little or no blood was passed except during the forty-eight hours preceding death, when the amount of grumous blood was considerable. The tongue, after having cleaned, became covered with a hard, cracked crust. The general aspect of the patient was that of one suffering from true typhoid fever. During the five weeks of the disease there were many remissions, at first occurring every two or three days, but subsequently less frequently. The symptoms once abated so decidedly that their subsequent recurrence might almost be regarded as a true relapse after partial recovery. The pulse ranged from 120 to 140 during the last few days. Death was very gradual, and apparently from exhaustion. Died November 16th. *Autopsy:* All the organs except the large intestine were healthy. The latter was in very much the same condition of ulceration as in the case of Thomas Jones, but the walls of the colon were rather thinner than usual, instead of thicker, and very easily lacerated; the caliber of the tube was not lessened. The same restriction of the disease at the termination of the ileum was observed. The inflammation was more evenly distributed thence to the rectum. [No. 996, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the cæcum and ascending colon. In the lower half of the piece the mucous membrane presents a few minute follicular ulcers, and in some places is thinly plastered with psuedo-membrane. The mucous membrane of the upper half has been almost entirely destroyed by the separation of extensive diphtheritic sloughs, leaving an irregular ulcerated surface, in the midst of which there are several small islets of nearly normal mucous membrane. There is a considerable quantity of adipose tissue on the peritoneal surface of the gut.]

CASE 94.—Private Donald Gray, company H, 8th United States infantry; age about 40; intemperate; admitted September 12, 1868. General debility from intermittent fever and consumption. The symptoms of the latter disease were not severe. The ague disappeared under proper treatment, and the general condition of the patient improved until the dysenteric symptoms made their appearance. These were at no time so severe nor so continuous as in the cases of Smith and Jones, nor did they adequately express the highly diseased condition in which the colon was found after death. They were purely intermittent, like the original malarial disease. At times the discharges only numbered one or two in the twenty-four hours, and the patient experienced but slight pain in the abdomen; generally little or no mucus was passed, and the stools had the appearance of ordinary diarrhœal ones; but during the exacerbations, which occurred irregularly, on an average not oftener than once a week, the tormina and tenesmus were severe. At such times the tongue was sometimes furred, sometimes clean and red; the passages were quite bloody, and as many as twenty a day. This was their character during the last week of life. Vomiting of greenish mucus also accompanied the exacerbations, and was a frequent and distressing symptom. The suppression of urine was less marked than in other cases. Died November 28th. *Autopsy:* There were a few tubercles at the apex of the left lung; the upper lobe of the right lung was full of tubercles, and contained a cavity of moderate size full of mucus and pus. The heart was perfectly healthy. The liver presented a good example of the so-called drunkard's liver. The stomach was healthy, with the exception of some slight reddening of the mucous membrane, and the small intestine was also healthy, except the lower part of the ileum, which was thickened and coated with pseudo-membrane. The walls of the large intestine were enormously thickened and indurated, except part of the cæcum, which was thin and rotten, tearing readily while being removed. The mucous membrane was disorganized and had sloughed away from nearly the whole of the tract, hanging in long slimy shreds at some parts. The colon appeared to be unusually short. [No. 997, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the very much thickened cæcum and ascending colon, the mucous membrane of which has been coated with pseudo-membrane, and is in a sloughing condition; one slough, nine inches long, is still attached at one extremity, and hangs from the upper part of the piece. There is a good deal of adipose tissue on the peritoneal surface of the gut.]

Extract from a Letter by Dr. JOHN G. F. HOLSTON, late Surgeon of Volunteers and Brevet Lieutenant Colonel. *Washington, D. C., June* 7, 1870.

* * * Whenever large armies are moving in the field diarrhœa and dysentery occur, owing to the irregularity of the soldiers' diet, to exposure to cold when heated and fatigued, and to malaria. * * * The chief cause, however, seems to be malaria, or that unknown influence which causes ague and is counteracted by quinia; therefore the majority of cases will be found to have commenced in the fall months, and cannot be cured without quinia, if at all. Indeed a large proportion remain uncured under any treatment. Every variety of remedies has been employed, such as Epsom salts with tartar emetic, bismuth in large doses, mercury with chalk and opium, acetate of lead and opium, &c., but none of them have in my hands proved reliable.

The only thing at all deserving to be called a remedy, which I have tried, has been sulphate of copper combined with morphia, quinine, and capsicum. My general formula has been as follows: ℞. Sulphate of copper four grains, sulphate of morphia two grains, sulphate of quinia twelve grains, capsicum four grains. Make twelve pills; take one every four hours. The individual ingredients in this formula may be increased or diminished according to circumstances. For example, should there be a great deal of pain, I increase the morphia. Pain, however, is not always present. Should the discharges obstinately increase in frequency, I increase the quantity of the copper-salt until some degree of nausea is experienced. Wine and other alcoholic stimulants should be used as required, but beer is generally injurious, and even wine will require cautious watching. The diet should be such as is chiefly digested in the stomach, but as nourishing as possible. * * * This plan I adopted at the close of the Mexican war, and have followed ever since, not finding anything better. * * *

Extract from the Report of Surgeon EZRA READ, 21st Indiana Volunteers. *Camp Dix, Baltimore, Maryland, September* 5, 1861.

Diarrhœa has been treated with drachm doses of sulphate of magnesia every three or four hours, for twenty-four or thirty-six hours, followed with quinine until the intestinal tonicity has been restored. This treatment has been in all respects satisfactory to me, and is preferred to the use of astringents and mercurials.

Extract from the Report of Surgeon DE WITT C. VAN SLYCK, 35th New York Volunteers. *Falls Church, Virginia, quarter ending September* 30, 1861.

The 35th New York volunteers was organized June 3, 1861, at Elmira, New York, and remained at that station till July 10th, when they were ordered to Washington. During this period of about five weeks nearly one hundred cases of rubeola occurred among the men, the disease taking on a severe and, in many instances, a malignant form. The sequelæ were more than usually abundant, and laid the foundation of much subsequent disease, which was developed under the influence of exciting causes.

The regiment arrived in Washington July 12th, and was unfortunate in the selection of a camp, much of the ground being inundated by the heavy rains which fell during the latter part of the month. The loss of a portion of the camp equipage by fire and the poor quality of many of the remaining tents made it impossible for the men to keep dry, and the cold drenching rain of the 22d and 23d of July was the exciting cause of more than three hundred cases of diarrhœa and dysentery during the remainder of the month. These cases of diarrhœa were rather severe and obstinate in their character, and usually terminated in dysentery unless promptly checked by remedies; nearly all of them had bilious complications, and were treated accordingly. Blue mass was freely given in the first instance, followed by opiates, capsicum, and stimulants. The value of this treatment may be estimated by the fact that no deaths resulted.

About August 1st the regiment crossed the Potomac and encamped three-quarters of a mile southwest of Arlington house. Here, again, the selection of a locality for the camp was particularly unfortunate. It was a nearly level flat with rising ground on two sides, not susceptible of being thoroughly drained, and covered by a dense growth of wood admitting of neither sun nor air. The ground was covered by a thick layer of decayed vegetable matter. During a rain everything was saturated with moisture, and remained so several days after the weather became clear and pleasant.

At this season of the year the heat was particularly oppressive to men coming from northern New York, and who, though debilitated by previous disease and sudden change of climate, were constantly over-worked in the construction of fortifications, felling timber, and by severe drills. Fever soon made its appearance in the camp, and rapidly increased in frequency and malignity until September 1st, when, at the earnest solicitation of the senior medical officer, the camp was moved to higher ground in the rear of Fort Tillinghast, where it remained till the close of the quarter. During the latter part of August the undergrowth and a portion of the timber was removed, only to admit the sun and increase malarious exhalations. During the months of August and September more than five hundred cases of fever were treated, the duration of which was from four to five days to as many weeks. The first cases were intermittent in type, with a tendency to enteric disease. It soon after took on a remitting form, and finally assumed a low typhoid grade, and in many cases was exceedingly malignant.

The treatment consisted almost entirely of a mild mercurial laxative, generally blue mass, followed by large doses of quinine, and occasionally anodynes and sudorifics. From twenty to sixty grains of the sulphate of quinine per day were administered, and if this did not entirely eradicate the disease within the first week, it modified and reduced its malignancy and duration. No other form of treatment was found efficacious, though other approved remedies were fairly tested. Mixed and complicated cases were of course treated according to indications. During the last stages of the disease stimulants were given with manifest advantage.

In nearly all the malignant cases patches of sudamina and petechiæ covered the abdomen. From the abdominal tenderness and the obstinate diarrhœa which these cases exhibited, it was evident that the intestinal follicles were seriously involved. This condition of the intestines was frequently prolonged, and greatly retarded convalescence. No opportunities were afforded for *post mortem* examinations, and only two cases proved fatal. Convalescence was necessarily slow, and in very many cases relapses followed imprudence in diet and exercise.

After the removal of the camp, febrile diseases were less frequent and milder in character, but although the causes above enumerated were partially removed, yet their effects will doubtless be more or less felt during the autumn and winter.

During the month of September the health of the men gradually improved, and at the close of the quarter fever had sensibly diminished. There were, however, a great number of convalescents who were the victims of various acts of imprudence on their own parts, and of the vicissitudes of the weather and the asperities of the service; diarrhœa, dysentery, and rheumatism were the consequences.

Extract from the Report of Assistant Surgeon Samuel A. Storrow, U. S. A. *Fort Washington, Maryland, for the quarter ending September* 30, 1861.

When first placed as medical officer at this post, I found much tendency to diarrhœa and milder forms of dysentery, produced by the use of the river water, which holds both lime and magnesia in solution. This source of trouble has been remedied for the future by having a well sunk in one of the bastions, which it is believed will afford a sufficient quantity of purer water, though its chemical constituents have not yet been ascertained by analysis.

Extract from the Report of Acting Assistant Surgeon William A. Bradley, jr., U. S. A. *Upton's hill, Virginia, September* 30, 1861.

This command consists of companies A and M, 2d artillery, and company G, 1st artillery, in all three hundred and eighty-six officers and men. The diseases which were most prevalent when I joined the command, August 2, 1861, were cases of acute diarrhœa and a mild form of dysentery, which generally yielded readily to a purge of calomel combined with some cathartic, followed by quinine in small doses. These cases were generally complicated with slight hepatic or splenic congestion. Intermittent fever did not exhibit itself in a decided manner until toward September, when a tolerably large number of cases appeared, mostly among those of our men who had been stationed in Florida or Texas. All the cases have been either of the quotidian or tertian type, and have generally been subdued by moderate doses of quinine.

Extract from the Report of Surgeon Cyrus N. Chamberlain, 10th Massachusetts Volunteers. *Washington, D. C., quarter ending September* 30, 1861.

The 10th Massachusetts regiment was recruited from the hills and valleys of the four western counties of Massachusetts, and is composed of men most of whom had been engaged in agricultural and mechanical pursuits. We were mustered into the service of the United States June 21, 1861, at Springfield, Massachusetts, where we remained in barracks until the 18th of July, when we removed to Medford, Massachusetts, near Boston, preparatory to our departure for the seat of war. We sailed from Boston on the 25th of July, in the steamers S. R. Spaulding and Ben Deford, and arrived in Washington on the 28th, and on the following day moved to Kalorama and encamped on ground just vacated by a New York regiment. We remained at Kalorama about ten days, when, having been attached to General Couch's brigade, we were ordered to march to Brightwood, five miles north of the city of Washington, on the Seventh street road. We again changed our encampment three days later for our present locality, one mile north of our last encampment and six miles from Washington. Our present site is apparently a healthy and salubrious one, on a moderate elevation, exposed on the north and south, and bordered partially on the east and west by groves of trees, through which small rivulets, which supply us with an abundance of tolerable water, find their way.

When I joined the regiment at Springfield I found several cases of measles existing, and although the most diligent efforts were made to prevent the spread of the infectious disease by isolating those already suffering from it, it has continued to follow us until very recently, there having occurred in all more than a hundred cases. I am happy in being able to state that no patient died of this disease, although many of them were very sick, and such had entailed upon them the ordinary sequelæ of rubeola, rendering their convalescence slow and tedious, and making them peculiarly susceptible to disease under the unavoidable exposures of a soldier's life.

The sudden transition of raw recruits in mid-summer from civil to camp life, involving important changes in diet and all the habits of life, together with the exposures incident to such experiences, and the almost irremediable indulgence in the use of green vegetables, which soldiers will obtain, produced their natural effects on the men and gave rise to many cases of diarrhœa, dysentery, &c. The change of location from the cool region of western Massachusetts to the warm latitude of Washington during the most intensely hot days of the season, and the substitution for the pure water of their native hill-sides of the foul, unhealthy water which alone could be obtained during the first fortnight after our arrival, rendered the men specially liable to the above-named affections, cases of which were very numerous, although we were so fortunate as not to lose any men by death.

Our encampment at Kalorama proved to be an unhealthy one. The ground was a hard and sandy soil denuded of grass, thus reflecting the rays of the sun with the utmost intensity, and was bordered wholly on three sides, and partially on the fourth, by dense groves, thus arresting every current of air, and on either side of it ran a small and sluggish stream. The grounds immediately around the encampment had been left in a filthy condition by the previous occupants, and the weather was the most oppressive in point of temperature we had yet experienced, while the regiment had but just arrived from the north. To add to these disease-producing influences, a defect, apparently unavoidable, existed in the commissary department, and the men were compelled to subsist for a period of several days on a diet composed exclusively of salt pork, with a moiety of

salt beef and hard crackers. These combined circumstances served to produce a large number of bowel complaints, and, by debilitating the men, to lay the foundation for fevers during the autumnal months; a result which we then anticipated, and which we have since experienced, though to a less degree than we expected.

Soon after we removed to our present location a season of rainy weather began, which continued from the 13th of August to the 30th of the same month, with very brief intermissions. The temperature was suddenly reduced at the same time, the thermometer marking so low as 56°, which but a few days before stood at 103° in the shade. During this time our men began to perform picket duty, each company remaining out for twenty-four consecutive hours, and returning to sleep on the ground, with no protection but an India-rubber blanket beneath them and a single blanket above them, of course inside their tents. The effect of this exposure was the production of colds, which were soon followed by fevers. The latter were of a bilious remittent type, and some of the cases rapidly assumed a typhoid form. The first cases were of a very severe character, and four of those treated in our regimental hospital have died, and the same number have died at the general hospital. It is proper here to state that most of our sick have been treated in camp. Of those who died here, the first became convalescent and left the hospital for his quarters, but owing to imprudence suffered a relapse, from which he died. The second was violently ill from the first, and was delirious from the earliest stages, his skin literally covered with petechiæ and vibices; he sank after an illness of ten days. The third and fourth had all the phenomena of ordinary typhoid fever, and both died of severe and repeated hæmorrhages from the bowels. As the epidemic progressed the type of the disease became milder, although we still have occasionally cases of a severe character. The treatment which we have employed for the fever has usually been a mild laxative of castor oil and oil of turpentine, often preceded by five grains of blue mass, and full doses of quinine after the operation of the cathartic, with an occasional dose of opium and ipecacuanha.

Extract from the Report of Surgeon Thomas C. Barker, 7th Maine Volunteers. *Baltimore, Maryland, quarter ending September* 30, 1861.

One hundred and thirty cases of acute diarrhœa occurred during the quarter. Most of these cases were attended with little or no pain, and the alvine discharges were generally copious and largely composed of mucus, serum, and water. They are probably to be attributed to change of diet, region, and climate, and especially to the use of fruits, such as melons, peaches, &c., which were eaten with avidity by most of the men.

Extract from the Report of Surgeon David Little, 13th New York Volunteers. *Camp near Fort Corcoran, Virginia, quarter ending June* 30, 1861.

It will be observed that diarrhœa and dysentery have been very prevalent, as well as intermittent fever. Several points might be enumerated in explanation of the origin of the first-named diseases, viz: First, the men are raw troops, unused to the hardships and exposures of camp life, and unlearned in the arts that tend to the health and comfort of the soldier, more especially in that of properly preparing their food; second, change of water. Since their arrival in Virginia they have drunk soft water exclusively, whereas they have lived hitherto in a limestone region and are accustomed to hard water. It may, moreover, be mentioned that while at Camp Lincoln, near the Georgetown ferry and at the foot of the hill from Fort Corcoran, the water used was very foul, with exactly what impurity I was unable to determine. At any rate there is a significant fact in this connection, namely, that these intestinal disorders originated here, and so rapid was their progress that, within a week after their first appearance, sixty-four of the men were ill at one time. Immediately upon our removal to our present encampment, Camp Union, situated about one mile and a half beyond Fort Corcoran on the Fairfax road, diarrhœa began to disappear and has been steadily decreasing, so that now only a few mild cases remain.

Extract from the Report of Surgeon N. F. Marsh, 4th Pennsylvania Cavalry. *Washington, D. C., quarter ending December* 31, 1861.

During the past two months the tendency of every disease has been to assume a typhoid character. A simple attack of diarrhœa would in twenty-four hours render a vigorous man perfectly prostrate, as he would then present all the incipient symptoms of typhoid fever. The number of cases of the latter disease was large, and eight of them have terminated fatally.

Extract from the Report of Surgeon William Frothingham, 44th New York Volunteers. *Hall's hill, Virginia, quarter ending December* 31, 1861.

The 44th New York volunteers was recruited mainly by farmers, mechanics, professional men, and students. Nearly all are from the rural districts. This selection, which was supposed to insure against disease, proved in that respect unfortunate. Unaccustomed to hardships, they have suffered more than many inferior regiments. The first week in camp, measles prostrated over a hundred men. About half of these were quartered in a large house, and although they had no beds other than a single blanket, all recovered. Of those treated in quarters and hospital-tents four died with pleuritis and pneumonia. This remarkable difference was probably due to the humidity of the quarters and tents, while the house-floors, though cold, were perfectly dry. The epidemic has left a large number with a condition of system and lungs threatening phthisis, and some already suffer from that disease.

Malaria exerts a powerful influence in the production of dysentery, as well as tedious remittent and intermittent fevers. The tendency to a typhoid condition is strongly marked in pneumonia and dysentery. Typhoid fever is of the gravest character. It is always accompanied with the peculiar diarrhœa; but the rose-colored eruption has been observed in one case only. No autopsy has yet been obtained.

Extract from the Report of Surgeon JAMES C. STUART, 17th New York Volunteers. *Hall's hill, Virginia, quarter ending December* 31, 1861.

The diseases which have been treated during the quarter have in the majority of cases been attributable to miasmatic influences contracted while in camp at Fort Ellsworth. This has been the predisposing cause, while the exciting causes have been exposure, want of cleanliness and care, and, when opportunity offered, excess in eating and drinking. Most of the fevers have been of a bilious-remittent type, with a tendency to typhoid. Perhaps twelve cases of intermittent fever have occurred. Diarrhœas and dysenteries have been frequent, owing usually to exposures and imprudence in eating. These cases have always been easily managed when the patient would do anything for himself in the way of diet. A few cases have become chronic and are still persisting.

Extract from the Report of Assistant Surgeon JOSIAH F. DAY, jr., 10th Maine Volunteers. *Relay House, Maryland, quarter ending December* 31, 1861.

It will be noticed, in looking over the report, that diarrhœas have been somewhat frequent. They were no doubt owing to a change of climate, water, and food. They all gave way to mild remedies, and some of the cases ceased spontaneously.

Extract from the Report of Surgeon ROGER W. PEASE, 10th New York Cavalry. *Havre de Grace, Maryland, quarter ending March* 31, 1862.

The 10th New York cavalry was mustered into service at Elmira, New York, December 25, 1861, and numbered rank and file seven hundred and forty three men. * * * During the time we were at Elmira rubeola prevailed to a great extent, bequeathing to us the various forms of disease that follow it as sequelæ. The regiment was ordered to Gettysburg, Pennsylvania, the last of December, 1861. The quarters provided for us were insufficient for our accommodation, and their crowded condition added many to our sick list.

In the month of January parotitis became epidemic, continuing through February. Nearly all the cases of orchitis during these months were from metastasis of this disease. These cases required but little treatment. During the month of January pneumonia prevailed quite extensively. It arose from colds contracted on the passage from Elmira to Gettysburg, and from the ill-ventilated and crowded quarters in which the men were placed. The case recorded as pneumonia, that resulted in death, assumed a typhoid character, as did many others in which the termination was more fortunate.

It is pertinent to remark here that company B, which suffered greatly from typhoid-pneumonia, arising out of ill-ventilated quarters, was made the most healthy company in the regiment by introducing into their quarters M'Kinnell's ventilator, which consists of a box within a box, or two hollow shafts, the middle one extending below the outer one in the room, and above the outer one where it pierces the roof. Two of these ventilators were placed in the carriage factory occupied as a barrack by this company, after which sickness rapidly diminished among them, until they scarcely reported a case at sick-call. These ventilators were afterward placed in the barracks erected for the regiment, and this, together with careful policing of the camp, gave us unusual exemption from disease of a serious character.

During the month of February we had thirteen cases of remittent fever and seven cases of pneumonia. These were all mild cases, and required but slight medication.

About the first of March orders were received to remove to Perryville, Maryland, and occupy the quarters of the 14th United States infantry. The 7th of March we entered these quarters, and while we found them commodious and in good condition, we learned that the regiment which had just left had suffered severely from typhoid fever and diseases of like character.

The barracks of the 14th were situated on the eastern shore of Chesapeake Bay, in an elevated and pleasant situation. About four hundred yards from the grounds of the 14th were the quarters of the 11th United States infantry. This regiment, I am informed, notwithstanding their contiguity to the 14th, were almost wholly exempt from disease. Dr. Page, the post-surgeon, states that river water was used by both, the camps were equally well policed, and the general management of each equally good. The only solution he was able to give of the difference in sanitary condition was the fact that the ground of the 14th was difficult to drain; that it had been ploughed more recently than the ground occupied by the 11th, and a good sod had not formed on it. With these facts before me it was my object to render the sewerage as complete as possible, to make the barracks thoroughly clean, and to find a new source from which to obtain our supply of water. The sewers were newly opened, and an excellent spring was found convenient to the quarters and yet exempt from its drainage. The weather soon became settled. and the mud, which had heretofore been very deep, disappeared, and to all appearance everything promised well.

About the 10th instant diarrhœa began to prevail. A few days later symptoms of malarious fevers appeared. On the 26th orders came to move over the bay to Havre de Grace. On the 27th numerous cases of remittent fever were developed, while acute diarrhœa had become epidemic. It is safe to say that during the last twelve days we have had a larger number of sick on our list than for the whole month previous. Two of the fever cases have assumed a typhoid type. The diarrhœal cases obstinately resist the ordinary treatment, quinine being essential to a cure in almost every instance. * * *

Extract from the Report of Assistant Surgeon CURTIS J. BELLOWS, 5th Ohio Volunteers. *Camp near Strasburg, Virginia, quarter ending March* 31, 1862.

During most of the quarter the regiment was posted along the line of the Baltimore and Ohio railroad. It has suffered chiefly from catarrh and diarrhœa, with occasional cases of pneumonia and of intermittent fever. Diarrhœa was the

prevalent disease. In obstinacy and severity it has been unequalled by the autumnal diarrhœa seen north of the Ohio river. The discharges were bilious and mucous in character, often bloody. It was restrained only by large doses of opium and acetate of lead. The occurrence of the disease at this season of the year has variously been attributed to diet, water, &c. My own opinion is that the chief causes of its production have been exposure to sudden changes of temperature and the unusual amount of moisture which has attended this season.

Extract from the Report of Assistant Surgeon HENRY S. SCHELL, U. S. A. *Miner's hill, Virginia, quarter ending June* 30, 1862.

The command consisted of company D, 5th United States artillery, 3d and 5th Massachusetts batteries, and the 4th Rhode Island battery. During the early part of the quarter, while before Yorktown, I found that almost every case of diarrhœa and dysentery resulted immediately from eating hard bread fried in grease, after having been soaked in water, making a very palatable and at the same time indigestible meal. The practice was only ended by making it a punishable offence, and with its cessation there was a sudden and decided diminution in the sick report. A large proportion of the cases which occurred later in the season were accompanied by constant nausea, or some other evidence of irritation of the stomach; these were in most cases quickly cured by the frequent administration of minute doses of calomel and opium, or by the exhibition of the sub-nitrate of bismuth.

Extract from the Report of Assistant Surgeon WILLIAM R. RAMSEY, U. S. A. *Camp near the Chickahominy river, Virginia, quarter ending June* 30, 1862.

With the exception of a slight epidemic of mumps in the early part of April, the diseases of the 11th United States infantry have been during the quarter of miasmatic origin. Cases of remittent and intermittent fevers, and of a diarrhœa which was seemingly produced by the same causes as these fevers, have been numerous. This may be accounted for by the fact that in this notoriously most unhealthy portion of Virginia, the Chickahominy swamps, the men have been much exposed in building bridges over streams and corduroy roads through swamps, after wading all day in water nearly waist deep.

Extract from the Report of Surgeon B. B. LEONARD, 84th Ohio Volunteers. *Cumberland, Maryland, June* 30, 1862.

This regiment was mustered in at Camp Chase, Ohio, and arrived at this place June 14th. The troops are encamped on the first terrace west of the city of Cumberland, on the west bank of Will's creek. The health of the troops has been good, with the exception of diarrhœa, which has been very prevalent. This is probably owing to the soft water, the men having been used to hard limestone water. The change of food has also been a contributing cause of intestinal disease.

Extract from the Report of Surgeon DANIEL O. PERRY, 10th Maine Volunteers. *Camp near Harper's Ferry, Virginia, quarter ending June* 30, 1862.

The water in this region being highly impregnated with lime, caused at first slight diarrhœas, the effect of which was undoubtedly salutary in the end. The cold damp character of the weather during April and the early part of May gave rise to much bronchitis and pneumonia; catarrh was also quite prevalent. It was observable that those who were encamped in tents had much less of these, as well as all other diseases, than those who, while guarding the railroad, were able to use houses as temporary barracks. The month of June found us in the valley of Virginia with marching to do, and many times no covering at night. The weather was warmer than most of the men were used to. On the early appearance of cherries and currants, which were regarded as great luxuries, many of our men indulged extravagantly, and in consequence of this cause and of climatic influences severe diarrhœa and dysentery, as well as typhoid and remittent fevers, prevailed.

Extract from the Report of Assistant Surgeon EDWARD T. WHITTINGHAM, U. S. A. *Camp near Harrison's Landing, Virginia, quarter ending June* 30, 1862.

I found this command, companies G, 2d United States artillery, E, 1st Rhode Island artillery, and B, 1st New Jersey artillery, May 17th, at Cumberland Landing on the Pamunkey river. Since that time we have been constantly exposed to the fatigue of marches, the emanations of the succession of swamps which lay between the above-mentioned place and the point of our extreme advance toward Richmond, and obliged to use water so muddy and impure as to be unfit for drinking. These causes, in combination with the previous exposure of the troops in the marshes about Yorktown, produced a general tendency to malarious fevers and dysenteric affections of the bowels, which are severe in their type and exceedingly unamenable to treatment. Quinia in very large doses, and opium, have been the remedies upon which I have relied. Though the mortality has not been large, the average duration of the cases of sickness has been very long.

Extract from the Report of Surgeon ARTEMUS CHAPEL, U. S. Volunteers, *1st division, 2d corps, army of Virginia, July*, 1862.

An epidemic of diarrhœa broke out in nearly all the regiments during the last ten days of the month, caused principally, I think, by the night exposure to damp cool air and the recent change of tents, commodious and protective ones being replaced by what are miscalled shelter-tents. The disease proved to be mild and easily managed, and it very soon disappeared as an epidemic.

Extract from an Inspection Report of the army of Virginia, by Medical Inspector Edward P. Vollum, U. S. A. *August* 21, 1862.

The troops are sick of the hard bread. They have all been accustomed to soft bread, and they yearn for it cravingly. It could be supplied to them most of the time by having portable ovens in the hands of practical men following close upon the army, and it should be done. Occasionally losses of them would doubtless happen; but this, placed against the satisfaction that would be enjoyed by the men, and the amount of disease that would be prevented by wholesome digestible bread, would not deserve consideration.

Bits of undigested hard bread can be seen in every camp sink, and I have no doubt that its continued use produces some enteric irritation and retards the recovery from diarrhœa and dysentery.

Diarrhœa maintains its place as a prominent camp disease in this army, and furnishes more cases than any other complaint. Quinine, fresh vegetables, and fruits have relieved many cases, and seem to point to a constitutional condition on which the disease may be based. The frying-pan causes the disease frequently, and many cases are attributable to green fruits and imperfectly masticated hard bread. The treatment of diarrhœa varies according to the proclivities of the medical officers; but the plan which receives most favor, and which seems to be most successful, is the administration of medium doses of sulphate of magnesia or Rochelle salt, with a little laudanum or extract of ginger. In many cases of diarrhœa there is a sluggish condition of the liver and an obstruction of the portal circulation; as a consequence the mucous membrane of the intestines is congested, which is relieved by the exosmotic action of the salt.

Extract from the Report of Surgeon Benjamin Lee, 22d New York State Militia. *Harper's Ferry, Virginia, quarter ending August* 31, 1862.*

This regiment having been called out for but three months, the following report covers the whole period of its organization. Three weeks of this time were passed at Camp Monroe, Patterson Park, Baltimore, and the remainder of the time at Harper's Ferry, Virginia.

At Baltimore some difficulty was experienced in procuring the necessary tools for police purposes, while the nature of the soil was such as to make it impossible to construct dry sinks. The sanitary condition of the camp was, therefore, scarcely so satisfactory as could have been desired. A poudrette factory in our immediate neighborhood was occasionally very offensive, but I could not discover that either it or the unfortunate condition of the sinks, which were located at an unusually great distance from the camp, exerted any injurious influence on the health of the men. In fact we could scarcely be said to have a sick list beyond a few cases caused by indiscretion in diet and exposure to the unusually inclement weather. In view of the latter, I took the precaution to have as many fires as possible around the camp at night, especially during cold storms, of which we had many.

Our first encampment at Harper's Ferry was in a comparatively healthy situation, and the sick continued to be few. In a short time, however, the departure of Colonel Mulligan's brigade left the intrenchments without protection, and we were obliged to fall back to take charge of them. Our new ground had been camped on over and over again, and had last been used as a cavalry stable. The Government houses behind the intrenchments, as well as almost all the houses in the villages of Harper's Ferry and Bolivar, were filthy beyond expression, having been occupied as quarters by the troops of both armies for more than a year previous. A vigorous system of police was at once initiated, but we were greatly embarrassed by the difficulty of obtaining wagons. Lime was also scarce and of inferior quality, the inhabitants of the region having entirely suspended their lime-burning operations. I solicited the co-operation of the medical officers of the general hospital in policing the entire town, the civil municipal authorities having ceased to be, and the usual sanitary precautions having therefore been entirely neglected. The altered sanitary condition of our camp soon began to tell, notwithstanding our best efforts. Diarrhœa, assuming in many cases a dysenteric type, although not generally of severe grade, attacked the men by dozens, so that in the course of three weeks, or by the fifteenth of July, more than one-tenth of the regiment were on their backs. The remedy which I found by far the most satisfactory in the treatment of this class of cases, quite at variance with my preconceived opinions, was sulphate of magnesia, followed up by some form of opium, although later in the season I was obliged to prescribe the latter drug with extreme caution in consequence of its torpifying action on the liver. The treatment indicated appeared to exercise a most happy soothing effect on the irritable and inflamed mucous membrane, relieving the tormina and exhausting tenesmus almost immediately on the first evacuation. Castor oil I found acted much less kindly than sulphate of magnesia.

As the intense heat of the latter part of July and August began to make itself felt, deficient action of the liver became common, as attested by the clay-colored deposits which so largely composed the contents of the sinks; by persistent diarrhœas or equally persistent constipation, and in many cases by a remarkable depression of the vital forces, without febrile action, which resisted the combined powers of quinine and stimulants. Nothing but a prompt removal to a northern climate appeared to suffice in such instances to bring up the tone of the system to anything like a working standard. Mercury with chalk I found to be the most efficient agent in stimulating the hepatic secretion and checking the accompanying diarrhœa. Still later, passive congestion of the mucous membrane of the bronchial tubes developed itself, as a consequence of this continued interference with the portal circulation, and the extra amount of labor thrown upon the lungs by the failure of the liver to do its part in decarbonizing the blood, and we had the somewhat singular phenomenon of an epidemic of bronchitis during a period of intense heat, and while the nights were as hot and dry as the days.

As might have been supposed, the best remedy for this condition was to be found not in the use of expectorants, but of the mercurials. Taken in its incipiency, a single dose of blue mass rarely failed to relieve the attack; but if neglected, it became, in some instances, very obstinate. These cases are entered on the report under the head of bronchitis, although the inflammatory element seemed to be almost entirely wanting.

The final manifestation of the hepatic disturbance was jaundice following intense cephalalgia and enteralgia, the latter of such severity as closely to simulate enteritis or even peritonitis.

* This report is published in full, with some additions, in the American Medical Monthly, October, 1862, p. 241.

The natural advantages of our situation were great. The camp was pitched upon a steep hill-side, some two or three hundred feet above the rocky bed of the Shenandoah. The soil was hard and slaty, affording a perfect surface drainage. The company streets were kept scrupulously clean, and when at length we obtained wagons for our own use, the outer limits of the camp were also in good condition. Up to that time it was a very difficult matter to police them thoroughly. The exposure was southwesterly, looking directly up the valley of the Shenandoah.

Until the middle of August the nights were hot and there was little dew. After that time they became very cold and damp, the change being extremely abrupt, and the malaria which prevails in all this valley began to make itself felt, notwithstanding the apparently favorable conditions of our location. This was manifested not by regular attacks of chills and fever, but rather under the masked form of the disease, perhaps owing to the fact that most of the men had used quinine more or less freely as a prophylactic, an unaccountable lassitude and malaise, a feeling of dulness about the head, and vertigo, persistent headache, rarely rigors, not unfrequently fever without the chill, and in two singular cases a well-marked intermittent torticollis.

One single case of typhoid fever occurred, which terminated favorably.

The use of an unaccustomed water containing a small amount of lime undoubtedly aggravated the intestinal fluxes as well as gave rise to a great deal of colic. Nothing appeared to act so well in these latter annoying cases as capsicum combined with camphor, opium being in great measure contra-indicated by the tendency to hepatic congestion.

The remittent fever, which prevailed to a slight extent, was of a mild form, rarely lasting more than a week, but sometimes leaving the patient's strength prostrated for a much greater length of time.

The 12th regiment New York State militia was encamped within a quarter of a mile of our own ground. Its members were subjected to precisely the same characteristic influences; yet its sick list, while it presented precisely the same variations as our own, was never as large by one-fourth. The two regiments were about equal in numbers. I attribute this difference to four causes: First, to the classes of men composing the two regiments, the twelfth being made up of the ordinary material of volunteer regiments, while our own was composed of merchants, professional men, and clerks, a class wholly unused to the labor, privations, and exposure to which they were necessarily subjected. Second, to the fact that the twelfth occupied Sibley tents, while the twenty-second was almost entirely supplied with the wedge-tent. The former could easily be furled daily, and thus the most perfect ventilation of the ground secured, while the latter must be entirely struck in order to effect the same result, which could never be accomplished oftener than twice a week, rarely so often. Third, to the saturation of the soil on which we were encamped with the emanations, excretions, and offal of regiments which had preceded us for many months previously. Fourth, to our more immediate proximity to the foul houses of the village.

I have but one death to report, that of our Colonel, James Monroe, formerly of the 6th United States infantry, a man who possessed in an eminent degree the affection and confidence of his command. [Case 95*.] While the regiment was in Baltimore Colonel Monroe was seized with a congestive chill, which left him greatly prostrated. Fearful of a recurrence, which physicians in Baltimore thought might prove fatal, he remained in that city for a period of fifteen days after the departure of the regiment for Harper's Ferry. Anxiety for the safety and welfare of his command led him to follow us while still much debilitated. During the first fortnight he did not seem to lose strength, but his nervous system was in a most unsatisfactory and excitable condition. At the end of this time he was attacked with mild febrile symptoms, which gradually abated, but which determined me to send him north as soon as he should sufficiently recover to make the journey. On the afternoon of July 29th, however, after a natural though somewhat profuse evacuation from the bowels, he was seized with excruciating pain in the abdomen and in the region of the anus, so severe as to cause syncope. I immediately administered opium in full doses, both by the mouth and rectum, with the effect of moderating the pain, but not of reducing the frequency of the pulse, which was weak and about 150. During the next day his condition was not materially altered. I administered in the morning ten grains of calomel, followed later in the day by sulphate of magnesia with capsicum, but did not succeed in procuring an evacuation. The pains became again very violent, not yielding to anodynes, and so continued until toward midnight of the 30th, when they ceased entirely, and vomiting of bilious matter supervened, with hiccough and eructation. The pulse rose in frequency and lost in force, the skin became cold and covered with a profuse perspiration. Carbonate of ammonia and whiskey, administered in very large doses, both by the mouth and by enema, artificial heat and stimulating frictions, failed to induce the slightest reaction. The nervous jactitation became more and more distressing, and he finally succumbed at 6 p. m., July 31st, shortly after rising to have a liquid stool.

The short duration of the attack, the sudden onset of the pain and its agonizing character, the great prostration and nervous anxiety, and the fatal result in thirty-six hours after the invasion, appeared to me to point to peritonitis, probably the result of a perforation of the intestine; but as I was unable to obtain an autopsy the diagnosis must remain conjectural.

Extract from the Report of Surgeon John W. Foye, 11th Massachusetts Volunteers. *Army of the Potomac, quarter ending September* 30, 1862.

This regiment reached Harrison's Landing on the 2d of July, 1862, and on the 5th went into camp about five miles from the landing. The prevalent disease was diarrhœa of a peculiar and exhaustive character, marked by such a uniformity of symptoms that a single case will be a sufficient example of the general character of the disease. The patient presents himself at sick-call complaining of a general feeling of malaise. An examination of the tongue exhibits a yellow coating more or less thick, according to the length of time since he was first attacked. There is a slight headache, more or less pain in the back, and in most cases nausea; the latter symptom occurring when the desire to stool is urgent, and at once relieved by a discharge from the bowels. The discharges are profuse, of a thin watery character, unattended with pain, and often as many as fifteen a day. In those cases in which the disease has existed four or five days or upwards there is great emaciation. The yellowness of the

* This case belongs to the chapter on fevers, but is given here so as not to separate it from the rest of Surgeon Lee's report.

skin which generally characterized this disease rendered the inference irresistible that it was of miasmatic origin, and it was probably contracted during our stay in the swamps of the Chickahominy. Various forms of treatment were instituted, but that found most efficacious was the exhibition of a mercurial at night, usually a blue pill, followed by full doses of quinine through the day, the patient being restricted during treatment to a strictly farinaceous diet.

Extract from the Report of Surgeon STEPHEN ROGERS, 7th New York State Militia. *Baltimore, Maryland, quarter ending September* 30, 1862.

A fruitful cause of the bowel diseases which continued till nearly the end of August was the inadequate provision of privies, forcing the members of the command to wait their turn at the sinks for, in many cases, an hour or two. This continually resulted in failing to secure the daily and regular alvine evacuation, and was thus the cause of torpidity, constipation, and diarrhœa.

Extract from the Report of Surgeon GEORGE W. MARTIN, 4th Maine Volunteers. *Camp near White's Ford, Maryland, quarter ending September* 30, 1862.

When I joined the 4th Maine at Harrison's Landing I found a large number on the sick report suffering from diarrhœa, which had a strong tendency in many cases to assume a typhoid form. The causes of this appeared to be the fatiguing marches on the Peninsula, the severe labor and exposure in the Chickahominy swamps, the rations deficient in vegetables, and improperly cooked, the water, which was often obtained from stagnant pools abounding in decayed vegetable matters, and the debilitating effects of a southern climate. The treatment found most beneficial in a majority of cases consisted in the use of tonics (iron and quinine) and stimulants, preceded by a mercurial cathartic. At present the principal cause of diarrhœa in camp is the irregular manner in which the soldiers cook and eat their food. Some of them eat five or six fried dishes, or more properly messes, during the day. There is always an increased amount of diarrhœa after beans are issued to the men, especially in hot weather. I have noticed that cases of diarrhœa of several days' standing have been entirely cured on a march, and without medicine, when the soldier could get only hard bread and raw pork, with scanty time for three meals a day.

Extract from the Report of Surgeon J. THEODORE CALHOUN, 74th New York Volunteers. *Camp near Alexandria, Virginia, September* 30, 1862.

The 74th New York was sent to Washington, D. C., in the latter part of July, 1861, and went into camp near Good Hope, on the Maryland side of the Eastern Branch. October 15th, the organization was mustered into the service of the United States, and shortly after moved to a camp in southern Maryland, near Port Tobacco. While here a large proportion of the men were sick, intermittent and remittent fevers being common, and typhoid fever not unfrequent. In December the regiment moved to Liverpool Point, on the Potomac river, where they remained till spring. They occupied tents until some time in February, when they moved into rude log barracks which they had built. The sick list was large. We had an epidemic of measles, and a number of cases of typhoid fever, three of whom died. Coughs, colds, and rheumatism were unusually prevalent; there was also a good deal of diarrhœa, which at times appeared to be due to the use of the water of the Potomac river for drinking purposes.

During the first week of April, 1862, the regiment embarked for the Peninsula, landed at Ship Point, and took part in the operations before Yorktown. May 5th, we were engaged in the battle of Williamsburg, and had thirty-nine killed and one hundred and ten wounded out of a force of five hundred men. We were also engaged at Fair Oaks, June 1st. Shortly after this a peculiar form of fever presented itself, characterized by an extremely weak pulse, great prostration, suffused eyes, vertigo, and anorexia. Its duration was generally from four to five days. The treatment employed was usually a mercurial cathartic, followed by ten grains of quinine three times a day. On the 25th of June the regiment participated in the battle of Old Tavern, losing two killed and about thirty-five wounded. Subsequently we took part in the battles of Peach Orchard, Savage Station, and Malvern Hill, losing about twenty in killed and wounded. During all this time diarrhœa and dysentery have been the most common complaints, and it may not be improper to observe that they always increased in proportion as the men were crowded together, while fresh provisions invariably cut down the sick list.

After the regiment went into camp near Harrison's Landing, the men being in Sibley tents, we had a model camp in every respect. Every attention was paid to the observance of proper hygienic rules, yet, despite of all, we continued to have an unusual amount of sickness, especially diarrhœa and dysentery. The bowel affections yielded readily to treatment, yet they were continually recurring. Two deaths occurred: one from sunstroke, the other from an attack of cholera morbus (produced by eating canned lobster) supervening on dysentery. These were the only deaths from disease while on the Peninsula.

Leaving Harrison's Landing about the middle of August, the regiment marched to Yorktown. No sooner had the men reached the corn-fields than they fed greedily upon the green corn, eating immoderately of it; yet diarrhœa ceased as if by magic. Before leaving camp every one was more or less troubled with it. One day out of camp, living on green corn and unripe apples, and bowel affections disappeared. I witnessed this effect in my own person. The change from a crowded camp ground to the fresh country air probably was not without its influence.

Extract from a Report by the same, to Medical Inspector EDWARD P. VOLLUM, U. S. A. *Army of the Potomac, October* 10, 1862.

The 74th New York spent the winter of 1861-'62 in camp and on picket duty along the Maryland shore of the Potomac, and during the following spring and summer took part in the operations of the army of the Potomac on the Peninsula and in Virginia and Maryland. Perhaps the disease which was most frequent during all this time was camp diarrhœa or dysentery.

The causes of it are very varied. That which must rank first is crowding men together. Whenever we have been camped by ourselves, camp diarrhœa has been almost absent; crowd regiments all around us, and our sick list is full. At Yorktown and Harrison's Landing, where the army was camped together, camp diarrhœa was unusually prevalent. Bad or poor diet, salt meat in excess, with a want of fresh provisions in sufficient quantity, have also acted as causes. At Harrison's Landing camp diarrhœa affected nearly every one. On our retreat from there to Yorktown the men subsisted almost entirely upon green corn, of which they ate immoderately, and fruits, many of them unripe, yet diarrhœa ceased as if by magic, and did not recommence until we came back to the salt meat diet. The food is too frequently improperly cooked. Badly kept sinks also produce diarrhœa. A well man will, I believe, sometimes get diarrhœa by sitting upon sinks used by patients affected with that disease. Disinfectants, the best of which I think is Cormes's coal-tar and gypsum, (carbolic acid,) are useful where they can be obtained. Impure water loaded with organic matter, changes of temperature, malaria, and the impure gases generated on battle fields, also act as causes.

Extract from the Report of Assistant Surgeon W. F. Tibbals, 5th Ohio Volunteers. *Harper's Ferry, Virginia, quarter ending September* 30, 1862.

During the month of July the 5th Ohio was stationed at Alexandria, Virginia, for the purpose of recruiting. The camp was situated upon the first heights from the Potomac. Police regulations were strictly enforced, and the diet was much better than we ordinarily received. The water was from springs, and we suffered only from diarrhœa, constipation, and catarrh. About the first of August we took the field under General Pope. Our campaign upon the Rappahannock lasted during the month of August, and was one of continual exposure. A number of the men had neither shelter-tents nor blankets. The diet was principally hard bread and coffee; beans and rice were never issued, meat not over four days in the week. Diarrhœa raged to an alarming extent, and was almost universally of a bilious character. I attribute it entirely to the diet. The next most frequent disease was rheumatism, incident to the exposure. During our campaign in Maryland the number of cases of diarrhœa increased, and ordinary prescriptions had no effect whatever. Since our arrival in this camp we have secured a more nutritious diet, and the number of patients with diarrhœa has decreased.

Extract from the Report of Surgeon Samuel F. Forbes, 67th Ohio Volunteers. *Camp near Suffolk, Virginia, quarter ending September* 30, 1862.

One fact in respect to the diarrhœas deserves to be mentioned, namely, that when the 67th Ohio advanced toward Malvern Hill and the men got green corn, new potatoes, and other vegetables, and consumed large quantities of them, their diarrhœas were either entirely cured or greatly benefited. This fact, of which there need be no doubt, for my opportunities of judging were both numerous and excellent, corresponds with the views I have always held since I entered the service, that more vegetable food should be supplied to the troops.

Extract from the Report of Assistant Surgeon Charles S. Wood, 66th New York Volunteers. *Bolivar Heights, Virginia, quarter ending September* 30, 1862.

I joined the 66th New York at Warrenton Junction in March last. There the prevailing diseases were severe colds, diarrhœa, and rheumatism. After we reached Ship Point, on the Peninsula, the same diseases prevailed in an increased degree. At Cheeseman's Landing many cases of bilious remittent fever occurred, and diarrhœa, which became still more common, often passed into dysentery. About April 15th we arrived before Yorktown. Here diarrhœa continued to be the principal complaint, and it was noticed that an increased number of cases always reported the day after beans were served. Moreover, evidences of malarial influence were observed in nearly all the cases, and a combination of quinine and rhubarb was found to be the most efficient mode of treating the disease. We had also many cases of intermittent and of typhoid fever. The latter disease was of shorter duration than ordinary enteric fever, and the rose-colored spots were seldom observed. Quinine was found essential in the treatment. Most of the cases recovered in from ten days to two weeks, but some persisted and were sent to northern hospitals, where many of them remained three or four months before they fully recovered. At Cold Harbor this form of fever became more frequent as well as more severe, and nearly all the men had more or less diarrhœa. The fever cases often began suddenly with a raging delirium, which lasted from five to twelve days and then generally subsided. In other instances delirium did not set in until the fever had lasted some days, and these were the most troublesome cases. The treatment found most efficient was quinine, given in five-grain doses every four hours. Many of these cases had recovered before we reached Fair Oaks, others were sent to the rear, and several died.

At Fair Oaks the disease became still more virulent. Delirium was usually the first symptom, followed immediately by hot, dry skin, tongue red at the edges, creamy on the surface, pulse 100 to 120. Cramps in the extremities were common, and diarrhœa became troublesome and was accompanied by tympanites. Brandy and quinine, the latter in ten-grain doses every four hours, were found to be the most reliable agents in the treatment. Most of the cases were convalescent by the twelfth day, and returned to duty by the end of the third week. About this time also scurvy manifested itself in an unmistakable manner, and during the month of June nearly half our men showed symptoms of it. Fresh vegetables were asked for, but owing to the difficulty of transporting them the quantity obtained was too small to prove efficient. A reasonable supply of lemons was obtained, however, and soon effected the desired result. About the same time an infusion of white-oak bark (*quercus alba*) was prescribed to our diarrhœa cases with excellent results. Both fevers and diarrhœas began to subside when we reached Harrison's Landing, and showed a wonderful improvement after we reached Alexandria in the latter part of August.

Extract from the Report of Surgeon De Witt C. Hough, 7th New Jersey Volunteers. *Alexandria, Virginia, October* 1, 1862.

The 7th New Jersey reached Harrison's Landing July 2, 1862, and encamped on elevated ground, in a dense wood with a thick growth of underbrush, requiring much labor to make the ground habitable, after which it was tolerably healthy, though the want of a sufficiency of good water was severely felt. The men on arrival were much worn out by their previous labors and privations. The prevailing complaints were those arising from exhaustion, especially diarrhœa, and some intermittent fever. While here we obtained a hospital tent, abundant supplies of medicines, sanitary articles, ice, lemons, &c.

In diarrhœa I found much benefit from acetate of lead and opium in divided doses, also from decoctions of the *liquidambar styraciflua* and of the root of *rubus villosus*, which were used with much advantage in the more recent cases. Farinaceous diet and perfect rest were essential to recovery.

Extract from the Report of Surgeon Alexander J. McKelway, 8th New Jersey Volunteers. *Camp near Alexandria, Virginia, October* 15, 1862.

The 8th regiment of New Jersey volunteers was mustered into the service of the United States at Trenton, New Jersey, August 29, 1861. It remained in that vicinity until October 1st, receiving recruits until it numbered about nine hundred men. We arrived at Washington, D. C., October 2d, and encamped on the evening of the same day on Meridian Hill, where we remained until December 1st. The camp-site was all that could be desired for elevation, purity of air, and facility for drainage, and yet, from changes in their habits of life and difference of water and climate, the men suffered severely from diarrhœa. Several cases of dysentery of grave character occurred, also typhoid fever to some extent, together with three cases of variola.

It seems worthy of note that quinine, combined with the astringents and mercurials, given in diarrhœa or dysentery, was thought to be beneficial in some cases of an obstinate character. In this connection, it may be remarked that during the month of October the weather was unusually warm, and to those who, in a more northern latitude, had never at that season of the year been subjected to such a degree of heat, very oppressive; also that malaria had much to do in producing the obstinacy of those cases of disease which have been referred to.

November 30, 1861, we moved to Budd's Ferry, Maryland, landing at the mouth of Mattawoman creek, and on the third day after encamped in a pine forest, which was our resting-place for the winter. The soil of the camp was a sandy loam, with tough clay subsoil, retaining water in large quantities, while between the encampment and the Potomac river a large marsh intervened. During the month of December acute and chronic rheumatism and diarrhœa were the prevalent diseases, induced by exposure on picket duty, which had to be continued during the entire winter.

During the latter part of the month of February and through the month of March rubeola prevailed in the regiment to the extent of about thirty cases. Although the disease was of a severe type, yet none of the cases died, but some of them were followed by tuberculosis and bronchitis, which caused the discharge of several men. During these months typhoid fever and typhoid-pneumonia prevailed to a considerable extent, and were of a grave and severe type. Four deaths occurred from these last-mentioned forms of disease.

As the weather became warmer the effect of malaria became visible in the prevalence of intermittent and remittent fevers, which, however, yielded readily to treatment. On April 5th we embarked for the Peninsula, leaving thirty-five men in the hospital of Hooker's division at Budd's Ferry. To this hospital there were sent from this regiment, as well as from the whole division, many debilitated from the effects of rubeola and typhoid disease, many afflicted with intermittent, remittent, and typhoid fevers, the victims of chronic rheumatism, and those who were broken down and infirm, numbering in all five hundred and twenty men from a division of fourteen thousand. The passage occupied seven days. The men, crowded on transports, suffered much from the inclemency of the weather and from the bad quality of the water furnished them. Diarrhœa made its appearance in a large number of cases previous to landing on the 12th of April at Ship Point, Virginia, from whence the regiment next day marched to Yorktown. Here the encampment was crowded in consequence of the large number of troops occupying the ground. Water was procured with difficulty, owing to its great depth from the surface; constant exposure on duty taxing the energies of the men to the utmost, digging trenches amid rain and storm, and the performance of picket duty, told with fearful effect upon their health. Men never worked harder than they did from the time of their landing until May 4th. Diarrhœa, camp dysentery, remittent and intermittent fevers, as well as typhoid fever of grave type, made their appearance. The sick list averaged from one hundred to one hundred and twenty daily. There were two deaths from dysentery and one from typhoid fever. More than sixty men were sent to general hospital. On landing at Yorktown the command had numbered eight hundred and forty-five men.

May 4th, the regiment took up its line of march for Williamsburg. The roads were horrible, the mud being knee deep, and the march, which was continued until 12 o'clock p. m., was resumed at 4 o'clock on the morning of the 5th. This was severely felt by men who had eaten nothing since the previous day, and who had lain in the mud during the four hours allowed them for rest. Without breakfast they were brought into action, and did their part faithfully during seven hours.

The mean strength of the regiment in this action was six hundred all told, and its loss was one commissioned officer killed, eleven wounded; enlisted men, thirty-four killed, one hundred and fifty-eight wounded—total, two hundred and seven. As soon as the wounded were attended to (no amputations being necessary) they were shipped to various hospitals from Briar Creek Landing.

The regiment encamped near the battle-field until May 11th. The long-continued rains had rendered the site of the camp almost a marsh, and the diseases which had prevailed at Yorktown were aggravated in frequency and intensity. On the 11th the march was resumed. The regiment remained for three days at Burnsville, and then advanced, passing by Slatersville, New Kent Court-House, Cumberland, and Baltimore Cross Roads, to Bottom's Bridge. This march to Fair Oaks, which was reached on May 25th, was performed amid a constant rain-storm and over roads rendered almost impassable by mud.

Dysentery, diarrhœa, intermittent and remittent fevers were the attendants of the regiment, and many cases of these diseases were sent to the transports at West Point. On the 31st this regiment, together with the 7th New Jersey, was detailed to guard the railroad bridge, rifle-pits, &c., near Bottom's Bridge, the remainder of the brigade being engaged in the battle of Fair Oaks. The aggregate strength of the regiment here was about four hundred men. In a few days the regiment rejoined the division at Fair Oaks and did duty in the advance. The duty was harassing and exhausting: on picket one day, and at work on fortifications and in trenches knee-deep in water the next. The enemy was close in front and the firing between the pickets constant, preventing the men from securing necessary repose. The encampment was a perfect graveyard. Within the lines the dead were unburied, lying on the surface of the ground with but a sprinkling of earth thrown on them, while immediately without the dead bodies of men and horses were quite exposed or but slightly covered with brush. Just outside of the camp the bodies of thirty dead rebels were one day counted by an officer of this regiment, whose attention was directed to their place of sepulchre by their feet projecting from beneath the brush thrown over them. Here the suffering of the men from the want of water suitable for drinking was terrible. Efforts to dig wells (one forty-five feet deep was dug) only resulted in procuring water still more unfit for use than that nearer the surface. The air was filled with a most horrible stench, arising from the putrefaction of dead bodies on every side. As might be expected from such a combination of evils, the health of the men rapidly deteriorated. Fevers of the types before prevalent increased in intensity and numbers; diarrhœa and dysentery became more rife; and several cases of *coup de soleil* occurred, occasioned by exposure to the sun's rays during the intense heat of that period.

The regiment remained at Fair Oaks four weeks, during which time from seventy-five to one hundred men were lost to it by sickness and death. One commissioned officer and two privates were killed on picket duty, and ten privates wounded. Every few days a number of broken-down and diseased men were sent to general hospital at White House, where six of them died. The health among the survivors of those sent to hospital was, in a large number of instances, so seriously impaired as to render them totally unfit for duty, while the seeds of disease planted in the swamps of the Chickahominy developed themselves among those remaining with the regiment for weeks afterward.

On Saturday, June 28th, the order was given for the army to retreat. On that day this regiment was on picket duty, and remained where it was till noon of the 29th, when it commenced gradually retiring in order along the Charles City road until it reached the cross roads of the same name, some fifteen or eighteen miles from Fair Oaks, the rear guard constantly skirmishing with the enemy. During the seven days' fight, while the army continued its retreat, this regiment, though equally exposed with the rest, sustained no casualties. Some thirty-five men belonging to it, who were left in the hospitals at Savage Station, Bottom's Bridge, and White House, were taken prisoners by the enemy. July 3d, the army reached Harrison's Landing.

Extract from a Report by the same, to Medical Inspector Edward P. Vollum, U. S. A. *Army of the Potomac, October* 20, 1862.

* * * By the time the 8th New Jersey reached Harrison's Landing, it was reduced to less than three hundred men. Scurvy had made its appearance, and manifested itself with more or less intensity in almost every man. Many of the cases of diarrhœa and dysentery had now become chronic. Every form of mercurial and astringent was used, with but little effect. The disease might appear checked, but the improvement of to-day was lost on the morrow, and it was only when large and frequent doses of quinine were given that any control was exercised over an evil which seemed at one time to be beyond remedy. The effect of this remedy indicates the influence of miasma in the production of the disease. The symptoms appeared to be aggravated by the use of hard bread, fragments of which were passed undigested by the sick.

Extract from the Report of Surgeon William R. Blakeslee, 115th Pennsylvania Volunteers. *Camp near Alexandria, Virginia, October* 20, 1862.

June 26, 1862, the 115th Pennsylvania left Camp Curtin, Pennsylvania, for Fortress Monroe, Virginia, arriving there June 28th. July 6th, we took passage by steamboat for Harrison's Landing, where we encamped July 9th, and remained till the middle of August.

The prevailing disease while on the Peninsula was acute diarrhœa. There were also some three or four cases of typhoid fever, six of common continued fever, six of rheumatism, five of colic, and some other cases of disease which I cannot specify on account of the loss of our records. The cases of diarrhœa numbered about two hundred.

This disease in many instances yielded readily to the following prescription, which seems to be especially applicable to the diarrhœa of irritation. ℞. Dilute sulphuric acid two fluid drachms, compound tincture of cardamom three fluid drachms, white sugar half an ounce, mint-water six fluid ounces. Take two tablespoonsful every hour or two. In the cases attended with much pain the mixture was preceded by a grain of opium. When the compound tincture of cardamom was not accessible, I substituted the compound spirits of lavender with good effect, the cardamom tincture, however, being preferable.

Creasote is another remedy for diarrhœa from which I have found much benefit, and particularly in cases attended with offensive discharges, and combined with chalk mixture, which forms an excellent adjunct in cases attended with acidity. ℞. Chalk mixture four fluid ounces, creasote eight drops, laudanum two fluid drachms. Take a tablespoonful every hour or two. When the stools are alarmingly copious, the addition of ten grains of tannic acid will mitigate and often completely subdue the malady. Whiskey and quinine were administered as a prophylactic with apparent benefit.

Extract from the Report of Surgeon Harvey E. Brown, 70th New York Volunteers, *to* Medical Inspector Edward P. Vollum, U. S. A. *Army of the Potomac, October* 20, 1862.

In April, 1862, the 70th New York was moved on transports to Ship Point, Virginia, and from that point marched to take its part in the siege of Yorktown. Here the health of the regiment continued good in the main, although a number of cases of

subacute rheumatism appeared, the result evidently of exposure to the weather in the trenches. The usual amount of camp diarrhœa and dysentery also prevailed, due I think, both here and previously while we were in southern Maryland, to over indulgence in the pies, cakes, &c., obtained at the sutler's. Those who did not trade with the sutler were not thus attacked. * * June 27th, we encamped on the battle-field of the Seven Pines, surrounded by the graves of those who fell in that action; living in an atmosphere impregnated with the most horrible effluvia; drinking water dug from but three or four feet below the surface; with extremely insufficient supplies; obliged to do twenty-four hours' picket duty out of every seventy-two, and on the intervening days to work in the trenches. Under these circumstances it is not to be wondered that the men got sick. More than half the regiment was constantly on the sick report, chiefly with subacute rheumatism and camp dysentery. This latter disease I found much more difficult to manage than hitherto. The ordinary remedies utterly failed to produce any good effect, and the only satisfactory result was obtained from the use of mercury with chalk, quinine, and Dover's powder, as in the following formula: ℞. Mercury with chalk five grains, quinine three grains, Dover's powder seven grains. Take at intervals of from two to four hours. This treatment, with rest and light diet, generally relieved the disease, if taken in the beginning, in a few days.

Extract from the Report of Assistant Surgeon WALTER B. MORRISON, 3d Michigan Volunteers, *to* Medical Inspector EDWARD P. VOLLUM, U. S. A. *Army of the Potomac, October* 25, 1862.

The 3d Michigan was mustered in June 10, 1861, at Grand Rapids, Michigan; took part in the first movement to Bull Run, and has since accompanied the army of the Potomac. We suffered from an epidemic of measles while at Grand Rapids, and since we joined the army of the Potomac the prevailing diseases have been malarial fevers, diarrhœa, and dysentery. The last two affections were attributed, during the early part of our service, to change of climate, habits, mode of life, &c. At a later period, while on the Peninsula between the York and James rivers, Virginia, the diarrhœas were generally of a scorbutic character, as was proved to be the case by the prompt relief afforded by extra issues of vegetables and vegetable acids.

Extract from the Report of Assistant Surgeon CHARLES E. CADY, 138th Pennsylvania Volunteers. *Relay House, Maryland, October* 31, 1862.

It will be observed, in the accompanying report of the 138th regiment of Pennsylvania volunteers for the month of October, 1862, that diarrhœa and typhoid fever have been the prevailing diseases. In their general characters the diarrhœas were such as are usually met with among those who have experienced changes in air, diet, and mode of life. Copious watery stools, slight fever, nausea, loss of appetite, red scanty urine, vertigo, slight abdominal pain, indigestion, flatulence, &c., were the prominent symptoms. The general plan of treatment adopted consisted in the use of free doses of opium combined with calomel or acetate of lead; but quinine and brandy often succeeded when other modes of treatment failed.

In regard to typhoid fever, many of our cases were of the most aggravated character. The invasion of the disease was often most rapid and prostrating. In several of the cases the men performed duty the day before reporting themselves ill, and upon the third or fourth day after, all the peculiar symptoms of the disease would be well-marked.

Our mortality has been low, considering the number of cases treated: as low, indeed, as is usual in private practice. The treatment adopted was that most in vogue in the Pennsylvania hospital, Philadelphia, viz: treatment of symptoms as they arise. Good, full, and easily digested diet, milk and brandy in punch, eggs, Dover's powder, castor oil, sinapisms, neutral mixture, &c. The camp has been rigidly policed daily; the sinks deep and well hidden; cooking utensils well cleaned after use; food well cooked. The water used is of most excellent quality, slightly impregnated with iron. The general temperature of the air during the month has been high, and the weather dry, with westerly winds. The camp is located on a high ridge of land on the north bank of the Patapsco, ground dry and hard, no shade. The food used by the men has been of a good quality. I have been inclined to attribute many of the cases of diarrhœa to the use of pastry of various kinds sold by the sutler, although frequent cases occurred in those who used nothing of the kind. The cases of respiratory disease were of a mild although well-marked character, yielding in a few days to rest and ordinary antiphlogistic treatment.

Extract from the Report of Surgeon WILLIAM H. WHITE, U. S. Volunteers, on duty with the 4th Pennsylvania Cavalry. *Potomac Creek Bridge, December* 31, 1862.

The prevailing disease in the 4th Pennsylvania cavalry is diarrhœa. There is nothing in the climate or locality to cause it. It is due, I believe, to a lack of vegetable diet and the bad quality of the coffee, which doubtless is adulterated. The disease is readily controlled by opiates, but returns on the suspension of the remedy, as the cause is persistent.

Memorandum from the case-book of Surgeon WILLIAM O. MCDONALD, 27th Connecticut Volunteers. *Army of the Potomac, April*, 1863.

The cases of acute diarrhœa in the 27th Connecticut have usually been transient, and seemed best managed by a purge of blue mass, Epsom salts, or castor oil and laudanum, followed by light diet, and a small dose of opium after each passage. Many of the chronic cases, dating from as far back as the battle of Fredericksburg, December, 1862, would at times be much better, then worse again. Confirmed cases were worse after exercise or exposure on picket duty. Often they seemed to become used to the discharge, and its stoppage caused distress in the belly or rheumatic muscular pains. The passages as a rule were rather numerous, anywhere from four to twelve in the twenty-four hours; they were generally watery and light in color. The tongue was moist and clean, except when the general system became much affected, when it would be thinly furred or glazed. The

emaciation was not always very great, nor was the patient always much weakened; but the face invariably bore the impress of the disease. The abdomen was generally shrunken, and invariably tender in the umbilical region. The tenderness sometimes extended along the whole course of the colon, over the stomach, and into the hypogastrium; but the transverse colon was always tender. In one or two cases the spleen was sensitive to pressure. More or less pain ordinarily preceded the passages from the bowels. The urinary bladder was never sympathetically irritated. The appetite was craving, at times entirely beyond the patient's control, and in old cases it seemed to make but little difference what was eaten; that is, they were apparently no worse for indulgence. The liver was at times involved, jaundice supervening. These were the more obstinate cases, but were comparatively rare.

In the treatment of obstinate cases the use of iron has given the most satisfactory results, and the tincture of the chloride is probably the best form. It was administered in the dose of ten to fifteen drops, combined with an equal quantity of tincture of opium, three times daily. The recumbent position was insisted upon in bad cases, and no vegetables were allowed except potatoes and roasted apples; beef-tea, steak, &c., were given freely, unless specially contraindicated.

We have had but few cases, less than half a dozen, of dysentery, and these have been mild. The bloody discharges continued in no case over fifty hours. The bladder was not affected to any extent in these cases. Two ounces of salts given at once, as soon as the disease had manifested itself, would always render its subsequent cure easy. The salts caused frequent watery passages, and opium and abstinence rapidly caused these to cease.

Extract from the Report of Surgeon Francis C. Reamer, 143d Pennsylvania Volunteers. *Camp near Fort Slocum, D. C., quarter ending December* 31, 1863.

The 143d Pennsylvania was recruited in Luzerne county, Pennsylvania, and was mustered into service early in October, 1862. During the months of October and November, while still in camp in Luzerne county, an unusual number of cases of dyspepsia and diarrhœa were treated, which could be justly attributed to the new mode of living and the free use of indigestible food, such as badly baked pies, cakes, unripe fruit, and of fermented and alcoholic liquors. During the latter part of November we came to this place.

Extract from the Report of Surgeon William H. Thayer, 14th New Hampshire Volunteers, *to* Medical Inspector George W. Stipp, U. S. A. *Department of the Gulf, May* 4, 1864.

From November 1, 1862, to May 3, 1863, the 14th New Hampshire was on guard and picket duty in Maryland, along the Potomac from Edward's Ferry to Great Falls; subsequently, until January, 1864, it was on provost duty in and about Washington, D. C. During February it returned to Concord, New Hampshire, where it was furloughed, and subsequently went to New York, and thence by steamer to New Orleans, where we arrived April 12th.

During the six months we were in Maryland typhoid and typho-malarial fevers were very prevalent. We had also an epidemic of measles, and one of mumps. After we arrived in Washington the regiment enjoyed good health until midsummer, when the men began to suffer very much with diarrhœa, produced, as I believe, by the unwholesome atmosphere of the prisons where they were on duty as guards. Indeed diarrhœa has always been present in the regiment. During the first winter it was noticed that, besides the cases under treatment, a very large proportion of the officers and men on duty and otherwise well had habitually very loose dejections. In spite of this, all who were not seriously sick gained flesh very noticeably, from ten to fifteen pounds, during the winter.

Extract from the Report of Surgeon D. Wadsworth Wainwright, 4th New York Volunteers. *Havre de Grace, Maryland, quarter ending September* 30, 1861.

The 4th New York was stationed at Newport News, near Fortress Monroe, Virginia, from June 7th to July 20th. During this time the great majority of the sick were cases of acute diarrhœa and dysentery, of a mild type, yielding readily to treatment. The treatment, however, had to be changed at different times from calomel and opium to acetate of lead and opium, and afterward to castor oil and laudanum, for the reason that the other plans failed.

Some cases were peculiar in their nature; for instance, a man reported sick, with no marked symptoms of fever or great general or local derangement, still would waste away very rapidly, (one man lost twenty-five pounds in five days,) and pass quickly into a low typhoid state, evidently due to malarious influence. We had also a number of cases of chronic cephalalgia of malarious character, to which quinine gave the only relief.

Extract from the Report of Surgeon David Minis, jr., 48th Pennsylvania Volunteers. *Camp Winfield, North Carolina, quarter ending December* 31, 1861.

The 1st of October found the 48th Pennsylvania encamped at Camp Hamilton, near Fortress Monroe, and laboring under the usual epidemic of diarrhœa and dysentery to which new troops are liable. These diseases were at that time almost universal but manageable, no case terminating fatally. After their subsidence the health of the regiment was excellent, and continued so until the last week in October, when an epidemic of catarrh set in, having its origin in the exposure incident to the service during very inclement weather. This epidemic was also very general in its manifestations, and exceedingly painful in its symptoms, but readily yielding to treatment. During the first week in November typhoid fever made its appearance among us, following immediately in the footsteps of the epidemic catarrh, many of the cases of the latter appearing to glide by almost imperceptible gradations into a typhoid condition, with all the physical signs of the specific fever. On the 11th of November the regiment left Camp Hamilton, and on the 12th encamped at Fort Clark, near Hatteras Inlet. Immediately after our arrival numerous cases of typhoid fever, which had been in their incipiency on leaving Camp Hamilton, developed themselves fully, and being modified by the miasm of the island, assumed a malignant and unmanageable aspect, such as I had never witnessed

in any cases of the disease previously falling under my observation. In fact, in these cases typhoid fever, epidemic catarrh, remittent and intermittent fevers were so commingled and so complicated one another as to render the diagnosis very obscure, the treatment unsatisfactory, and the prognosis unfavorable. The most striking characteristic of this epidemic has been, in the graver cases, the almost total absence of tongue symptoms. In some cases which terminated fatally in a few days after the access of the disease there were no abnormal appearances of the tongue during the whole progress of the case; while those cases in which the tongue became heavily coated, dry, and red, made good recoveries. Between the 1st and 20th of December the regiment was moved from Fort Clark to Camp Winfield, about four miles north of Fort Clark. The general health of the command at present is good. Either from the prevalence of cool weather for the last two weeks, or because the troops are becoming acclimated, diseases having a malarious origin have almost disappeared. We have but few cases of severe aspect now under treatment. The men are here comfortably housed in barracks recently and well constructed for the purpose. The commissariat has generally furnished provisions abundantly and of good quality. The water here is not very palatable, and, being heavily loaded with vegetable matters, would doubtless, in warm weather, be a fruitful source of disease; but during the period of our occupancy of the island I have not been able to trace the origin of any case of disease to it.

Extract from the Report of Surgeon ALOIS D. GALL, 13th Indiana Volunteers. *Suffolk, Virginia, quarter ending September* 30, 1862.

During the first part of the quarter and up to the middle of August the 13th Indiana was stationed at Harrison's Landing. During this period the sick report was rather large, but the diseases were of a mild character, consisting chiefly of diarrhœa, dysentery, and cholera morbus. But one death occurred during this period, which was a case of typhoid fever.

On the 16th of August the regiment took up the line of march for Yorktown, where it encamped a few days, and on the 24th of August marched to Hampton. It was poorly supplied with rations and water during this movement, and did some hard marching. We remained about a week at Hampton, which gave us an opportunity to recuperate somewhat. The diseases which prevailed during the march were of the same character as previously mentioned. No cases of interest occurred, and none were fatal.

August 31st, we were ordered to Suffolk, Virginia. Since being here the sanitary condition has been pretty good, when we take into consideration the unfavorable influences which have surrounded us. We are encamped on the flat pine land between the marshy banks of the Nansemond river and the borders of the great Dismal Swamp, a region favorable to the prevalence of malarious diseases. But although malarious fevers have prevailed to a considerable extent since we have been stationed here, yet they have not been of a very severe type. No case of a congestive or malignant form has occurred, but we have had many mild cases of typho-malarial, intermittent, and remittent fevers. The mildness of these diseases can probably be attributed to the unusually small amount of rain which has fallen during the autumn. Dysentery has also prevailed in a mild form to a considerable extent, which no doubt depends to a great degree upon malarious influences as a predisposing cause. The water is very bad, having a little brackish, unpleasant taste, and generally containing a copious sediment. A third unfavorable influence is the severity of the labor the men had to perform during the past three weeks, felling timber and throwing up earth-works during the day, and being placed on picket duty all night, sometimes for several days and nights consecutively. The regiment is fully supplied with rations, and has a good supply of other food from the surrounding country; it is also abundantly well furnished with clothing and moderately supplied with tents.

Extract from the Report of Surgeon CHARLES C. JEWETT, 16th Massachusetts Volunteers, *to* Medical Inspector EDWARD P. VOLLUM, U. S. A. *Army of the Potomac, October* 20, 1862.

The 16th Massachusetts was stationed at Camp Hamilton, near Fortress Monroe, from September 1, 1861, to May 8, 1862. Subsequently we shared in the movements of the Army of the Potomac on the Peninsula, and in Virginia in front of Washington. While at Camp Hamilton we had a slight epidemic of measles, and about the same time one of mumps. These affections were mild and required but little treatment. Diarrhœa was very prevalent while on the Peninsula. Most of the cases yielded readily to a treatment consisting in saline laxatives at first, either alone or combined with a mercurial, and followed by an astringent and opiate course.

Extract from the Report of Surgeon JAMES WILSON, 99th New York Volunteers, *to* Medical Inspector WILLIAM H. MUSSEY. *Camp near Norfolk, Virginia, December*, 1862.

The diseases prevailing in the 99th New York at present are dysentery, intermittent fever, and diarrhœa. These are generally of the acute type and amenable to ordinary treatment. Far otherwise was a fatal type of dysentery which presented itself at Camp Greble, near Norfolk, in the latter part of September. In those cases the type was typhoid from the commencement. The discharges were abundant, of a reddish-brown or almost black color, and exceedingly offensive; the skin was cold and dusky, the tongue dark and dry, the teeth covered with sordes, and the pulse indicative of the greatest prostration. Fortunately only four of these cases occurred, three of them proving fatal; the fourth recovered under free stimulation.

Extract from the Report of the Inspection of the 3d New York Cavalry, by Medical Inspector WILLIAM H. MUSSEY, U. S. A. *Newbern, North Carolina, February* 27, 1863.

I found in the hospital of the 3d New York cavalry a case of colic which had existed three weeks without yielding to treatment. There was a broad blue line upon the edges of the gums, indicating lead poisoning. I found, on inquiry, that the patient had been treated for a long time previously with acetate of lead for dysentery. He had been taking fifteen grains of the acetate daily.

Extract from the Report of Assistant Surgeon GEORGE Z. BRETZ, 101st Pennsylvania Volunteers. *Camp near Long Bridge, Trent river, North Carolina, for the month of February*, 1863.

The 101st Pennsylvania has been encamped near Newbern, North Carolina, since December 21, 1862. We have suffered more or less all the time from diarrhœa and dysentery, apparently caused by miasmatic influences, imprudence in diet, lying on the ground, &c. The treatment has consisted in the use of cathartics, such as calomel and rhubarb, followed by opium combined with tannin, acetate of lead, prepared chalk, persulphate of iron, or subnitrate of bismuth; the latter is a favorite article.

Extract from the Report of Assistant Surgeon DIXI CROSBY HOYT, 5th Massachusetts Volunteers, *to* Medical Inspector WILLIAM H. MUSSEY, U. S. A. *Newbern, North Carolina, March* 6, 1863.

Since the 5th Massachusetts left home in October, 1862, catarrhs and acute and chronic diarrhœa have prevailed to quite an extent. The cases of acute diarrhœa have been characterized by discharges of thin, light-colored, feculent matter, mixed with blood, but not accompanied by great pain or tenesmus. The treatment has consisted in the administration of sulphate of magnesia combined with a little laudanum. The chronic form has been very common. The symptoms have been frequent and copious evacuations, with pain and nausea just before each discharge, thirst, and loss of appetite. In the treatment rest, light diet, and a combination of opium with vegetable or mineral astringents have been relied upon. The men have always suffered less from diarrhœa, and indeed also from colds and other affections, whilst marching or bivouacking, than when in more permanent camps.

Extract from the Report of Surgeon DAVID MERRITT, 55th Pennsylvania Volunteers. *Edisto Island, South Carolina, quarter ending June* 30, 1862.

The prevalent diseases during the quarter were bilious remittent fever, which was apt to assume a typhoid character, and dysentery. The latter was mild, of a bilious character, and easily managed by the prompt and energetic employment of calomel, followed by full doses of some saline cathartic, such as Epsom salts.

Extract from the Report of Surgeon JOSEPH L. MULFORD, 48*th* New York Volunteers. *Fort Pulaski, Georgia, August* 31, 1862.

The cases of fever this month have been of a mild form. The symptoms are nausea and vomiting, great lassitude and weakness, pain in the back part of the head, with a heaviness on top as of the weight of a stone, pain in the knees, high-colored urine, dark stools, slight pain in the liver. In all cases I think the difficulty arises from an inactive liver. The treatment in most cases has been twenty grains of calomel followed by castor oil, this followed by five grains of quinia dissolved in water by aromatic sulphuric acid, three times daily.

The cases of dysentery this month have also been of a mild form, yielding to the ordinary treatment of blue mass, followed by castor oil with a few drops of laudanum, after which the strength of the patient is supported with port-wine and quinine.

The cases of diarrhœa have been the most troublesome and difficult to handle, and in most instances result from an almost entire absence of vegetables. The rations in other respects have been good and well cooked; but too much fresh meat without vegetables has caused a large proportion of these cases.

Extract from the Report of Assistant Surgeon JACOB H. SCHEETZ, 47th Pennsylvania Volunteers. *Beaufort, South Carolina, August* 31, 1862.

Remittent fever has prevailed to a considerable extent. It was characterized by a daily exacerbation and remission. The greater number of those afflicted with it presented the following symptoms: A general feeling of lassitude for two or three days, with partial loss of appetite, followed by chills and flashes of heat alternately; cephalalgia, felt principally over the orbits, of a sharp lancinating character, sometimes, however, described as a dull, aching, heavy sensation. The eyes were most generally suffused, skin sallow, tongue coated, thirst, anorexia. The bowels in the greater number of cases were torpid, but in others disposed to looseness; there was tenderness over the right hypochondriac and epigastric regions, frequent nausea, and sometimes vomiting. The pulse ranged from 85 to 115 per minute. The skin was hot and dry during the exacerbations, moist and flaccid during the remissions. The urine was generally high colored, and caused frequent complaints of a scalding sensation while voiding it, and there was a continual complaint of pain in the back and extremities, &c. The treatment which was found most beneficial was to administer a mercurial purgative in cases in which the bowels were torpid; when there was nausea, twenty grains of ipecacuanha were combined with it. After the intestinal canal had been acted upon, five grains of quinine were given from four to six times daily. When there was diarrhœa, half a grain of opium or five of Dover's powder were given with each alternate dose. When the peculiar effects of the quinia were apparent the disease readily yielded. The epigastric tenderness, when severe, was treated with sinapisms and opiates. The diet was as light as possible.

Diarrhœa prevailed considerably. The cases were uniformly mild, unaccompanied by any febrile symptoms, and yielded to treatment very readily. The treatment consisted of vegetable astringents and opium, tannic acid and catechu being the astringents principally used.

Dysentery also assumed a mild type, very few cases presenting much febrile action. The treatment consisted in administering two grains of tartar emetic with half an ounce of Epsom salts, and following it with a combination of acetate of lead and opium, or more frequently two drachms of castor oil and forty drops of laudanum three times daily.

Extract from the Report of Surgeon William W. Brown, 7th New Hampshire Volunteers. *St. Augustine, Florida, quarter ending September* 30, 1862.

The 7th New Hampshire volunteers sailed from New York about the middle of February, 1862, and arrived at Fort Jefferson, Tortugas, Florida, on the 9th of March. About the middle of June we were ordered to Hilton Head, South Carolina, and encamped at Beaufort. When we arrived the weather was extremely hot and the atmosphere close and unpleasant. At Beaufort the sea breezes are cut off by the outside islands. Our encampment was under a beautiful shade of old live oaks. A general hospital had been established under the direction of Surgeon C. H. Crane, U. S. A., Medical Director of the Department of the South, and thither I was ordered to send all very sick men. Our men were rapidly attacked with bilious remittent fever. Our first cases were most severe, and typhoid symptoms came on early. Some twenty died during our first month at Beaufort. As the disease advanced it assumed a milder type. Nearly all the cases were attended with diarrhœa of a serous or bilious character, which was not easily controlled. Our treatment was at first an active mercurial cathartic, followed, when a remission occurred, with quinine in doses of ten grains. For the diarrhœa we gave a turpentine emulsion containing laudanum. We left Beaufort September 1st, and arrived at St. Augustine, Florida, on the 3d. Here the health of the regiment has evidently commenced to improve, though cases of fever similar to those we had at Beaufort still occur.

Extract from the Report of the same. St. Augustine, Florida, quarter ending December 31, 1862.

Since our arrival at this place, on the third of September last, the health of the regiment has rapidly improved, and no sickness of any severity, having its origin here, has occurred. For several weeks after our arrival, however, as mentioned in my last report, cases of fever similar to those we had at Beaufort continued to appear; but although some of these were severe, all recovered except one. During the last two months nothing of the kind has occurred. When we left Beaufort we had as many as one hundred and fifty men unfit for duty, about one-third of whom were left in general hospital at that place. Of these several have died; some were discharged and sent home; a small proportion recovered and returned to duty; others were sent here to join the regiment who still had chronic dysentery, and who have since died. With regard to this fatal disease I wish to be permitted to make a few concise observations: Camp dysentery has a malarial origin, and, no doubt, is primarily of a congestive character. At the onset it is often connected with remittent fever of a bilious variety. This fever in some cases assumes a typhoid character and frequently proves fatal within ten days; milder cases subside within that period, leaving the patient much prostrated and with the dysenteric symptoms unabated. The alvine evacuations are usually frequent, varying from three to twenty or more in the twenty-four hours. The discharges are only symptomatic of the lesion of the mucous surface of the large intestine. The matter discharged is by no means uniform in character. Sometimes it is serous or aqueous and very profuse for a day or two; then for awhile it consists of mucus intermixed with blood, and has a dark, grumous appearance; watery discharges tinged with blood and mixed with more or less fæcal matter of a very offensive character follow. Thus the patient goes on for weeks, constantly emaciating as the disease continues. He is inclined to take food after his fever subsides, and not unfrequently renders his condition worse by indulging his appetite too freely. Very little nutriment is taken into the circulation, no doubt owing in part to a diseased condition of the mesenteric glands.

During the last month of the disease, for its average duration is about four months, the stomach suffers exceedingly, and nearly everything is vomited. During the last week of life the mouth becomes aphthous, and deep sloughs sometimes form, from which a dark-colored sanious, very fetid fluid drains. These ulcerations of the mouth and throat often bleed freely, and sometimes to an alarming amount, notwithstanding the administration of the most powerful astringents. At this stage the evacuations are usually involuntary and of a most offensive character, filling the atmosphere in the neighborhood of the patient with a strongly marked gangrenous odor, and finally death is a welcome friend both to the patient and attendant.

In *post mortem* examinations I have not usually inspected the brain, and have generally found the heart and lungs healthy. The gall-bladder is full of thick viscid bile. The stomach always shows signs of inflammation; its blood-vessels are distended with blood, giving the mucous membrane a red color, especially near the pyloric extremity. In the small intestines also the mucous surface shows signs of inflammation, which probably does not take place before the last stage of the disease approaches. The chief seat of the disease is the large intestine; the peritoneal surface is unchanged in structure, but the mucous surface is only a mass of disease. We find the cæcum and every part of the colon and rectum much increased in weight and solidity, thickened, and in some parts the caliber so diminished as scarcely to admit the index finger, and within, throughout the whole length, numerous ulcerations, which are deepest where the weight of the intestine is greatest.

In the treatment it is found important at first to unload the portal system by a brisk mercurial cathartic or an emetic of ipecacuanha and tartarized antimony; then to give spirits of turpentine with mucilage and laudanum. A cautiously regulated diet is required, and quinine and occasionally stimulants are indicated by the symptoms. Absolute rest is of the greatest importance. I have also derived much benefit from dry cupping the epigastrium and abdomen, followed by bathing with turpentine lotions. Blistering the abdomen in many cases has had a most desirable effect. After the disease has continued some time recoveries are rare; yet by great attention to diet and regimen even extreme cases get well. I have made a thorough trial of the acetate of lead combined with opium, and of tannic acid with anodynes, but without good results. Nitrate of silver has acted well in some cases, but cannot be relied upon as a rule. I have also tried strychnine and Fowler's solution, but only to be disappointed. In the advanced stages great benefit has been derived from the free use of tincture of chloride of iron and brandy, with opiates and a simple nourishing diet.

Extract from the Report of Surgeon David Merritt, 55th Pennsylvania Volunteers. *Beaufort, South Carolina, quarter ending December* 31, 1862.

We had many cases of intermittent fever which were generally mild in character. One of their most prominent complications was a periodical congestion of the bowels, simulating acute dysentery both in the frequency of the discharges and in the

fact that they often consisted of mingled mucus and blood. This appears to be the species of dysentery described by Eberle in his Practice of Medicine as prevailing at times in the valley of the Mississippi. In the treatment of such cases I found quinine advantageous. Sometimes I used no other medication, and when the paroxysms were cut short, I generally found the bowels became regular and the passages normal in character. In other cases the careful use of astringents, besides the quinine, seemed demanded.

Extract from the Report of the same to Medical Inspector William H. Mussey, U. S. A. *Beaufort, South Carolina, May* 10, 1863.

The 55th Pennsylvania reached Hilton Head December 11, 1861, and has been in the department of the South ever since. Acute diarrhœa has been very prevalent in the regiment; I believe the bad quality of the drinking water was generally the principal cause. Whenever this was the case a combination of tannic acid, camphor, and opium was the most successful mode of treatment. When the diarrhœa was of a miasmatic origin, quinine was of course associated with whatever medicines were employed. We have also had considerable chronic diarrhœa, which resisted almost every plan of treatment, so that it was generally thought best to send the patients to general hospital. In the cases treated in camp, astringents proved of little advantage. It is better to promote the secretion of the liver, to act upon the skin and kidneys, and to give unirritating nourishing food. Quinine and Fowler's solution have also been given with advantage, and nitrate of silver or creasote when ulceration of the bowels has been suspected. But in fact the disease in this climate often seems to baffle all treatment, and the best plan is to send chronic cases to the north.

Extract from the Report of Surgeon B. F. Harrison, Independent Battalion New York Volunteers, *to* Medical Inspector William H. Mussey, U. S. A. *Beaufort, South Carolina, May* 21, 1863.

The prevailing diseases have been intermittent fever, diarrhœa, and dysentery. The last two diseases, so long as they were functional, were for the most part managed with ease. The diarrhœa yielded to rhubarb or magnesia, with some simple bitters and aromatics, such as calumbo and ginger or cinnamon. The dysentery, when there was no ulceration, was successfully treated with an ounce of sulphate of magnesia and quarter of a grain of morphine. When this was followed up with the treatment for diarrhœa, it was usually sufficient; but when ulceration occurred the cases were more difficult to manage, and during the autumn we had a number that baffled all our efforts. In two or three of these in which *post mortem* examinations were made the ulcerative destruction of the rectum and colon was remarkable. In one case not more than one-twentieth of the mucous membrane remained intact in the rectum and lower part of the colon. There was, moreover, much thickening of the walls of the intestines, so that they felt like India-rubber tubes of the same size and about a quarter of an inch in thickness. Some of the ulcers were so deep that they appeared nearly to perforate the intestines, and in one case we could not determine if the perforation was complete or whether the tissues had merely broken in the dissection. In no case of dysentery which we examined did ulceration exist in the small intestine.

It may be inquired how cases of functional dysentery can be distinguished from the structural or ulcerative cases. When the ordinary remedies only produced partial relief it was safe to infer that the tissues were already involved. Often in the later stages purulent matter of the character yielded by scrofulous ulcers was seen in the stools, as also débris of the mucous membrane mingled with blood; but such matters did not usually make their appearance until the general symptoms left little room to doubt. There was sometimes tenderness of the abdomen on pressure, and sometimes none at all, from the beginning to the end of the case; but in every case the abdomen was shrunken, the intestines seeming to be packed away in the pelvis and by the side of the spine, so that the anterior wall of the abdomen receded to the spine.

In the treatment of dysentery we used injections of nitrate of silver in solution a few times, but it answered my expectations so litttle that I soon discontinued its use. I only used six or eight grains to the ounce. From what I have learned from others, however, I would employ it again under similar circumstances, using fifteen or twenty grains to the ounce. We thought the cases in which ulceration had taken place did best with low diet, mild astringents, and bitter tonics.

Extract from the Report of Surgeon Samuel F. Forbes, 67th Ohio Volunteers, *to* Medical Inspector William H. Mussey, U. S. A. *Folly Island, South Carolina, May*, 1863.

The 67th Ohio was recruited chiefly at Camp Oliver, Toledo, Ohio. It moved to Camp Chase, Columbus, Ohio, December 24, 1861, and set out for western Virginia January 19, 1862. It subsequently became a part of the division of General Shields; was sent to join General McClellan at Harrison's Landing, arriving there July 2d; thence went to Suffolk, Virginia, where it remained from September 1st to the end of the year. It was then sent to North Carolina, and afterward to South Carolina, arriving at Port Royal February 8th, and moved to its present camp at Folly Island April 13th. Our camp here is a narrow bed of sand, with the ocean on one side and a creek and marshes on the other. The weather is generally very warm in the fore part of the day, but the latter part is quite delightful from the fine ocean breezes. The drinking water is very bad, and is doubtless the cause of much of the diarrhœa which prevails. Typhoid fever and dysentery have also prevailed in the regiment, arising, I think, from the confinement of our late sea voyage, and the fact that the ports of the Collins took in water and the men were obliged to lie on the wet floors, as there were no bunks for them. The dysentery has probably been aggravated by the warm days and cold nights, the bad water, and the want of vegetable food.

In the treatment of these cases, both here and previously, we have been quite successful, not having lost a case out of seven hundred and seventy-five occurring since we went into the field. The plan has been to administer gentle laxatives of castor oil or of a saline mixture, alternated with opiates every other day. We had an epidemic of measles in January, 1862, which broke out at Camp Necessity, on the Baltimore and Ohio railroad, and continued, while the regiment was at New Creek

and Paw-Paw tunnel, during the month of February and the early part of March. In all there were ninety-three cases, of which nine died with the regiment, and over seventy were sent to general hospital at Cumberland, of whom I am informed a number died. We had also an epidemic of mumps while at Paw-Paw tunnel.

Extract from the Report of Surgeon CHARLES H. HOOD, 62d Ohio Volunteers. *Camp near Strasburg, Virginia, quarter ending March* 31, 1862.

The 62d Ohio suffered from measles during January. It arrived at camp Kelley, Maryland, January 20, 1862. Diarrhœa and pulmonary catarrh soon became prevalent, from seventy-five to ninety men presenting themselves daily at sick-call. The diarrhœa cases were often troublesome, and in many instances presented well-marked dysenteric symptoms, and while the patients continued to use the water in and around the camp we found our remedial measures almost entirely unavailing, while a strict abstinence from all liquids, and especially from the water around us, with suitable aperients and tonics, were very effectual in completely curing the disease.

Extract from the Report of Surgeon JOSEPH B. POTTER, 30th Ohio Volunteers. *Fayetteville, western Virginia, quarter ending March* 31, 1862.

The prevalent diseases during this quarter have been fevers, diarrhœa, jaundice, and catarrhs. These diseases have prevailed among the citizens in about equal proportions and severity as with the troops. The fever classed as typhoid is not the disease so recognized by most physicians in private practice, but a continued fever of typhoid type, modified by change of habits, food, and to a certain extent climate. Many cases when first reported are found delirious, with cold extremities, congestion of the capillaries of the surface, profuse perspiration, pulse 120 to 160 per minute and feeble, profuse watery diarrhœa, followed by a fatal termination in from forty-eight to seventy-two hours. All these cases require stimulants, as quinia, carbonate of ammonia, brandy, &c., from the commencement of treatment. Intermittent fevers have been mild in character, and readily amenable to treatment.

Diarrhœa during January was almost universal; scarcely a person was exempt. Cases gradually became of milder character during February and March. The treatment found to be of most service was opiates in combination with astringents and stimulants, and occasional saline cathartics; mercurials were almost universally injurious. Jaundice was prevalent in January and February, but has now entirely disappeared.

Extract from the Report of Surgeon HENRY K. STEELE, 44th Ohio Volunteers. *Camp Meadow Bluff, western Virginia, June* 30, 1862.

We have suffered very much during the past month from diarrhœa and dysentery, and an epidemic of measles is commencing. The first two diseases I attribute to the drinking water, which is so much charged with vegetable matter as to be unpleasant to the taste. It is surface water, and we are dependent upon the frequent rains for our supply. We are encamped in the woods, surrounded on all sides by marshes, and have no tents.

Extract from the Report of Surgeon JAMES K. BIGELOW, 8th Indiana Volunteers, *to* Medical Inspector GEORGE W. STIPP. *Department of the Gulf, February* 20, 1864.

The 8th Indiana was mustered in at Indianapolis, Indiana, September 5, 1861. It had previously served as a three-months' regiment in western Virginia. Subsequently, until March, 1863, it campaigned in Missouri and Arkansas. Afterward it took part in the operations against Vicksburg, was transferred to Carrolton, Louisiana, in August, 1863, and is now at Indianola, Texas. During the time it was in western Virginia the prevailing disease was a mild form of dysentery, which generally resulted favorably. During the autumn of 1861 we had an epidemic of measles; with this exception diarrhœa and dysentery have been at all times the most prevalent diseases.

Dysentery made its appearance first at Georgetown, Missouri, about the last of September, 1861, and assumed huge proportions at the outset. In our regiment, which then numbered about seven hundred and fifty or eight hundred men, we had a morning sick report averaging about one hundred and seventy-five cases daily. The symptoms were not different from ordinary dysentery, except that the disease was ushered in much more speedily than usual. A soldier, seemingly well in the morning, would frequently have well-developed dysentery the same day. I may state, too, that the usual nervous prostration attendant on that disease was not so well marked during this epidemic; it seemed, indeed, in the majority of cases to disturb the constitution but slightly. The soldiers were nearly all treated in their quarters, because so many cases could not be provided with hospital accommodations, and they were usually able to attend sick-call notwithstanding the pain, tenesmus, muco-sanguineous discharges, and other symptoms of acute dysentery. In the treatment vegetable astringents and dietetic measures were tried at first, but without avail; then we resorted to the mineral astringents, such as nitrate of silver, sulphate of iron, acetate of lead, &c., without other effect than to cause occasional mischief with the lead, probably owing to the chemical condition of the water of that region. Sulphate of magnesia or rhubarb, followed by opium and quinine, with dietetic and hygienic measures, were finally relied upon, and usually with prompt success.

Extract from the Report of Surgeon GEORGE L. LUCAS, 47th Illinois Volunteers. *Jefferson City, Missouri, quarter ending December* 31, 1861.

The 47th Illinois was organized at Peoria, Illinois, last August. Less than half the men came from the high prairie region, the others from the flat prairies where miasmatic influences prevail. While at Peoria the prevailing diseases were diarrhœa and intermittent fever. We arrived at Camp Benton, near St. Louis, Missouri, September 22d, and at Jefferson City October 10th. We still continue to suffer from intermittents and diarrhœa, but to these typhoid fever has been superadded.

Extract from the Report of Surgeon J. R. VEETER, 2d Missouri Volunteers. *Camp near Rolla, Missouri, quarter ending December* 31, 1861.

The most prevalent diseases in the 2d Missouri during the past quarter were quotidian and tertian intermittents, diarrhœas, and dysenteries. These are due, as I think, partly to the atmospheric influences of the autumnal season during our movements through parts of the country where these diseases are prevalent every year, and partly to the exhaustion of our soldiers, who have been compelled to move by forced marches, sleeping on the bare ground protected at night by only a single blanket, and often having wet shoes from crossing creeks and rivers. The diet also was bad; at times for days together the soldiers had nothing but fresh meat, either beef or pork, without salt, and no bread or vegetables could be obtained.

Extract from the Report of Assistant Surgeon J. C. G. HAPPERSETT, U. S. A., 1st United States Infantry. *Camp near New Madrid, Missouri, quarter ending March* 31, 1862.

Before the evacuation of New Madrid by the enemy, and while wells were being dug, the men used the water from the pools in the neighborhood of their camp for drinking purposes. This was followed by the most intractable diarrhœas. The companies suffering most were those who joined us at St. Louis, and who were just from Key West, Florida.

Extract from the Report of Surgeon CLARKE G. PEASE, 2d Wisconsin Cavalry. *Cassville, Missouri, quarter ending June* 30, 1862.

Early in April, while the 2d Wisconsin cavalry was at Benton Barracks, the influence of the water of the Mississippi began to manifest itself by the development of frequent cases of diarrhœa. After we reached Jefferson City, the water of the Missouri proved still worse, and within a few days after our arrival at that place a number of cases of great severity occurred. The water of the country lying between the Missouri and the Osage is highly impregnated with magnesia. The weather, during our march across the country, was warm, and the men drank largely; as the result of this, many cases of diarrhœa occurred, some of which have been very intractable.

Extract from the Report of the same. Springfield, Missouri, quarter ending September 30, 1862.

During the extreme heat of July diarrhœa was very prevalent, and often severe; very little dysentery, however, occurred. Jaundice in all its varieties, and in some cases of great severity, has been common, and under circumstances which have led me to believe that food rather than climate has been the exciting cause. Sudden changes from soft bread and fresh meat to an exclusive diet of hard bread and salted meats, or the reverse of this, have invariably been followed by an increase of the number of cases of diarrhœa and jaundice. Indeed, I am of the opinion that hard bread, used as it is by most of the soldiers in this army, is a potent cause of diarrhœa and of numerous cases of dyspepsia, which prove wellnigh incurable. This battalion has been much employed in scouting, and consequently has been much exposed to the weather and to great fatigue; but I have observed that fewer men are taken sick, in a given time, while on a scout than while lying in camp. Idleness and the atmosphere of the camp are the most prolific sources of disease.

Extract from the Report of Surgeon HENRY P. STRONG, 11th Wisconsin Volunteers. *Camp near Des Arc, Arkansas, quarter ending June* 30, 1862.

During the greater part of the quarter the 11th Wisconsin has been on the march through the States of Missouri and Arkansas, most of the time in swampy and miasmatic regions. The days have been hot, the nights cold. I was a little surprised, during the latter part of May, to notice scorbutic symptoms in several cases, for a fair proportion of fresh meat and desiccated vegetables had been issued to the men. There have been no cases of fully developed scurvy, and I have not observed sponginess of the gums in a single case; but in several I have observed spots of purpura on the legs or body, and in some of the cases of dysentery and of remittent fevers, hæmorrhages from the nose or fauces. Most of the cases of dysentery have been bilious or remittent in character, and exhibit a strong tendency to become chronic. In the treatment I have found astringents worse than useless in most cases. The plan of first evacuating the bowels thoroughly and then arresting the peristaltic action by an opiate has proved the most successful; but, in the cases which came under my observation, mercurials have proved more efficient than saline cathartics.

Extract from the Report of Surgeon BENONI O. REYNOLDS, 3d Wisconsin Cavalry. *Cassville, Missouri, July*, 1862.

Mild intermittents and remittents have prevailed to some extent during the month, and there have been many slight cases of diarrhœa, which were, for the most part, successfully treated in quarters with opium and camphor. Dysentery also prevailed to some extent, but has been of a very mild character. When a patient presented himself with symptoms of this disease, I usually directed an ounce of sulphate of magnesia, and, after the free evacuation of the bowels, gave opium in grain doses every three or four hours until two or more doses had been taken. Generally no other medicines were required.

Extract from the Report of the same. Leavenworth, Kansas, quarter ending September 30, 1862.

Many cases of diarrhœa and dysentery have been treated during the quarter. With regard to the treatment of the latter disease I take pleasure in adding my testimony to the efficiency of what is termed the saline treatment. Our cases have almost invariably yielded to a large dose of sulphate of magnesia, followed, after free catharsis, by one or two-grain doses of opium.

Extract from the Report of Assistant Surgeon GEORGE C. JONES, 3d Missouri Cavalry. *Rolla, Missouri, July and August,* 1862.

Diarrhœa and dysentery prevailed to a considerable extent in the 3d Missouri cavalry from shortly after its arrival in Rolla, June 20th, until the close of July, with comparatively few cases of malarial fever. The cases of diarrhœa showed a disposition to run into a more inflammatory grade of disease in the large intestine if neglected for a few days.

The diarrhœa, when severe, was attended with much griping in the bowels, and considerable headache and pain in the back. The arrest of the discharge, when attempted by opium or other means, almost invariably had the effect to increase the pain in the bowels, head, and back, and it became necessary nearly always, when such a result was obtained, to administer a purgative. Nevertheless, opium, in some of its forms, was much relied on in the treatment, especially when the diet of the patient could be controlled so that no ingesta should be received into the stomach which would be likely to irritate the already irritated mucous membrane; it was usually sufficient for the cure, but occasionally required to be combined with some vegetable or mineral astringent. Considering the slight control we can have over the habits of men in camp in regard to eating, few cases of diarrhœa merged into dysentery, and the number of primary cases of dysentery was not large. Those which occurred were characterized by frequent and bloody discharges from the bowels, with a great deal of tormina, tenesmus, and abdominal soreness. The circulation was invariably more or less disturbed, the grade of the fever being generally in proportion to the degree of inflammatory irritation present.

The treatment consisted in a purgative of castor oil or of calomel, followed by sulphate of magnesia when portal congestion was suspected; this was followed by anodynes in the form of opium or Dover's powder, to relieve pain and restrain peristaltic action. In addition to this internal treatment, local measures were addressed to the abdominal parietes, such as sinapisms, turpentine stupes, and dry or wet cups. The latter were never omitted when the case assumed an aspect at all threatening, and were uniformly beneficial. Injections of cold water and laudanum, to restrain tenesmus, were likewise found to afford great relief. The constitutional action of mercury was not required in a single case.

During the month of August there was a notable increase in the number of cases of fever of a remittent and intermittent type, with a sensible diminution of the cases of diarrhœa and dysentery.

Extract from the Report of Surgeon JOHN W. SCOTT, 10th Kansas Volunteers. *Department of Missouri, quarter ending September* 30, 1862.

During the month of July the 10th Kansas was in the Cherokee country, and scorbutic symptoms appeared among the men, owing to the lack of fresh vegetables. A supply of desiccated vegetables having been obtained, these symptoms disappeared. Throughout the quarter there was a large number of cases of simple diarrhœa, caused by irregularities in diet and sudden changes in the temperature and hygrometrical condition of the atmosphere. We had also many cases of malarious fever, the remittent type prevailing; a few of the cases assumed a typhoid form.

Extract from the Report of Surgeon WILLIAM H. WHITE, 22d Iowa Volunteers. *Post hospital, Rolla, Missouri, for the month of November,* 1862.

The cases of dysentery received into this hospital during the month were, many of them, severe. They presented no remarkable symptoms except that the discharges contained rather more blood than is commonly seen, and that there was an unusual tendency to sinking. In the treatment, calomel combined with some of the alkalies, diaphoretics, opium, and astringents have been employed, with frequent injections of nitrate of silver or iodine, as in the following formulæ: ℞. Nitrate of silver eight grains, water two ounces; or, ℞. Iodine and iodide of potassium, of each ten grains, sulphate of morphia half a grain, water three ounces. After the injection of either of these solutions there would seldom be another stool in less than two or three hours, even when they had previously been occurring every few minutes. At the same time a large blister was applied over the abdomen, and good beef-tea or rich chicken-broth allowed. The success of this plan of treatment has been entirely satisfactory.

Anasarca has followed many of these cases of dysentery, as well as those of chronic diarrhœa and typhoid fever. It has generally subsided under the influence of iron and tonics. In some cases friction with a stimulating liniment has appeared to be a useful addition to the treatment.

Extract from the Report of Surgeon ANDREW W. MCCLURE, 4th Iowa Cavalry. *Camp near Helena, Arkansas, quarter ending December* 31, 1862.

Diarrhœa and dysentery, aggravated by the malarious atmosphere of this region and by improper diet, have contributed their share towards thinning our ranks. The saline treatment, with opium, has succeeded better in my hands than any other remedies in this class of cases.

Extract from the Report of Assistant Surgeon WILLIAM W. GRANGER, 3d Missouri Cavalry. *Houston, Missouri, December* 31, 1862.

Diarrhœa and dysentery have been very troublesome, and many of the cases have become chronic. The obstinacy with which, at times, these complaints resist all treatment, and even after an apparent cure return on the slightest exposure or unavoidable irregularity in diet, is truly trying. Alteratives, tonics, especially the mineral acids, and preparations of iron and vegetable astringents, have afforded me the best results in the majority of cases. I have also found quinine of great benefit in some instances which could be traced back to a malarious origin. Rest, regularity, temperance, and proper selection of diet are also indispensable. As winter advances the number of cases is diminished, and perhaps the dear-bought experience of the past year may be of service to us next summer. In acute dysentery I have been most successful so far in using opiates to allay the tormina, while free evacuations of the colon have been induced by bland injections of tepid water or starch-water. After filling and emptying the colon once or twice, I give a two-ounce injection of water containing ten grains of nitrate of silver with a drachm of laudanum. This is repeated once, twice, or oftener during the day. Next to this plan, and many good surgeons prefer it, I rank the repeated administration of saline purgatives till free watery discharges are procured; meanwhile, and for twenty-four hours after, nearly all fluids should be withheld from the patient.

Acute diarrhœa has generally demanded a different and longer course of treatment. The mucous and serous forms have very generally yielded readily to a brisk mercurial purgative followed by opiates and astringents. If, within twenty-four hours after purgation, the discharges were not so modified in frequency and character as to indicate convalescence, I have sometimes repeated the mercurial purge, or prescribed quarter-grain doses of calomel, combined with the opiates and astringents. These small doses I seldom continue more than a day or so, after which the opiates and astringents are continued. In the sanguineous form of diarrhœa I have found saline purgatives, pushed till free watery discharges ensue, and followed by anodynes and astringents, with blue mass in two-grain doses on alternate days, the most satisfactory mode of treatment.

Extract from the Report of Surgeon ALLEN F. PECK, 1st New Mexico Volunteers. *Fort Stanton, New Mexico, quarter ending December* 31, 1862.

Many of the cases of diarrhœa and dysentery were caused by intemperance in some form, although the weather has been such as to favor the production of this class of diseases, the days having been quite warm and the nights cold.

In the treatment of diarrhœa I find half an ounce of castor oil with half a drachm of oil of turpentine, administered at once, produces very happy results; and half an ounce of sulphate of magnesia, with mucilaginous drinks and a bland diet, answered very well in the cases of dysentery. In cases of either disease which were not checked by these simple remedies, I used small doses of some mercurial, or acetate of lead, combined with enough Dover's powder or opium to quiet pain.

Extract from the Report of Surgeon WILLIAM H. GRIMES, 13th Kansas Volunteers. *Camp near Springfield, Missouri, January* 31, 1863.

A number of cases of dysentery and diarrhœa occurred during January. Both these diseases have prevailed, to a greater or less extent, ever since the 13th Kansas has been in the field. Neither officers nor men are exempt. I attribute both disorders to imprudences in diet, which always characterize new recruits, and to drinking surface water. Many of the cases have been obstinate; there were, however, but few deaths. The treatment which seemed most successful was a purge of Epsom salts, followed by astringents such as tannin, acetate of lead, &c., combined with opium. The use of cold water by the sick was prevented, as far as practicable, as we always found it aggravated the symptoms.

Extract from the Report of Surgeon BENJAMIN F. STEVENSON, 22d Kentucky Volunteers. *On board the steamboat Crescent City, near Vicksburg, Mississippi, January* 9, 1863.

We left Portland, Ohio, October 20th, crossed the Ohio river at Gallipolis on the 22d, and reached Charlestown, West Virginia, on the 28th. While at Charlestown a marked increase in the number of diarrhœa cases was observed. This was in part due, no doubt, to errors of diet; but, in my judgment, a much more fruitful source both of diarrhœa and dysentery is to be found in disturbances of the functions of the skin. The soldier is often compelled to lie on the wet ground in damp clothes and in a wet blanket; the surface is chilled, and the fluids, repelled from the integument, are precipitated upon the mucous membranes. The intestinal canal, already disordered by injudicious alimentation, is particularly liable to suffer under these circumstances.

Extract from the Report of Surgeon JOHN L. TAYLOR, 3d Missouri Cavalry. *Little Rock, Arkansas, June* 30, 1864.

Dysenteric diarrhœa occurred to a considerable extent in the 3d Missouri cavalry during the month of June. The mean strength of the command was one thousand, and there were fifty cases during the month. In these cases, at the outset, the stools were composed chiefly of unnaturally fluid fæcal matter mingled with blood and mucus. The majority of cases ran their course with very little disturbance of the circulation, and yielded readily to saline cathartics. The tenesmus was greatly alleviated by mucilaginous and anodyne enemata. In the administration of Epsom salts we have in view the production of one or more watery alvine discharges, that the portal vessels may be unloaded and all crude ingesta removed from the alimentary canal.

The patient found in almost every instance a soothing and comfortable effect when watery discharges were produced. After this, enemata of warm starch-water with laudanum allayed the distress, and a rapid convalescence followed, without repeating the salts.

Four-fifths of the cases were attributable to exposure to wet and cold; the remaining fifth to malaria and the use of unwholesome food, such as fresh pork, green apples, &c. Five cases were attended with more or less fever, which was attributable, no doubt, to malarious poison. These cases I have denominated on the prescription book "malarial dysenteric diarrhœa." The fever in these cases began before the local symptoms declared themselves. The fever ran high, the pulse was hard and frequent, the skin hot, the face flushed, the tongue furred, and the patient complained of headache and thirst. The pulse very soon became small and weak, while the strength rapidly declined and the temperature of the body sank. With these patients there existed also an enlarged spleen.

I have found that nitric acid combined with ipecacuanha successfully met this condition. I have always been satisfied that these remedial agents, separately, exercised a decided influence on the liver; the combination proves a more valuable hepatic remedy than when the medicines are given alone. I gave four drops of nitric acid with four grains of ipecacuanha in a fluid ounce of water every four to six hours. In the treatment of ordinary cases, in addition to saline cathartics, wet cupping upon that portion of the abdomen where pressure caused the most pain, mucilaginous anodyne injections, and turpentine stupes are advantageous. So soon as the bowels are thoroughly emptied, five grains of quinine with ten of Dover's powder may be given three or four times daily, and continued so long as fever exists. In the malarious cases quinine proves very efficient, the more obstinate cases giving way in from four to six days. The patients were then treated with tincture of the chloride of iron, which seemed to obviate the tendency to repeated attacks. In some patients tenesmus remains after the more prominent symptoms of the disease have been removed. Usually this condition is dependent upon ulceration low down in the rectum. Injections of two fluid drachms of tincture of the chloride of iron in an ounce of water three times daily, or *pro re nata*, have afforded prompt relief in nearly every case. * * *

While my experience sustains the success of saline purgatives in the commencement of dysentery and diarrhœa, it equally sustains the fact that a too frequent repetition of this purgative, as advocated by some for the purpose of procuring natural stools, in nearly every case increases the irritation of the bowels and augments considerably the suffering of the patient. It is unquestionably true that when ulceration of the intestines exists purgatives are inadmissible. In this condition I have found from four to six drops of Fowler's solution daily an efficient remedy. It answers a better purpose than the alternate use of laxatives, opiates, and astringents. * * *

Extract from the Report of Acting Assistant Surgeon J. D. Skeer. *Camp of the 16th United States Infantry, near Chicago, Illinois, September*, 1861.

The camp of the 16th infantry, on the Oplain river, sixteen miles northwest of Chicago, is bounded on the east and north by a marsh. This circumstance accounts for the large number of cases of ague and diarrhœa among our men during the month, most of the latter being of a decidedly bilious character, having well-marked remissions and exacerbations, and requiring the use of antiperiodic medicines. Sulphate of quinia has been chiefly used for this purpose.

Extract from the Report of Assistant Surgeon Havilah M. Sprague, U. S. A. *Alton, Illinois, March* 31, 1862.

The battalion of the 13th U. S. infantry at this post is on duty as guard to the prisoners of war. I joined the command December 25th, and found the men suffering from an epidemic of measles. The cases were mild, and none of them were followed by pneumonia; but bronchitis, with marked debility, was left behind in many cases, and in a few (chiefly feeble young men of phthisical families) tuberculosis was developed. Mumps subsequently made its appearance and went through the battalion. It has been very mild, requiring no treatment except in a few cases in which metastasis to the testicles took place. About the first of March a great number of cases of diarrhœa appeared. They were usually quite simple. The discharges were usually yellowish and watery, sometimes ashy, black, or greenish. They were attended with colicky pains and slight tenderness of the bowels; usually there was no febrile reaction. In a very few cases it terminated in mild dysentery. In quite a proportion it has shown a tendency to become chronic, and considerable difficulty has been experienced in checking it permanently.

Extract from the Report of Surgeon Thomas G. Cleveland, 41st Ohio Volunteers. *Camp Wood, Ohio, September* 30, 1861.

The chief diseases during the month of September were diarrhœa and dysentery. Most of the cases occurred at two distinct periods, each lasting four or five days and then subsiding, from which it would appear the cause was atmospheric. The weather at these times was warm and clear during the day, but the nights were cold, the variation in temperature from day to night being very considerable. The men, having only one blanket apiece, were indifferently protected from these changes, and as there was a short allowance of tents they were so crowded that many slept in the open air. Many cases of subacute rheumatism appear to have been due to the same cause. Moreover, the influence of malarial poisoning is seen in many cases assuming a great variety of irregular forms, though with comparatively few cases of clearly defined intermittent fever.

Extract from the Report of Surgeon Roswell G. Bogue, 19th Illinois Volunteers. *Camp Jefferson, Kentucky, quarter ending December* 31, 1861.

During the last summer and early fall the 19th Illinois operated in highly malarious districts, which caused a great deal of intermittent fever and diarrhœa, the effects of which have continued to influence the diseases of the men until the present time.

Extract from the Report of Surgeon Claiborne J. Walton, 21st Kentucky Volunteers. *Camp Fry, Adair County, Kentucky, quarter ending March* 31, 1862.

The 21st Kentucky was composed in part of recruits from Lexington, Kentucky, and the surrounding country, and of about an equal number from the Green river region. The latter, with few exceptions, had never had measles, and that disease broke out in November, 1861, and a large number of cases occurred. The mortality was small, but the patients were left in a debilitated condition, and coughs and colds were common for a long time after. However, the only diseases which gave us much trouble were diarrhœa and typhoid fever.

We had during the quarter two hundred and twelve cases of diarrhœa, most of which were very stubborn. To this number we might add a great many cases which were not recorded and only required a dose or two of opium to relieve them. The principal causes of diarrhœa were doubtless the manner in which the soldiers did their cooking, and sleeping in damp tents with but little straw, eight or ten crowded into a small bell-tent. All the cases were accompanied by considerable constitutional depression. The treatment was opium, tannin, acetate of lead, and turpentine. In stubborn cases I gave a grain of opium and quarter of a grain of sulphate of copper three times daily. When they seemed likely to become chronic I gave a grain of opium and quarter of a grain of nitrate of silver three times daily. To patients who were very weak and debilitated I sometimes gave, with very decided benefit, a grain each of opium and persulphate of iron, with three of camphor. A few very difficult cases were benefitted by the use of aromatic sulphuric acid in ten-drop doses three times daily. Quite a number of the cases occurred in those who had had measles. I saw some cases that presented a most unfavorable appearance cured by a liberal dose or two of opium.

Extract from the Report of Surgeon Edward L. Hill, 20th Ohio Volunteers. *Crump's Landing, Tennessee, quarter ending March* 31, 1862.

The 20th Ohio left Cincinnati on transports February 11, 1862, for Fort Donelson, and participated in the siege. Subsequently it was sent as an escort of prisoners of war to St. Louis, Missouri; after which two companies were sent with prisoners to Camp Douglas, Illinois, two to Indianapolis, Indiana, and three to Columbus, Ohio; one of the latter companies afterward went to Boston, Massachusetts. March 5th, the able-bodied men of six companies rendezvoused at St. Louis and started for the Tennessee river.

After the siege of Fort Donelson diarrhœa was the prevailing disease. It attacked all the detachments alike, whether at St. Louis, Indianapolis, Columbus, or Boston. It was of a typhoid type, attended with debility and great prostration, requiring tonics and stimulants in addition to the ordinary treatment, and often difficult to cure. If in this debilitated condition one took cold, and all seemed peculiarly susceptible to atmospheric changes and the ordinary causes producing colds, he was almost sure to have pneumonia, which early assumed a typhoid type and proved very fatal.

While on the steamboat going up the Tennessee river diarrhœa became still more general, and after landing, though we had a pleasant camp and an abundant supply of tolerably good water, there was no improvement. Dejection, depression of spirits, listlessness, and melancholy prevailed among the men.

Extract from the Report of Surgeon Shubal York, 54th Illinois Volunteers. *Jackson, Tennessee, quarter ending March* 31, 1862.

The fevers which prevailed during the quarter among the men of the 54th Illinois have been chiefly intermittents and remittents, which readily yielded to treatment, but very often relapsed. It should be mentioned that all last summer and autumn the regiment was exposed to the influence of malaria in the low lands of Tennessee, and most of them had attacks of intermittent or remittent fever at that time. Diarrhœa and dysentery prevailed to a moderate extent during the quarter; they were of an asthenic form, but yielded readily to mild alterative and anodyne measures.

Extract from the Report of Assistant Surgeon Dallas Bache, U. S. A. *Camp near Stevenson, Alabama, quarter ending June* 30, 1862.

Battery H, 5th artillery, U. S. A., was occupied during the months of April and May in slow approaches from Pittsburg Landing to Corinth, Mississippi, and, since the capture of Corinth, a constant drought and the character of the surface water obliged the troops to resort to such wells as they could dig for the necessary supply. This was a prolific source of diarrhœa, complicated with malaria, and made doubly obstinate by the scorbutic taint induced by want of vegetables and the monotonous character of the food.

Extract from the Report of Surgeon John C. Hubbard, 41st Ohio Volunteers. *Athens, Alabama, quarter ending June* 30, 1862.

After the siege of Corinth the 41st Ohio marched through northern Mississippi and northern Alabama to its present camp. Serous and mucous diarrhœa have been the prevailing diseases. These fluxes are very often obstinate and protracted; relapses are common, and in young soldiers bring on marasmus. I am credibly informed that on the march through southern Tennessee to Pittsburg Landing the men generally threw away their overcoats, and as they were usually provided with only one blanket and rubber-cloth, they were often severely pinched by cold at night both before the battle of Shiloh and afterward, until about the tenth of June. These cold nights following the heat and fatigues of marching, trench work, and skirmishing by day, were extremely detrimental to the health of the army, producing obstinate bronchitis, mucous diarrhœa, and remittent fevers.

Extract from the Report of Surgeon JOHN N. BEACH, 40th Ohio Volunteers. *Camp near Prestonburg, Kentucky, quarter ending June* 30, 1862.

The 40th Ohio was organized at Camp Chase, Ohio, and remained there about two months. We left camp December 17, 1861, and went by rail to Paris, Kentucky. We left Paris on the 26th of December and marched to Paintville, the march occupying thirteen days. During the march it rained almost incessantly, so that the troops hardly had their clothing dry during the whole time. Immediately after our arrival at Paintville we made a forced march to Prestonburg and took part in the battle of Middle creek. For three days the troops were without tents, proper food, or medical supplies. As a result of this continued exposure half the regiment was on the sick-list, and many died during the next few weeks from typhoid fever and pneumonia. When I joined the regiment at Piketon, Kentucky, April 19th, there were about fifty cases in hospital, several in the last stage of typhoid fever, and quite a number just brought in with it. The deaths occurring during the next few weeks were from typhoid fever. In March an unusual rise of Big Sandy river overflowed the camp, sweeping away the camp equipage, stores, &c. The flood buried a large quantity of grain (corn and oats) very near the camp, which, I have no doubt, had much to do with the malignancy of the fevers in April. Since the first of June our diseases have been much milder in character. The fevers are of a remittent type, and are readily controlled by quinine. The diarrhœas so general in April and May have disappeared to a great extent, but there has been a considerable increase in the number of dysenteric cases. Fortunately the dysentery up to this time has been mild and easily managed by cathartic doses of castor oil and turpentine, or of the salines, followed by opium and entire rest.

Extract from the Report of Surgeon FRANCIS B. ETHERIDGE, 5th Minnesota Volunteers. *Camp on the Tennessee river, June* 30, 1862.

During the first half of the quarter the 5th Minnesota was stationed at Fort Snelling, Minnesota, where catarrhal affections and measles were the principal diseases. The cases of measles frequently terminated in bronchitis or pneumonia. Nothing worthy of note occurred from the time we left Fort Snelling, May 13th, till we reached the Tennessee river, when diarrhœa became prevalent, and occasional cases of cholera morbus occurred. From the time of our landing at Hamburg to the close of the quarter these diseases became more and more prevalent, particularly diarrhœa, which frequently ran into dysentery. We have had as yet no fatal cases, but several continue to resist treatment. The cases of fever which have occurred have mostly been of the remittent type. The extreme prevalence of diseases of the digestive system is, in my opinion, principally owing to the climate, but also to our mode of life in camp, and perhaps in some measure to the water we use. We are encamped on an elevated piece of woodland, where we have some shade, good drainage, and a good supply of water by digging twenty to forty feet.

Extract from the Report of Surgeon JOHN Y. FINLEY, 2d Kentucky Cavalry. *Savannah, Tennessee, quarter ending June* 30, 1862.

At the beginning of the quarter the continued fevers, from which the 2d Kentucky cavalry had suffered during the winter, were gradually replaced by the remittents common in this region during the warmer months. Diarrhœa also became common. More than half the cases treated were acute diarrhœa, largely due, as I thought, to the extremely wet weather and exposure to the night air without tents. The disease was, however, mild in form and very amenable to treatment. May 1st, we were ordered to our present location. The neighborhood is low, damp, and adjacent to large swamps. The drinking water is impure. Since encamping here our sick-list has been large, remittent fevers and diarrhœas being the prevailing diseases. We have also had an epidemic of mumps.

Extract from the Report of Surgeon AIKEN C. MILLER, 14th Kentucky Volunteers. *Cumberland Gap, Tennessee, quarter ending June* 30, 1862.

During the march of the 14th Kentucky from Lexington to Cumberland Gap our men were almost constantly drenched with rain, and often had to lie at night with their clothes thoroughly saturated, and without blankets enough to keep them warm, the weather during our entire march being very cold. This produced many cases of diarrhœa and catarrh. The dews falling in this region of country at night are equivalent to light showers, and the clothes of the troops while without shelter at night were always saturated. The temperature at night is so much reduced that it becomes intolerably cold toward morning. This is a very great source of diarrhœa and dysentery, as well as various pulmonary troubles, such as bronchitis, pleurisy, and pneumonia.

Extract from the Report of the same. Cumberland Gap, Tennessee, quarter ending September 30, 1862.

While stationed at Cumberland Gap the principal diseases of the 14th Kentucky were diarrhœa, dysentery, jaundice, and other diseases of the digestive organs; we have had, besides, quite an epidemic of low, continued fever, but it was of short duration and proved to be very mild. The treatment which gave most satisfaction in cases of watery diarrhœa consisted in the administration of saline cathartics, followed by mild alteratives and astringents, with total abstinence from food and drink for at least twenty-four hours. Dysentery was also amenable to the same course of treatment, but required less purgation and more decidedly alterative measures.

Extract from the Report of Surgeon S. L. Burdett, 4th Kentucky Volunteers. *Camp near Tuscumbia, Alabama, quarter ending June* 30, 1862.

Diarrhœa has been a very common disease in the 4th Kentucky since about the 15th of December last; in fact it was uncommon to see a soldier that did not have the disease, and strange as it may seem, I have known sauer-krant or cabbage to check it in many instances where the most powerful astringents had failed. It is very common to hear soldiers affirm that green corn is good for loose bowels. To a limited extent I have noticed this to be the fact; hence I am led to believe that much of the diarrhœa of our army results from a scorbutic condition of the system.

Extract from the Report of Assistant Surgeon Henry P. Fricker, 20th Ohio Volunteers. *Grand Junction, Tennessee, July* 14, 1862.

Among the diseases from which the 20th Ohio suffer, diarrhœa and dysentery still predominate. Their fatality may be said to be great. Some die in the acute stage of the disease, in others it becomes chronic; the latter cases are much the most frequent, and the patients ultimately die of debility with or without diarrhœa; often a slow but increasing fever sets in, emaciation rapidly follows, and the patient either dies suddenly, or lingers a long time baffling every kind of treatment.

Extract from the Report of Surgeon Henry E. Foote, 22d Ohio Volunteers. *Camp near Corinth, Mississippi, quarter ending September* 30, 1862.

Diarrhœa and dysentery have been the prevailing diseases during the quarter, and were often very obstinate. Much benefit has been derived in these cases from saline cathartics in small doses, and from opiates; some that had resisted other treatment have yielded to Fowler's solution and laudanum.

Extract from the Report of Assistant Surgeon Benjamin F. Keables, 3d Iowa Volunteers. *Bolivar, Tennessee, September* 30, 1862.

The cases of diarrhœa that have been troublesome were all contracted while encamped at Pittsburg Landing on the Tennessee river. I attribute them in part, at least, to drinking the river water. Most of the cases of dysentery occurred while we were encamped near a stagnant pond in the vicinity of Memphis. I think malaria has also acted as a cause of bowel complaints.

Extract from the Report of Assistant Surgeon Charles B. Tompkins, 17th Illinois Volunteers. *Bolivar, Tennessee, quarter ending September* 30, 1862.

The 17th Illinois has been stationed during the quarter at Jackson and Bolivar, Tennessee. We moved from Jackson July 16th. We were encamped at both places on high, rolling ground, with good water convenient to the camp. During July we had several cases of cholera morbus, but the prevailing disease was diarrhœa, which, however, was easily controlled by opiates, together with such stimulants as brandy, ginger, camphor, &c. During September diarrhœas have given place to dysenteries, over which opiates and astringents have very little control. I have, however, found the extracts of belladonna or conium, combined with camphor and quinine, to act admirably. We have had two cases of pneumonia, one of them fatal, and quite a number of cases of ophthalmia, nearly all of a purulent form.

The regiment has been employed on light duty during the quarter, with the exception of a march made from this place to Iuka, Mississippi, *via* Jackson, Tennessee. We went by rail to Corinth, and marched thence to Iuka and back. We were gone seven days, and were under cover only two nights. It rained almost every other day. The exposure seemed to cause dysenteries rather than fevers.

Extract from the Report of Surgeon Carr W. McMillen, 1st East Tennessee Volunteers. *Cumberland Gap, quarter ending September* 30, 1862.

The prevalent diseases in the 1st East Tennessee during the quarter have been diarrhœa and dysentery. Some few of the cases were exceedingly intractable, but the majority readily yielded to treatment; in those characterized by bloody stools the saline treatment proved most advantageous, while opium and rest succeeded best in other cases.

Extract from the Report of Surgeon Jared W. Tuttle, 29th Illinois Volunteers. *Camp near Jackson, Tennessee, quarter ending September* 30, 1862.

During the month of July the most prevalent disease was acute diarrhœa. This I think was attributable as much to the carelessness of the men in regard to diet as to anything in the season or locality; they not unfrequently surfeited upon unripe fruit and green corn half cooked. The disease, however, was readily checked by the use of common astringents, subnitrate of bismuth with opium, or Hope's camphor mixture. The number of cases of malarious origin during the month was forty-seven. There was no difficulty in controlling these with quinia.

During August there was a great diminution in the number of cases of diseases of the digestive organs, and in fact a great improvement in the health of the regiment. This I think was in part owing to a march the troops took about the 1st of the month, which lasted fifteen days. There is nothing that has so marked a tendency to improve the health of troops as moving them.

During September there was a great increase in the number of fevers of malarious origin, but a diminution of all other diseases. The regiment was placed along the railroad line about the first of this month, and the localities requiring guards were of a low, marshy character. The consequence was that nearly all the companies suffered with intermittent fever, which, however, yielded to quinia in all cases.

Extract from the Report of Assistant Surgeon Elliott Pyle, 2d Iowa Volunteers. *Camp near Corinth, Mississippi, September* 30, 1862.

The prevailing diseases during the quarter have been mild malarial fever, dysentery, and diarrhœa. Though some of the cases of dysentery have been of a very severe character, none have terminated fatally or become chronic. The treatment pursued in the earlier stages has consisted in the use of saline cathartics, alternated with opiates and the occasional exhibition of mercury. In the later stages opiates and quinia, with castor oil from time to time, and a nutritious and supporting diet were directed. Acute diarrhœa has been the most prevalent disease in the command. This is undoubtedly the result of those irregularities of life and habit which are peculiar to the soldier.

Extract from the Report of Surgeon Alexander H. Hoff, U. S. Volunteers. *Hospital steamer D. A. January, quarter ending September* 30, 1862.

My observations have been confined to the condition of men placed on board this boat for transportation, most of whom have been subjected to treatment and show evidences of its effects. Most of them are suffering with diseases of the intestinal canal; however, in the last two loads there has been more intermittent and remittent fever complicated with diarrhœa. Whether the diarrhœa is a necessary complication caused by the influences of climate, or depends upon treatment, is a matter of much importance. The condition of the mucous membrane, and the history of cases so far as they can be obtained, points strongly to the treatment, especially to carelessness, exposure, and improper diet permitted, or which cannot be prevented, while taking the more potent remedies which our surgeons are in the habit of prescribing—calomel, mercury with chalk, and sulphate of quinia in some proportions seeming to be generally used in all this class of cases. This treatment, so far as my experience goes, cannot be necessary, as very many of these men, as high as fifty per cent., are salivated, yet the fever still persists; while on the contrary, with a proper diet and close attention to avoid everything that would have a tendency to irritate, good effects are at once seen with the smallest quantity of antiperiodics.

Most of the men sick at the present time are from the southern portions of Indiana, Illinois, Ohio, &c., who, if they were so unfortunate as to miss an attack of ague in the fall, would consider themselves in a dangerous condition. These men are being sent to general hospital as rapidly as possible; but I have no confidence that they will be worth anything to the service until next spring, those that have returned being obliged to be sent away again, the fever having reappeared on the slightest exposure.

I have had no experience in reference to prophylactics, but cannot say that I am in favor of the whiskey ration, even as a vehicle for the administration of the sulphate of cinchona.

Extract from the Report of Surgeon William W. Welch, 53d Illinois Volunteers. *District of West Tennessee, October* 1, 1862.

I observed last spring not only that the epidemic diarrhœa which then prevailed in the 53d Illinois could not be readily arrested by any means ordinary or extraordinary; but that even when much protracted it was unattended by the exhaustion which almost universally follows sporadic cases, the men who were its subjects keeping about their duties as usual, with very little perceptible diminution of strength, merely suffering from the inconvenience. I noticed also that in those cases where, by the use of alteratives and astringents, the disease was overcome, either fever in some form or jaundice was the result—jaundice in particular; and even at the present time, although a few cases are serious, I am constrained to believe that the disease is for the most part salutary.

Extract from the Report of Surgeon Franklin Blades, 76th Illinois Volunteers. *Camp on the Tallahatchie river, Mississippi, quarter ending December* 31, 1862.

At the commencement of the quarter the 76th Illinois was stationed at Columbus, Kentucky; shortly after it moved to Jackson, and thence to Bolivar, Tennessee. At Bolivar we remained nearly two months. During October measles prevailed, and remittent fever was common. There were also very many cases of intermittent fever and of mild diarrhœa, which readily yielded to treatment. During November the epidemic of measles subsided, but the number of cases of other diseases, especially those just named, increased. In the latter part of November we left Bolivar and moved south to our present camp, ten miles south of Oxford, Mississippi. Here we have experienced a sudden and considerable increase of sickness. Acute diarrhœa continues to be frequent, and dysentery, typhoid, typho-malarial, and remittent fevers of a grave character are beginning to prevail.

In the treatment of dysentery I have latterly discarded mercurials altogether. In recent cases I invariably begin the treatment with a full dose of sulphate of magnesia, followed, after free evacuation of the bowels, with large doses of ipecacuanha and opium. I do not often have to repeat the sulphate of magnesia. In nearly every instance the disease has been cut short in from twenty-four to forty-eight hours.

Extract from the Report of Surgeon Elias C. De Perry, 46th Illinois Volunteers. *Camp near the Tallahatchie river, Mississippi, quarter ending December* 31, 1862.

On the 4th of October the 46th Illinois left Bolivar, and participated next day in the affair at Matamora, on the Hatchie river near Pocahontas, Tennessee. We had thirty-one officers and men killed and wounded. We returned to Bolivar October 8th, and remained until November 4th, when we marched to La Grange, Tennessee, where we remained till November 28th, when we moved to Waterford, Mississippi, where we arrived November 30th. Here we remained eleven days, after which we went southward and encamped near Yockna station on the Mississippi Central railroad, December 12th. December 22d we marched to our present camp, arriving on the 23d.

The prevailing diseases have been intermittent and remittent fever, diarrhœa, and dysentery. The fevers were caused by exposure in a malarious country, where the men were compelled to sleep in the open air, often getting wet and sleeping in their damp clothes.

The dysenteries were caused, in addition to the above, by the improper manner in which the rations were cooked, and by the use of improper articles of diet. These cases yielded readily to appropriate treatment, so that the patient was seldom kept from duty longer than from three to six days.

The acute diarrhœas were caused by errors in diet and by sleeping on the ground, but on the removal of the causes yielded readily to treatment. We have a few cases of chronic diarrhœa of long standing, most of them having commenced last spring on the Tennessee river, during the months of March, April, and May. The treatment of these cases has been attended with very unsatisfactory results, and it seems almost impossible to relieve them while they remain in camp.

Extract from the Report of Surgeon Joel Morse, 52d Ohio Volunteers. *Edgefield, opposite Nashville, Tennessee, quarter ending December* 31, 1862.

The 52d Ohio left Camp Dennison, Ohio, August 25, 1862, and arrived at Lexington, Kentucky, August 26th. August 30th, we marched to take part in the engagement then progressing at Richmond, Kentucky, but our troops having been defeated before we arrived, the regiment retreated and reached Louisville September 5th. We left Louisville October 1st, and took part in the battle of Perryville October 8th. Subsequently we marched as far as Crab Orchard, and thence *via* Danville to this place, where we arrived November 7th.

During this time we have had a number of cases of fever, principally of malarious origin, and in most cases conjoined with diarrhœa. These fevers, intermittent at first, were apt, if permitted to run any length of time, to assume a remittent or continued form. The most efficient treatment was the free exhibition of quinine and the use of opium and astringents. Just before we reached Edgefield measles broke out, and a considerable number of cases occurred. The first cases were left in hospital at Bowling Green; subsequent ones, with very few exceptions, have been sent to general hospital at Nashville. Many of these patients died in hospital; others, who rejoined the regiment as convalescents, have since died or been discharged; while a number of the remainder, to judge from appearances, will have to be discharged in the future.

We have suffered much from diarrhœa; only slightly, however, from dysentery. The treatment found most efficacious during the first part of the quarter was a combination of quinine and capsicum, with opium and astringents; lately, however, we have preferred to give a dose of castor oil with a few drops of oil of turpentine every third or fourth day, and tonics and astringents on the intermediate days.

Extract from the Report of Surgeon John J. McElroy, 125th Illinois Volunteers. *Nashville, Tennessee, December* 31, 1862.

We have had quite a large number of cases of diarrhœa during the month, but nothing in comparison with the number treated during November. The treatment most efficient has been chiefly opiate, astringent, occasionally alterative.

The form of dysentery which we have had has been readily controlled by a free use of opium and ipecacuanha.

Extract from the Report of Surgeon George W. Phillips, 75th Illinois Volunteers. *Nashville, Tennessee, quarter ending December* 31, 1862.

The 75th Illinois went into the field October 31st, having been in camp for a month previous. Major General Buell's army was ordered to march light during the campaign in Kentucky, and many of the men left their knapsacks, overcoats, and blankets behind. The marches each day were long for raw troops, water scarce and bad in quality, no tents for shelter. Eight days after leaving Louisville the regiment took part in the battle of Perryville, having forty-seven killed and one hundred and sixty-six wounded. After the battle we marched fifty miles to Crab Orchard, Kentucky, exposed at night to a damp, chilly atmosphere, and subjected to new climatic influences. These causes combined produced diarrhœa and bronchitis, the prevailing disorder being a serous diarrhœa.

In the month of November the same disease prevailed, but the proportion of catarrhal affections was greater. The regiment arrived at Nashville November 8th; after this date jaundice and other forms of hepatic derangement became common. There were also many cases of intermittent fever, most of which were complicated with diarrhœa or bronchitis. In many of them the paroxysms were indistinct and the febrile action was not high. Congestion of the kidneys was common in this class of cases.

Extract from the Report of Surgeon Esaias S. Cooper, 83d Illinois Volunteers. *Camp near Fort Donelson, Tennessee, quarter ending December* 31, 1862.

Dysentery and diarrhœa have been common during the quarter. Both have generally terminated favorably when treated with frequent purging by castor oil, followed during the intervals by the free use of opium and ipecacuanha, with stupes to the abdomen applied hot and sprinkled freely with oil of turpentine. The persulphate of iron, acetate of lead, sulphate of copper, nitrate of silver, tannic acid, prepared chalk, and oil of turpentine by mouth and rectum, in various proportions and quantities, have been successfully used in these diseases. The mortality has been less than one per cent.

Extract from the Report of Surgeon Claibourne J. Walton, 21st Kentucky Volunteers. *Army of the Tennessee, quarter ending December* 31, 1862.

During the quarter there have been twenty-one cases of intermittent and remittent fever, two of typhoid fever, forty-three of diarrhœa, and thirteen of dysentery, in the 21st Kentucky. The prevalence of diarrhœa and dysentery is partly due, no doubt, to the deficiency of vegetables, such as potatoes, onions, &c. The remedies I have employed in the treatment of diarrhœa are such as are usually administered, with the addition of a stimulating emetic at the onset of the attack. I begin by giving, in most cases, a mustard emetic, with or without ipecacuanha, aided by large draughts of warm water. This is my favorite remedy, and I can safely say that it relieves at least half the cases without any other medicine. Its beneficial effect in diarrhœa, as well as in cholera morbus, is most remarkable.

Dysentery occurred chiefly in men of weak and debilitated constitutions. It was successfully treated with opium, ipecacuanha, and capsicum, with the free use of whiskey or brandy. Mercurials were seldom admissible.

Extract from the Report of Surgeon Thomas M. Cook, 101st Ohio Volunteers. *Camp near Murfreesboro', Tennessee, quarter ending December* 31, 1862.

The 101st Ohio left Louisville, Kentucky, October 1st, as a part of the Ninth Division, commanded by General R. B. Mitchell, and reached Nashville about the middle of November. When they set out the number of diarrhœa cases was already considerable, and as they had no tents and were much exposed the cases began to assume a grave type, and were complicated by fevers of malarial origin. The latter soon assumed a low typhoid type, and although we had lost but two men up to the 1st of December, yet the daily sick-list was very large. In the treatment of diarrhœa quinine, ipecacuanha, sulphate of magnesia, oil of turpentine, blue pill, opium, and various mineral and vegetable astringents were employed, but the cause being ever at hand the cases either resisted them altogether or continually recurred.

Extract from the Report of Surgeon Martin R. Gage, 25th Wisconsin Volunteers. *Columbus, Kentucky, quarter ending March* 31, 1863.

During the quarter the most common diseases have been diarrhœa and dysentery, remittent or bilious fever, pneumonia, bronchitis, and rheumatism.

Diarrhœa has been the most common affection since the 25th Wisconsin was stationed at Columbus, Kentucky. The fæces are copious, discharged frequently, and are of a liquid or watery character; sometimes the ingesta are thrown off almost as taken into the stomach. Some cases are accompanied with griping pain in the bowels, others are entirely free from it. The tongue is generally furred, but ordinarily there is no fever, except as the consequence of suddenly checking the discharges by improper remedies. Doubtless the principal causes of the complaint are the change from the extreme dry and cold atmosphere of Wisconsin and Minnesota to the more moist and relaxing influences of this region, together with the use of the impure Mississippi and surface waters for drinking purposes.

In the treatment, ordinarily a dose of castor oil is at first prescribed, followed by an opiate, and, if thought advisable, an astringent such as acetate of lead or tannic acid. If this does not prove effectual, the bowels may again be cleared by a mild purgative, followed by an opiate combined with alterative doses of calomel and some form of astringent. The cases treated in quarters were generally found much more obstinate than those in hospital, owing, no doubt, to the circumstance that the diet of the latter can be regulated and controlled better.

Dysentery has prevailed to some extent—frequent and scanty evacuations of mucus and blood being accompanied by more or less tenesmus and griping pains low in the abdomen. Fever is a common symptom, and is often of a very high grade, sometimes assuming a bilious remittent character. The treatment I have chiefly used is as follows: The bowels are moved by castor oil or rhubarb, then as much opium is given every four hours as the system will bear, combined with calomel and ipecacuanha, and this treatment is continued, with the occasional use of mild laxatives. In those cases in which the accompanying fever is clearly of a paroxysmal character, quinine is used in as large doses as the stomach will bear, for the purpose of interrupting the progress of the fever. This effected, the dysenteric symptoms usually very soon subside. In those cases in which there is much tenderness of the abdomen and much tympanites, warm fomentations and counter-irritation by mustard are useful, and at a later period blisters are beneficial. In many cases it is found desirable to resort to the use of injections. I usually make use of acetate of lead or tannic acid combined with laudanum, sometimes of laudanum alone, in a little starch-water. The enemata thus used are small in quantity and frequently repeated.

Extract from the Report of Surgeon JAMES S. WHITMIRE, 6th Illinois Cavalry. *Steamer Lasalle, Yazoo Pass, Mississippi, quarter ending March* 31, 1863.

During the month of January the 6th Illinois cavalry was stationed twenty miles east of Memphis, Tennessee, guarding the railroad. February 13th we moved to the neighborhood of Memphis, and March 3d shipped for our present station. Throughout January and February the prevailing diseases were diarrhœa and dysentery, with intermittent and continued fevers of a low grade. Since embarking we have sent back to general hospital thirty-six men, mostly on account of derangements of the alimentary canal, accompanied by a low grade of fever, which frequently manifests a periodical character, chills or diarrhœa occurring at regular periods. This character of diarrhœa, if left to itself, is almost sure to terminate in typhoid fever.

In my treatment of all these bowel diseases I make use of a small quantity of sulphate of cinchona, sulphate of quinia, or an extract of the *cornus Florida*, (which I have prepared myself at every opportunity,) and they yield very readily to this treatment in connection with opiates, turpentine, &c.

Extract from a Report of Medical Inspector EDWARD P. VOLLUM, U S. A., *April* 23, 1863.

* * * The surgeons in charge of the hospital transports and floating hospitals inveigh against the character of patients sent to them from the regimental hospitals, many of them dying soon after reception, and sometimes while being conveyed from the ambulances to the boat. They also complain of the number of cases of salivation sent them from the same source. I saw two cases of mortification of the cheek from mercurialization. In both, one side of the head was greatly swollen, and a circular black surface about three inches in diameter occupied the central part of the cheek. Copious discharges of the foul secretions from the mouth rendered approach to the patients sickening.

A number of cases of sudden death have occurred on these boats and in the army of the Tennessee, concerning which I suppose you have received reports. *Post mortem* examination reveals no other lesions than a congestion, passive, doubtless, of the membranes at the base of the brain, and particularly of the medulla oblongata, with copious serous effusion. These sudden deaths have occurred altogether in cases of chronic diarrhœa, and the surgeons think they have noticed a relationship between congestion of the conjunctiva, which has assailed all the cases noted, and the tendency to sudden death, or rather the serous effusion causing it. A case of this kind happened on the steamer on which I took passage up the Mississippi from Memphis. The patient, a discharged soldier suffering from chronic diarrhœa, sat near a hot stove, where the by-standers left him for their breakfast; returning, they found him on the floor dead, with the appearance of having been convulsed. The body presented the emaciated appearance common in diarrhœa. The day previously he had expressed himself better than usual. In the evening, feeling feverish, he drank freely of water; before going to the stove he said he felt better than usual.

Extract from the Report of Surgeon JOHN E. SANBORN, 27th Iowa Volunteers. *Jackson, Tennessee, April* 30, 1863.

During the last month we have had but few cases of continued fever. A number of cases apparently threatening to become serious were speedily cut short with mercurials followed by quinine. The most alarming case was that of Lieutenant B., of company K, who had a violent chill followed by fever of extraordinary severity and duration. This was broken up by the use of quinine, but within forty-eight hours severe pneumonia (congestion?) of the right lung was developed, which in a few hours threatened to be speedily fatal. He was rescued from this imminent danger by the prompt use of blisters, with brandy, carbonate of ammonia, and quinine, and is now convalescent. Nearly all our cases of protracted fever assume a remittent or intermittent form, and seem to demand antiperiodics.

Diarrhœa is less frequent than heretofore, partly from increased care in cooking, all cooking being done in messes and under careful supervision, and partly from the effects of an order prohibiting the sale of pies, cakes, &c., in the camp. Most of the diarrhœas assume primarily the form of hepatic congestion, and are generally speedily relieved at the outset, if opportunely treated with somewhat brisk mercurials, followed with saline laxatives. Most of the catarrhs have been the result of exposure to cold and wet, or have followed measles.

Extract from the Report of Surgeon CHARLES A. HUNT, 126th Illinois Volunteers. *Jackson, Tennessee, April* 30, 1863.

Nearly half the cases of sickness observed in the 126th Illinois during April have been bronchitis and pneumonia, while nearly all the remainder have been dysentery, or malarial fevers complicated with dysentery. The dysenteric cases were quite tractable. Aperient remedies, such as blue pill, sulphate of magnesia, and castor oil, combined with opiates to allay the pain, have been very successful.

Extract from the Report of Surgeon ROBERT J. FARQUHARSON, 4th East Tennessee Volunteers, *to* Medical Inspector FRANK H. HAMILTON, U. S. A. *Near Nashville, Tennessee, June*, 1863.

[Dr. Farquharson reports that some two or three months previously the 4th East Tennessee was vaccinated, ugly ulcers and a troublesome eruption resulting in many cases.] Upon a general examination of the men the following conditions were observed: There was a general complaint of malaise or rather of debility, which prevailed to such an extent and in so marked a degree as to present to a casual observer the appearance of confirmed laziness, the men sitting down even when you were talking to them, and exhibiting, when apparently well, the greatest lassitude and indisposition to duty or exercise of any kind. The

general appearance of the men in the face is not anæmic; they have rather a good, dark, ruddy complexion. Headache is quite common, as are also dyspeptic symptoms, loss of appetite, nostalgia, vomiting, and eructation of food. The pulse, as far as observed, is generally smaller and more rapid than in healthy men. The tongue in almost all cases presents the same appearance—broad, flabby, smooth, and without the slightest appearance of fur, no matter what may be the immediate disease for which the patient presents himself. In a few cases, when the stomach was implicated, the tip of the tongue was red and the papillæ apparent. The gums were found to be preternaturally red, in most instances retracted from the teeth, and inclined to ooze blood upon pressure. Though in many instances pain in the bones was complained of, in none have nodes, or the flatness and hardness of the muscles of the calf of the leg, so often described as a peculiarity of nautical scurvy, been observed. Finally, attention should be called to the most prevalent and the most important consequence of the cachexia present—dysentery. Three causes may be assigned for the dysenteric cases, and probably all had an agency in the production of this disease, viz: Exposure to rain with imperfect protection and sleeping on the wet ground, the use of hard limestone water from a well near by, and, lastly, the scorbutic taint.

This dysentery is of an acute character, with bloody stools from the beginning, and none of the cases present typhoid symptoms; it seems to be more of the nature of bloody diarrhœa; is easily checked by a laxative followed by an opiate, but soon returns, as might be expected, the causes remaining in full force.

The weather since our arrival in Nashville has been cool, with frequent showers. The site of the encampment is flat, too much shaded, imperfectly drained, and has been used by other troops. The latrines being imperfectly filled with earth add much to the offensiveness of the air and somewhat to its insalubrity. The water used is from a well of very hard limestone, kept low by constant use; such water has always been known to produce irritation of the bowels in persons coming from districts supplied with purer water.

Extract from a Report of the Inspection of Camp and Field Hospitals of General Grant's Army in the field in the rear of Vicksburg, Mississippi, for the month of June, 1863, *by* Medical Inspector John E. Summers, U. S. A.

Water for drinking purposes is supplied by springs and recently dug wells, the cistern water having been exhausted; indeed it only lasted a few days. It is hard water, containing lime and magnesia with a large quantity of vegetable matter in solution. It certainly has the effect of inducing diarrhœa. I think I may safely say that one-half or more of the command on duty have been suffering from a very relaxed condition of the bowels. I learn from old residents of this vicinity that the only use made for the last thirty years of the water from this source has been for cooking and washing, cistern water having been substituted even in the large fields for the negroes. * * * * .

I regret to say I found some brigades that had been in camp ten days or more and were without sinks or any convenience for the command or even the officers, and a general indifference exhibited by them to this subject. I have endeavored to impress the importance of the subject on the minds of brigade commanders, and have since learned that a better condition of things now exists. Where sinks had been made, they were seldom found attractive for the men; without arbors over them as a general thing, and not unfrequently without a pole to sit on. It was claimed that dirt was thrown into them every evening. Their position was never so far off as it ought to have been, but this was a military necessity. It was also claimed that as rapidly as they were filled they were covered over and others dug. I am impressed with the fact that too much, and indeed an inexcusable, indifference was manifested all the way along the line through the camps, with some very few exceptions, to the importance of proper attention to this subject. I will add that the men have been in the habit of going out into the bushes, and not unfrequently only thirty or forty feet from some of their tents, and relieving themselves; in fact human excrement has been promiscuously deposited in every direction, until the atmosphere, as the dampness of evening and night approaches, is so heavily loaded with the effluvia that it is sickening. * * * *

Extract from the Report of Surgeon Edwin C. Bidwell, 31st Massachusetts Volunteers. *Port Hudson, Louisiana, quarter ending June* 30, 1863.

The 31st Massachusetts left Baton Rouge April 1, 1863, for Algiers by steamer. April 9th it went by railroad from Algiers to Berwick Bay, thence marched on the 11th up the Teche. It was engaged in the battle of Fort Beasland April 13th. Continuing its march to Opelousas, Alexandria, and Semmesport, (stopping a few days at each of the places named,) we arrived in the immediate vicinity of Port Hudson May 23d, and were engaged in the siege of that place until the present time, participating especially in the battles of May 25th and 27th and June 14th. Its camps since our arrival here have been in rather dense groves of magnolia, beech, and other large forest trees. The men have been chiefly engaged in skirmishes in rifle pits or other situations exposed to the direct rays of the sun as well as to the fire of the enemy, or on fatigue duty in trenches similarly exposed. The entire loss by battle during the quarter was fifty-eight.

During the quarter I have recorded seven hundred and fifty-three cases of intermittent fever, being an average of nearly nine per day. All these I have considered as having been contracted at Fort Jackson last fall, and look upon them as vernal relapses. They have for the most part been easily managed. Most of them have yielded to a single dose of ten grains of quinine; very few have required more than a second dose. Within the last few days another form of fever has appeared, due, I presume, to exposure to the direct rays of the sun. It is of a mild grade, the most notable and constant symptom being a debility quite disproportionate to other evidences of disease.

We have also had a good deal of diarrhœa, which I have attributed in large measure to drinking water too freely while on the march. The water used was chiefly turbid, and obtained from the bayous communicating with the Red or Mississippi

rivers, which often had a disagreeable taste and odor. With the exception of sulphate of magnesia, which I find indispensable in the treatment of diarrhœa, no single remedy has proved so useful during the last quarter as the infusion of the bark of the sweet-gum tree, (*Liquidambar styraciflua,*) which is abundant everywhere in this region. Many cases assuming somewhat of the dysenteric character are uncontrollable until the patient loses his appetite; under absolute diet they recover readily.

It should also be noted that diarrhœa has been a prominent symptom in most, if not all, the cases reported as continued fever; indeed there is no well-defined boundary between the cases referred to those two titles. One probable cause of the prevailing diarrhœa is the use of unfiltered water of the Mississippi river. By my direction some companies have made arrangements for precipitating the impurities of the river water by the use of alum to render it more suitable for drinking purposes; others are about procuring filters at the expense of their company funds. The results of these expedients remain to be ascertained. Another fruitful source of bowel affections I suppose to be the sale of crude fruits, pastry, and various vile beverages in and around the camp.

Extract from the Inspection Report of the Department of the Cumberland for the month of August, 1863, *by* Medical Inspector Frank H. Hamilton, U. S. A.

I have noticed everywhere in the department that the free use of berries, peaches, and green corn, with other fruits and vegetables, although the fruits were seldom ripe when eaten, has had a salutary effect upon muco-enteric affections. If they have occasionally increased or produced a diarrhœa, they have also cured or prevented many more.

Extract from the Report of Surgeon John C. Welch, 20th Kentucky Volunteers, *in charge of Prison Hospital No. 2, Louisville, Kentucky, for September*, 1863.

Subnitrate of bismuth in large doses seemed to exert as much influence in controlling obstinate cases of chronic diarrhœa as any other single agent in the materia medica. Opium in grain doses, combined with quarter-grain doses of sulphate of copper, is also an admirable remedy, repeated at intervals ranging from two hours to six, according to circumstances. The persulphate of iron combined with an equal quantity of opium constitutes a valuable remedy in acute dysentery.

Extract from the Report of the same for October, 1863.

The subcarbonate of bismuth acts admirably well as a curative agent in chronic diarrhœa. The only two cases we had of that disease yielded promptly to its influence in the short space of forty-eight hours. It acts like a charm. It should be essayed in all obstinate cases, as it has displayed such beneficial results in the few cases in which I have had an opportunity of testing its superior powers.

Extract from the Report of the same for November, 1863.

The subcarbonate of bismuth has displayed its curative powers in the cases of chronic diarrhœa treated during the month. It has been exhibited in doses of fifteen grains repeated at intervals of four hours. The patients have uniformly improved under that treatment in thirty-six hours. It is worthy of a more extended trial, and I would recommend its use in all inveterate cases of chronic diarrhœa.

Extract from the Report of Surgeon James Bryan, U. S. Volunteers. *Opposite Vicksburg, June* 27, 1863.

We found that our diarrhœas and dysenteries, when checked suddenly, were often transformed into remittent and intermittent fevers, and that the morbid impression in the lower bowels was transferred to the stomach. The cases were usually quite severe, though mild ones were occasionally observed. Indeed the prevalent disease of the hospital, in addition to any other the patient might have, was diarrhœa. This was attributable to two causes: First, to the drinking water used; and secondly, to the climate. Something might be added also in reference to the rations, which in the first part of the month were deficient, but were subsequently supplied by authorized foraging parties. *. * * . During the month the best preventive we found for diarrhœa and dysentery, as well as for a peculiar gastralgia which was common, was the free use of citric acid as a lemonade. By diminishing the coffee ration, getting fresh milk and administering it boiled, and using freely of the citric acid, we cut down these diseases very rapidly. The premonitory symptoms were generally relieved by a free resort to this treatment.

Extract from the Report of Surgeon Victor H. Coffman, 34th Iowa Volunteers, *to* Medical Inspector George W. Stipp, U. S. A. *Department of the Gulf, February* 8, 1864.

The 34th Iowa left St. Louis December 1, 1862, on transports, and arrived at Helena, Arkansas, December 7th. Here it went into camp, suffering at the time from epidemic mumps and measles. December 22d we again embarked to take part in General Sherman's expedition against Vicksburg, leaving in camp one hundred and twenty men unable to go with the regiment. Subsequently we took part in the expedition against Arkansas Post, and returned to St. Louis about the middle of January. June 6th we set out from St. Louis to join the investing force in front of Vicksburg, and took position on the extreme left, resting upon the river. Our camp was situated between the river and the large bayou, and was almost a complete cypress swamp. Here the command suffered severely from malaria, and performed the hardest service, skirmishing, digging rifle pits at night, and doing picket duty. The entire command was on duty every night, which soon disabled the soldiers, leaving them an easy prey to the diseases of the summer. Thus prostrated, they readily succumbed to attacks of dysentery, which became alarmingly

fatal. The only treatment that proved at all successful was, at the outset, to administer from twelve to twenty grains of calomel with an ounce of castor oil, followed by sedative doses of quinine, stimulants, and a nutritious diet. After the first stage, aromatic sulphuric acid was our sheet-anchor.

Extract from the Report of Surgeon JOHN W. ANGELL, 23d Wisconsin Volunteers, *to* Medical Inspector GEORGE W. STIPP, U. S. A. *Department of the Gulf, February* 11, 1864.

The 23d Wisconsin landed at Young's Point, Louisiana, about eight miles above Vicksburg, January 24, 1863. Here we went into camp on a low marshy bottom, surrounded by cypress swamps, and the ground nearly covered by water. We remained in this encampment until February 14th, and during this time suffered much from miasmatic disease. At one time there was scarcely a well man to be found in the regiment. * * * Diarrhœa and typho-malarial fevers were the principal diseases prevailing, and a large percentage of the cases proved fatal. The diseases contracted at this point are still affecting the regiment, and more than one-fourth of those now daily excused from duty first became diseased at that place; yet the cause of all this was not solely the unhealthy locality of the camp ground, but also the unusual exposure of the men to the inclemency of the weather, their previous long sojourn on crowded transports, their scanty rations, the unhealthy character of their drinking water, all operating upon systems not yet inured to the hardships of a soldier's life.

Extract from the Report of Surgeon OTIS E. FRENCH, 114th Ohio Volunteers, *to* Medical Inspector GEORGE W. STIPP, U. S. A. *Department of the Gulf, February* 20, 1864.

The 114th Ohio was mustered in during September, 1862, and went into camp September 20th, near the fair ground at Marietta, Ohio, on the east bank of the Muskingum river. Here dampness and malaria caused much sickness, chiefly diphtheria and intermittent fever. November 29th we embarked on the steamer Izetta for Cincinnati, where we arrived on the 30th, and went on board the steamers Duke of Argyle and Prima Donna for Memphis, Tennessee, where we went into camp December 6th. During our stay measles broke out, and when we embarked, December 20th, we left twenty cases of measles in general hospital. January 2, 1863, we started on the campaign against Arkansas Post, and subsequently proceeded to Young's Point, where we arrived January 23d, and took part in the operations against Vicksburg. August 15th we arrived at Carrollton, Louisiana.

During all this time diarrhœa has been our principal disease. It began to trouble us after a few weeks of camp life. As we proceeded south and the troops were exposed to malaria, it became more grave and frequently ran into hepatic flux. I have hardly observed a true case of acute dysentery such as is so frequently seen in the north. Malaria, indeed, has been the great cause of sickness in the western army, and the exciting cause of many diseases not generally attributed to this agent. The scorbutic agency also, in my opinion, has been another great cause of fatal sickness; it is usually complicated with other diseases, and hence is not always recognized. I have seen many obstinate cases of chronic diarrhœa which immediately improved as soon as the patient was put upon fresh beef or raw onions with proper anti-scorbutic remedies.

Extract from the Report of Surgeon MADISON REECE, 118th Illinois Volunteers, *to* Medical Inspector GEORGE W. STIPP, U. S. A. *Department of the Gulf, February* 21, 1864.

The 118th Illinois went on board the steamboat Planet at St. Louis with orders for Memphis, Tennessee, December 2, 1862; from this time until the last of January, 1863, it was confined on transports the greater portion of the time. The water in the river being low, the boats frequently grounded on the numerous sand-bars, and the men had to expose themselves in getting them off. The greater portion of the time flour was issued instead of bread, and no proper means of baking it existed. Altogether, they were in a pitiable condition, confined, when below decks, in an impure atmosphere, or lying on the upper decks exposed to wind and rain. As a consequence they sickened in great numbers. One hundred sick were sent to hospital when we left Memphis December 20th. December 26th we went up the Yazoo river. Here very many of the men suffered with acute diarrhœa, which was attributed to the use of the water of the river. The river was low, and was the receptacle of all kinds of filth, from the great number of troops on board the transports assembled in it; moreover, the Mississippi river was rising and arrested the current of the Yazoo, which made it much worse. After the success at Arkansas Post the scene changed, and the health of the men began to improve immediately after going into camp on shore.

Extract from the Report of Surgeon CHARLES V. MOTTRAM, 6th Michigan Volunteers, *to* Medical Inspector GEORGE W. STIPP, U. S. A. *Department of the Gulf, March* 1, 1864.

About the middle of May, 1863, the 6th Michigan arrived before Port Hudson and took part in the siege. After the surrender of the place it remained as part of the garrison until the present date. During all this time chronic diarrhœa has been the most serious of our diseases. It is the result of constant exposure to miasmata and a diet consisting almost exclusively of salt meat and hard bread. Vegetables have been very seldom issued; not on an average over once in two weeks, and fresh beef not more frequently.

Extract from the Report of Surgeon WILLIAM BERRY, 7th Kentucky Volunteers, *to* Medical Inspector GEORGE W. STIPP, U. S. A. *Department of the Gulf, April* 27, 1864.

The 7th Kentucky was mustered into service September 22, 1861, and was then known as the 3d Kentucky. Although diarrhœa and dysentery prevailed from the time the regiment was organized, no deaths from these diseases occurred until May, 1862. We had an epidemic of measles in September and October, 1861, and this was followed by many cases of pneumonia and

typhoid fever. November 17, 1862, we embarked at Point Pleasant, Virginia, for Cincinnati, and thence went, still on transports, to Memphis, Tennessee, where we arrived December 1st. After the men had been confined on the transports for some fifteen days, diarrhœa and dysentery prevailed to such an extent that we were compelled to leave about fifty men in general hospital at Memphis. After re-embarking on transports at Memphis for the Yazoo river, diarrhœa continued to increase, and prevailed in the regiment until the 1st of April. It was of a more fatal character than any I had previously seen.

While at Big Black river bridge in May, cases of remittent, typho-malarial, and intermittent fevers became numerous, and continued to increase in frequency during the siege of Vicksburg and until the last of August. Diarrhœa and dysentery also continued to be prevalent, and a number of the chronic cases died. The same condition continued during our subsequent movement to Port Hudson and to Carrollton, Louisiana. During most of the time fresh beef was not issued more than once in fifteen days, and fresh vegetables not oftener than once in twenty. During marches, however, the men were often able to obtain fresh vegetables for themselves, and to this circumstance I attribute the mild character and small number of cases of scurvy. In but few of them were the limbs swollen and spotted as is seen on ship-board. I look, however, upon the fatal form of diarrhœa we experienced as a scorbutic disease, and believe that it is sooner relieved by fresh vegetables than by fermented acids. So far as I have heard from them, nearly all of our men who were discharged for chronic diarrhœa and lived to get home have recovered.

Extract from the Report of Medical Inspector Norton S. Townshend, U. S. A. *Louisville, Kentucky, November* 26, 1864.

There appears to be an opinion prevalent that colored troops suffer more than white troops when strictly confined to the established army ration. My own observations lead me to the same opinion, at least so far as the use of hard bread from thoroughly bolted flour is concerned. Where this is a principal article of diet with those who have not been accustomed to it heretofore it occasions constipation, and is followed by various derangements of the digestive system and often by diarrhœa and dysentery.

Extract from the Report of Surgeon Michael D. Benedict, 75th New York Volunteers. *Santa Rosa Island, Florida, quarter ending March* 31, 1862.

Since the 1st of March we have had a large number of cases of remittent fever, mostly of a mild type, although a few have shown a strong tendency to congestion. It seems like a fever of acclimation, and has been most successfully treated with quinine. Dysentery and diarrhœa have been very common complaints, and have almost invariably been produced by eating excessively or by improper food. Only a few cases of these disorders have proved obstinate and unmanageable.

Extract from the Report of Assistant Surgeon George Clary, 13th Connecticut Volunteers. *New Orleans, Louisiana, quarter ending June* 30, 1862.

The 13th Connecticut volunteers arrived at Ship Island April 12th, after a voyage of twenty-three days from New York. The regiment had been quartered during the winter in a large carriage factory at New Haven. Measles and bronchitis had prevailed extensively, and very many of the men were still suffering with severe coughs and were much debilitated. We had seven deaths on ship-board, five from typhoid fever and two from measles. Immediately after going into camp on Ship Island the general condition of the regiment began to improve; but dysentery soon made its appearance. The evacuations in most cases were bloody, but the disease usually yielded readily to rest and appropriate treatment; it was not generally accompanied with fever or signs of severe inflammation.

Extract from the Report of Surgeon James M. Bates, 13th Maine Volunteers. *Ship Island, Mississippi, for the six months ending June* 30, 1862.

The organization of the 13th Maine was completed December 31, 1861, at Augusta, Maine, where it was encamped on the United States arsenal grounds while organizing, and afterward until February 18, 1862. About the first of December measles broke out in camp, and during that month and the following we had about one hundred and twenty-five cases. The disease was introduced by one of a squad of recruits who arrived in camp at night, and who was found well broken out next morning. In a majority of instances the disease assumed a severe type, and was complicated with congestive inflammation of the lungs and a typhoid state of the system, requiring tonics and stimulants to be used freely. In the uncomplicated cases, where the fever was of the sthenic form, the usual diaphoretic and expectorant plan of treatment was adopted.

During our stay at Augusta the troops were quartered in tents provided with stoves and plenty of dry hard wood, and in my opinion suffered more from over-heated tents and consequent sudden transitions from heat to cold than from cold itself.

On the 18th of February, 1862, the regiment left Augusta by railroad, proceeded to Boston, where it was quartered in Faneuil Hall for three or four days, when six companies embarked on the steamer Mississippi, in company with the 30th Massachusetts regiment, for Ship Island, where they arrived on the 20th of March, with the loss of but one man, after a voyage of delays and accidents. The remaining four companies at the same time proceeded to New York, and embarked on the steamer Fulton for Ship Island, in company with the 12th Connecticut regiment, arriving on the 8th of March, after a short passage and without the loss of a man.

During the remainder of the spring and early part of summer the regiment was in tents pitched upon the damp sand, and without floors. Soon after our arrival at Ship Island diarrhœa became very prevalent, but in most cases yielded quite readily

to alterative treatment followed by astringents, and in some cases by tonics, such as quinine, &c. We had but little dysentery or rheumatism during this time considering the amount of exposure to which the men were subjected.

During the months of May and June we had twenty-five or thirty cases of diphtheria of a very malignant form, which, in a majority of cases, proved fatal in spite of tonic and stimulant treatment with quinine, tincture of the chloride of iron, chlorate of potassa, brandy, whiskey, &c.

Our camping ground on Ship Island was low and sandy, with water within three feet or less of the surface, rendering the tents very damp during the spring months, especially at night.

Extract from the Report of the same, Ship Island, Mississippi, quarter ending September 30, 1862.

During the past quarter six companies have been stationed at Forts Jackson and St. Philip, two companies at Forts Pike and Macomb, and the remaining two at Ship Island, which has been the headquarters of the regiment. During the last half of the quarter the six companies at the two first named forts have all been stationed at Fort St. Philip, and the two companies at Forts Pike and Macomb both at the latter. The chief diseases in that portion of the regiment which has been at Ship Island were diarrhœa of a bilious character, and dysentery. Alterative treatment, followed by astringents and tonics, has been almost universally adopted. Astringents, uncombined with or preceding alteratives, we found almost sure to aggravate the symptoms and protract the recovery. Dysentery has been inclined to assume a typhoid form, and very early required tonics and nourishment freely administered.

The diet of the sick has been very good, as we have been able during the summer to procure from the coast fruits, eggs, chickens, and through the months of August and September a limited supply of vegetables, the good effects of which, both in hospital and in quarters, have been very marked. No indications of malarious influences were observed on Ship Island, and but one or two cases of scurvy occurred, and these began to improve rapidly under the free use of potatoes, onions, and lemon juice.

The prevailing diseases at Forts Jackson and St. Philip have been diarrhœa, intermittent fever, and a few cases of scurvy. The food at these forts has been of good quality, with, however, but a limited supply of vegetables a portion of the time. A large majority of the cases of sickness, especially of intermittent fever, occurred at Fort Jackson. There has not been an unusual amount of sickness either at Forts Pike or Macomb, and no intermittent fever, but a good deal of diarrhœa. River water is used almost wholly by the troops, and at first seemed to be the cause of some of the diarrhœa which prevailed, but no such effect is now noticed. The intermittent fever has generally been of a mild form, yielding in most cases in two days to fifteen grains of quinine given in three equal doses during the apyrexia. After two days two grains twice a day have been given until the appetite and strength returned. To those who were found to be very susceptible to malaria daily doses have been administered, and it has seemed to exercise a prophylactic influence, as those to whom it was regularly administered were less affected than others during its use.

It has been observed that those of our men who had been previously reduced by chronic diarrhœa and other debilitating causes were much more liable to attacks of the chills than those who were stronger. These have been treated with daily doses of whiskey and quinine, together with tincture of the chloride of iron, with seeming good results.

Extract from a Report by the same, to Medical Inspector George W. Stipp, U. S. A. *Department of the Gulf, February* 7, 1864.

The 13th Maine arrived at Ship Island, Mississippi, during March, 1862, and remained there until July, when parts of it were ordered to garrison the forts at the entrance of Lake Pontchartrain and the forts at the mouth of the Mississippi river. In August, 1863, we were transferred to New Orleans. We had no miasmatic fevers on Ship Island, but they prevailed among the companies stationed at the forts, especially at Forts Jackson and St. Philip, where in some months we had nearly five hundred attacks in a command numbering six or seven hundred; quotidian or tertian intermittents were the most frequent types, but there was also a good deal of remittent and a few cases of typho-malarial. Since leaving these forts those who suffered most still continue to have occasional attacks, chiefly mild tertian intermittents. It should be mentioned also that many of our cases of chronic diarrhœa have occurred among those who had for months suffered repeated attacks of intermittent fever, which seemed to have produced a general functional derangement of all the abdominal viscera.

Extract from the Report of Brigade Surgeon Rufus King Browne *on the health of the troops at Ship Island, Mississippi, quarter ending March* 31, 1862.

Numerous cases of diarrhœa and dysentery, complicated with biliary derangement and continued fever, occurred among the troops. These were to be attributed to the brackish character of the drinking water and the want of a due proportion of fresh vegetables in the diet. Many of the cases of diarrhœa became chronic and incurable.

Extract from the Report of Brigade Surgeon Thomas Hewson Bache. *Ship Island, Mississippi, for the month of April*, 1862.

The principal diseases of the troops on Ship Island have been diarrhœa and dysentery, not owing so much to the climate as to the quantity and quality of the food eaten. The increased ration is one probable cause. There is a bakery here, and the bread is issued while too fresh. There are also many sutlers and peddlers of eatables. Latterly there has been considerable increase in such traffic.

Extract from the Report of Surgeon Ezra Read, 21st Indiana Volunteers. *Carrollton, Louisiana, quarter ending September* 30, 1862.

May 1, 1862, the 21st Indiana landed at Algiers, opposite New Orleans, where it remained a month, and from thence was transported to Baton Rouge, Louisiana. During the summer the regiment was constantly on duty in the field. During the month of September the regiment made three expeditions and engaged the enemy twice.

The prevailing diseases have been periodic fevers and disorders of the intestinal canal. In the treatment of fevers of the periodic type I have prescribed the sulphate of quinia freely, dissolved in whiskey or brandy, giving, during the stage of apyrexia, from half a drachm to a drachm in five-grain doses at intervals of two hours. In the treatment of diseases of the alimentary canal I have prescribed drachm doses of sulphate of magnesia every three or four hours, and sustained the system and removed local congestion with quinine when demanded. In the treatment of all diseases, in climates and localities as fraught with malaria as this, quinine must stand preëminent, and rest in the recumbent position with rigid diet are imperatively demanded.

Extract from the Report of Surgeon James G. Bradt, 26th Massachusetts Volunteers. *New Orleans, Louisiana, quarter ending March* 31, 1863.

Malarious fevers have been prevalent during the quarter, and wet days have been followed by an increased number of cases of intermittent fever. The cases, however, have chiefly affected men who had suffered with ague before coming to this city. Next in frequency are the diseases of the digestive system. Acute diarrhœa has been prevalent, produced by exposure to sudden changes of the weather, and also by the great difference in temperature between the nights and the days. Another cause, in my opinion, is the diet of the men. No fresh meat has been issued since the 10th of December, 1862, and the full ration of salt meat is unhealthy in this warm climate. Vegetables have been issued very sparingly, except beans, which are allowed once a week, and are a most fruitful source of intestinal irritation. The number of cases of diarrhœa invariably increases after the use of this article of food. They are prepared for food by boiling, baking, or used in making bean soup. In either way I consider them injurious.

Acute diarrhœa has either been treated with antacids and astringents, such as chalk mixture, tincture of kino, &c., combined with opiates, or by first evacuating the intestinal canal with castor oil and oil of turpentine, followed by opium pills. This treatment, when aided by rest and low diet, generally effects a cure in a few days. There have been also a few cases of chronic diarrhœa. These have almost always succeeded the low grades of malarious fever, and have proved very obstinate. The remedies upon which most reliance has been placed are tonics, aromatic sulphuric acid, which sometimes succeeds admirably, tincture of the chloride of iron, &c. These cases are apt to recur from time to time, and I am convinced that most of those suffering with this disease will never again be fit for active service. Fortunately their number is small.

Extract from the Report of Surgeon Nath. W. Leighton, 173d New York Volunteers, *to* Medical Inspector George W. Stipp, U. S. A. *Franklin, Louisiana, February* 12, 1864.

The 173d New York, which was recruited in the cities of Brooklyn and New York, embarked at Riker's Island, New York, December 7, 1862, and went on transports to Baton Rouge, Louisiana. It has been ever since in the department of the Gulf. Altogether the most prevalent disease has been malarial fever of the intermittent type. This assumed a graver form during the months of July and August, 1863, than at any other period, even those who had but two or three paroxysms being left so debilitated as sometimes to be weeks in regaining their appetite and strength. Many were sent to general hospital, in the majority of whom the disease had assumed a continued type, and should have been reported as typho-malarial. Diarrhœa and dysentery were very prevalent from the 1st of March to the last of August, and forty-two cases of scurvy were reported during August and September. Altogether four hundred and twenty-nine cases of diarrhœa and dysentery occurred during the year 1863. There were also ninety-four cases of rheumatism. The strength of the regiment when it left New York was seven hundred and seventy-four officers and men.

Extract from the Report of Medical Inspector George W. Stipp, U. S. A. *Department of the Gulf, May*, 1864.

The result of observations in this department would show that those who use rations of pork for any considerable time have suffered from diarrhœa more than those who did not make use of it. * * * It has been confidently affirmed by some that diarrhœa, so extensively prevalent in the warm season, in Louisiana particularly, is developed by eating salt pork habitually. Perhaps, were it taken with other meats, or accompanied by a variety and abundance of vegetables, no such manifestations would occur.

Extract from the Report of Surgeon David Wooster, 5th California Volunteers. *Camp Union, near Sacramento, California, January* 13, 1862.

I have treated our cases of diarrhœa with laxatives, followed by anodynes. To those that lasted more than three days under this treatment I gave fifteen grains of blue mass and ten of subnitrate of bismuth at one dose. There has not been a case in which the cure has not been complete. A dose of some mild laxative is sometimes required the second or third day to relieve the constipation which occasionally follows. Neither the bismuth nor the blue mass alone will answer. I have tried each in several consecutive cases without success.

Section III.

FATAL CASES OF DIARRHŒA AND DYSENTERY, WITH ACCOUNTS OF THE MORBID APPEARANCES OBSERVED.

This Section will include, as far as possible, all the accounts of fatal cases of diarrhœa and dysentery in which the morbid appearances were recorded, with the exception of the few given in connection with special reports in the last section, and those belonging to the illustrations of the pathological anatomy of these diseases presented in Section IV. These cases have been collected from the monthly reports of sick and wounded, the medical descriptive lists, and the case-books of the general hospitals, which were turned in to the Surgeon General's Office after the close of the war.

The medical descriptive lists were first ordered to be used in 1862. The forms issued were printed on foolscap paper; in the heading blank spaces were left for the insertion of the name of the hospital, number of the ward or bed, name, age, rank, company and regiment of the soldier, nature of the disease or injury, the result and its date; the rest of the sheet was divided into four columns, headed, respectively, date, treatment, diet, remarks as to condition of patient, &c.; the first and third columns were narrow, the second and fourth as wide as the paper would permit. The form is reproduced in the Introduction to the First Surgical Volume, page XVII. On each blank the following note was printed: "Note.—When a patient is first received into a General Hospital, the entries on this descriptive list will be commenced. All important changes in his condition will be noted on it, in ink, from time to time, by the surgeon in charge of the ward. When the patient has been wounded, the date and character of the wound will be stated, the nature of the operation, if any, and, above all, the result. In case of transfer, this list will be sent, through the officer in charge of the transportation, or failing one, by mail, to the surgeon in charge of the hospital receiving the patient. When this medical history shall have been completed, by the cure, discharge, furlough, or death of the patient, it will, with the treatment and result carefully noted, be transmitted directly to the Surgeon General."

The intention was that the medical descriptive list, like the military descriptive list, should accompany the soldier in his movements from station to station. It was supposed that this would answer a useful purpose, by informing the medical officer, to whose care any patient might be transferred, of the previous history of the case. After the termination of cases in death, discharge for disability, or recovery, the descriptive lists were to be forwarded to the Surgeon General's Office, and it was hoped they would form a valuable source of information with regard to the nature and treatment of the diseases of soldiers. These expectations were very imperfectly realized. The multitude of the sick and wounded as compared to the number of medical officers, and the numerous transfers from hospital to hospital, seemed to render it impossible to fill up the descriptive lists for all hospital patients as originally designed. They were never at any time used in all the

hospitals, and even where most extensively employed were only filled up for a small portion of the patients. As a means of informing medical officers of the previous history of cases, they proved a total failure, for they were never sent with any number of the sick from hospital to hospital. They were, however, employed to a limited extent for the purpose of recording brief histories of cases for transmission to the Surgeon General. Some thousand medical cases reported on these blanks are on file in the Surgeon General's Office. The great majority of them are so meager as to have little if any value. A certain number, however, especially those referring to fatal cases in which autopsies were made, are more complete, and these have been selected for publication in this and subsequent chapters.

The medical regulations in force at the commencement of the war directed the senior medical officer of each hospital, post, regiment, or detachment to keep and deliver to his successor a prescription-book, a diet-book, and a case-book.* In the first two the prescriptions and diet ordered for each patient were to be recorded daily. The case-book was reserved for a fuller account of the more important cases. The pressure of other duties, and the contempt of the majority of the newly appointed officers for what it soon became fashionable to call "red tape," led, from the first, to the neglect of the prescription and diet books, which, in most instances, were imperfectly kept, and in many hospitals not kept at all. The case-books, fortunately, were not altogether neglected, though it must be admitted that surgical cases claimed the greater part of the attention bestowed upon them. After the close of the war the Surgeon General ordered that the books and records of the hospitals about to be broken up should be sent to his office for preservation, and among them several hundred more or less valuable case-books were received and are now on file. The original records of very many of the most valuable cases previously reported on the medical descriptive lists and otherwise, were found in these case-books, with numerous other cases which had never previously been reported. Some of these books appear to have been kept with considerable care; others are slovenly, and bear internal evidence that the entries were made by careless subordinates. All have been thoroughly examined, and whatever seemed of value made use of. Where the case was previously reported, the case-book has been preferred as authority, except where there seemed to be some good reason for a different course. All the cases given in this section are derived from the case-books of the several hospitals named, except when it is otherwise specified.

The cases of diarrhœa and dysentery here presented will be grouped by the hospitals in which they occurred; and those belonging to each hospital will be arranged simply in the order of the date of the termination of each case. Originally it was proposed to arrange the cases in groups corresponding to the several varieties of diarrhœa and dysentery, without regard to time or place; but while this plan offered some advantages, it would have scattered the cases collected by individual observers, and would have excluded many cases which are not recorded in sufficient detail to permit them to be classified with certainty. On the whole, therefore, the simpler plan which has been adopted seemed preferable. Whenever it could be ascertained, the name of the medical officer reporting each case is appended to it.

Perhaps it may be thought that many of the cases given are so fragmentary that they might have been omitted with advantage; but even fragmentary reports often serve as

* Revised Army Regulations of 1861, par. 1254.

additional evidence in confirmation of particular facts or opinions, and the editor has considered it his duty to present, as far as possible, all the evidence on record, desiring to give as complete a picture of these diseases as could be drawn from the material at his disposal, and being willing to bear the imputation of having admitted unimportant cases rather than risk the chance of excluding any of value.

The following case is extracted from the case-book of BAXTER HOSPITAL, Burlington, Vermont, Acting Assistant Surgeon Samuel W. Thayer in charge:

CASE 93.—Private Calvin Washburn, company K, 2d Vermont volunteers; admitted February 12, 1864. Chronic diarrhœa. [This man appears on the regimental returns of the 2d Vermont as taken on sick report, January 1, 1864, with chronic diarrhœa. The disease resisting treatment, he was admitted, February 2d, to Emory hospital, Washington, D. C., where he was treated for the same disease, and thence transferred to this hospital.] At the time of admission he was very much emaciated. He stated that he had suffered from chronic diarrhœa about six months, but had improved very much while in hospital in Washington. His pulse was feeble; his tongue pale. Ordered a nutritious diet and stimulants. He apparently continued to improve, and had a good appetite. About midnight, March 29th, the attending surgeon was summoned and found him complaining of a severe pain in the abdomen, respiration hurried, pulse rapid and feeble. Gave quarter of a grain of sulphate of morphia and stimulants. Died March 31st, at 8 o'clock P. M. *Autopsy* twelve hours after death: The cavity of the thorax contained a large quantity of serum. There were pleuritic adhesions on the right side. Both lungs were filled with tubercles. The liver was somewhat softened, and a cyst was found in the lower portion of its right lobe. The colon was extensively ulcerated and nearly eaten through in two places.

The two following cases were forwarded, on medical descriptive lists, from the KNIGHT HOSPITAL, New Haven, Connecticut, Surgeon Pliny A. Jewett, U. S. V., in charge:

CASE 97.—Private Lyman K. Stearns, company D, 14th Connecticut volunteers; age 35; admitted by transfer from Harewood hospital, Washington, D. C., February 12, 1865. Chronic diarrhœa. [The register of the regimental hospital of the 14th Connecticut volunteers shows that this man was admitted to that hospital September, 1863, for acute diarrhœa, and sent to Culpepper Court-House, Virginia, September 24th. He next appears on the register of the hospital of the 2d Division, 2d Army Corps, admitted December 8, 1864; debility. Sent to depot hospital of the 2d Corps, December 15th. The register of the depot hospital of the 2d Corps records him admitted December 15th; remittent fever. Sent to Washington, D. C., January 17, 1865. The register of Harewood hospital, Washington, records him admitted January 18th; chronic diarrhœa. Sent to New Haven February 10th.] The patient had been sick about six months. He was much emaciated, very feeble, and had from four to eight thin stools daily. Was treated with astringents and opiates, tonics, nourishing diet, and stimulants. He gradually sank, and died March 16th. *Autopsy* nineteen hours and a half after death: Rigor mortis slight. Great emaciation. The brain was not examined. The heart and lungs were free from disease. The omentum was a mere sheet of thin membrane with no fat anywhere. The extremity of the vermiform appendix was adherent to the peritoneum just under the umbilicus; there were also adhesions in the vicinity of the caput coli. The sigmoid flexure of the colon was found in the left hypochondriac region. The left kidney was found reposing directly upon the promontory of the sacrum, and its hilum was found upon its upper anterior surface; the renal arteries supplying it came off from the bifurcation of the aorta, and consisted of four branches. The spermatic arteries also were lower down than usual, arising about an inch above the bifurcation of the aorta. The right kidney was normal in size and position. The spleen was very small and corrugated. The liver healthy, but small. The whole extent of the mucous lining of the intestine was soft and thin. In the cæcum and ascending colon there were numerous nearly circular patches of ulceration, and a deposit of pseudomembrane.—Acting Assistant Surgeon W. B. Casey. [Nos. 524 and 525, Medical Section, Army Medical Museum, are from this case. No. 524 is a portion of the colon coated with pseudomembrane, and presenting a few superficial ulcers. No. 525 is the left kidney, with the bifurcation of the aorta and the renal arteries. The hilum of the kidney is situated in the upper part of its anterior surface. From the aorta, at its bifurcation, three arteries go to this kidney, one of which bifurcates, so that four renal arteries enter the substance of the gland—two at its pelvis, the others on its superior edge.]

CASE 98.—Sergeant George H. Brown, company B, 31st United States colored troops; age 22; admitted by transfer from another hospital January 3, 1865. Consumption. This man presented all the signs of tubercular phthisis, and had also a severe diarrhœa. He was put upon the use of cod-liver oil and whiskey, and received three or four times a day a pill containing one grain each of sulphate of iron and opium, one-tenth of a grain of ipecacuanha, and one-twentieth of a grain of strychnia. His stomach soon became irritable and rejected all food. He became emaciated, and died April 11th at 11 A. M.—Acting Assistant Surgeon D. L. Daggett. *Autopsy* twenty-four hours after death: Body very much emaciated. Brain not examined. The upper lobes of both lungs were thickly studded with tubercles. In the right lung there were three cavities large enough to contain three or four teaspoonfuls of fluid. There were old pleuritic adhesions on the right side, recent pleuritic adhesions on the left side. The left pleural sac was filled with serum. The omentum was observed to be very thin and devoid of fat, but thickly studded with tubercles. The mesenteric glands were enlarged and tubercular. There were a number of tubercular ulcers in the ileum, and the colon was also ulcerated. The liver, spleen, kidneys and stomach presented no unusual appearances.—Acting Assistant Surgeon W. B. Casey. [Nos. 551 and 552, Medical Section, Army Medical Museum, are from this case. No. 551 is a portion

of the ileum taken from just above the ileocæcal valve, on the mucous surface of which are a number of tubercular ulcers. On the peritoneal surface, opposite to the principal ulcer, are several minute tubercles. No. 552 is a portion of the mesentery with several feet of the ileum attached. The mesenteric glands are enlarged. On the peritoneal surface of the ileum are a number of little groups of minute tubercles, which, by transmitted light, are seen to correspond in position to ulcers on the mucous membrane.]

The three following cases were forwarded on medical descriptive lists from the TROY HOSPITAL, New York, Surgeon George H. Hubbard, U. S. V., in charge:

CASE 99.—Private Walter Marshall, company K, 93d New York volunteers; age 38; admitted November 18, 1864. Chronic diarrhœa. [This man was admitted to regimental hospital July 21, 1864, and was returned to duty July 24th. September 3d he was sent to the field hospital of the 3d Division, 2d Army Corps, suffering from diarrhœa. September 15th he was transferred to the depot hospital of the same division at City Point, Virginia, whence, September 19th, he was sent to Washington. September 21st he was admitted to Emory hospital, Washington, D. C., where he was treated for diarrhœa until November 1st, when he received a furlough and went to his home. While on furlough he was taken worse, and was admitted to this hospital.] He stated that he had suffered from diarrhœa for four months. He is now very much emaciated and debilitated; the expression of his face is anxious, there is a hectic flush on each cheek, and the eyes are suffused; pulse small and feeble; respiration 25; skin dry and harsh; tongue coated with a yellowish-white fur. There is total loss of appetite, great thirst, and some nausea. The abdomen is slightly tympanitic, and there is some tenderness over the transverse colon, but no pain. He has ten or twelve dark, offensive dejections daily. From the date of admission this case steadily progressed to a fatal termination. The only apparent improvement under treatment was in the number of the discharges, which became less and less frequent, so that at last he had but about two dejections daily. Forty-eight hours before death a high fever came on. He died December 2d. He was treated successively with pills of blue mass, opium, and ipecacuanha; pills of persulphate of iron, opium, and quinine; aromatic sulphuric acid and laudanum, acetate of lead and opium, nitrate of silver and opium, chalk-mixture, &c.; milk-punch, egg-nog, &c. *Autopsy:* There was an intussusception of the ileum six inches in length. The mucous membrane of the rectum was very much thickened, indurated, and extensively ulcerated. The mesenteric glands were enlarged.—Acting Assistant Surgeon Myron J. Davis.

CASE 100.—Sergeant John Hardy, company I, 125th New York volunteers; age 37; admitted from David's Island, New York harbor, November 30, 1864. Chronic diarrhœa. He stated that five months ago, while on the march to Petersburg, Virginia, he was taken sick with diarrhœa. He remained with his regiment ten weeks, most of the time performing duty. He was then sent to hospital at City Point, Virginia, where he was admitted August 13th, having ten to twelve dejections daily. From City Point he was sent to David's Island, where he was admitted August 25th, and thence to this hospital. He is now very much emaciated and debilitated; the expression of his face is anxious, eyes bright, pulse 90, small and feeble; skin dry and harsh; tongue red, papillæ prominent. He complains of pains in the hypogastric region; his appetite is poor; he has some thirst. There is tenderness on pressure in the right iliac region and along the course of the transverse colon; the abdomen is flat. He has twelve dejections daily, which are dark and offensive. He has pain and difficulty in passing his urine. Ordered ten grains of Dover's powder to be taken at 8.30 P. M., and to be repeated half an hour after. Diet: Boiled milk. December 1st: Condition unchanged. To take five grains of tannin and quarter of a grain of opium four times daily; an egg with an ounce of sherry wine at 10 A. M. and 3 P. M.; fifteen ounces of milk-punch during the day. December 2d: Had eight dejections during the last twenty-four hours. Substitute five grains of citrate of iron and quinia three times a day for the tannin and opium. Diet and wine as before. A drachm of solution of morphia at bed-time. December 3d: Had eight dark, offensive stools during the last twenty-four hours. Treatment continued. December 5th: Did not rest well last night; is despondent; pulse feeble; has some fever; complains of pain in the hypogastric region and over the transverse colon; no appetite; had twelve stools in the last twenty-four hours. Stop the citrate of iron and quinia, and substitute pills containing each three grains of persulphate of iron, one of quinia, and quarter of a grain of opium. One to be taken four times a day. Milk-punch, egg and sherry wine continued. Solution of morphia at bed-time as before. December 8th: Was rather better for a day or two, but is again somewhat worse. Substitute for the pills a chalk-mixture containing tincture of opium and tincture of catechu; renew the citrate of iron and quinia. Morphia at bed-time, and diet as before. December 9th: Is much more comfortable; stools less frequent. Treatment continued. December 10th: Remains comfortable. Treatment continued. December 11th: The diarrhœa is worse again. Complains of severe pain in the umbilical region. Substitute pills containing quarter of a grain each of sulphate of copper and opium and one grain of quinia. One to be taken four times a day. Morphia at bed-time, and diet as before. December 12th: Is feeling better; takes his food; had twelve stools in the last twenty-four hours. Continue the pills, but take ten grains of tannin and one of opium at bed-time, instead of the morphia. December 15th: Had eight stools in the last twenty-four hours. Treatment continued. December 16th: Is not feeling so well; dejections more frequent. Treatment continued. December 17th: Is feeling badly; face sunken, pulse feeble, skin hot and dry; complains of pain in the umbilical region; tongue dry, cannot take food; had fourteen stools in the last twenty-four hours. Treatment continued, with the addition of the following: ℞. Acetate of lead six grains, powdered opium two grains; make two pills. To be taken during the night. December 18th: Is a little more comfortable. Treatment continued. December 19th: Seems to be sinking, can hardly get him to take food; had twelve dark, offensive stools in the last twenty-four hours. Treatment continued. Mutton broth. December 20th: Has severe pain in the umbilical region. Treatment continued. Apply a blister over the seat of pain. December 22d: Is looking and feeling better, takes food, is free from pain; had six stools in the last twenty-four hours. Treatment continued, with the addition of enemata of laudanum. December 23d: Is looking brighter; rested well last night; pulse 90, small and feeble; takes food; had six stools in the last twenty-four hours. Treatment continued. December 24th: Six stools in the last twenty-four hours. Treatment continued, with the addition of four grains of sulphate of zinc in each enema. December 30th: Is not feeling quite so well,

did not rest well last night, expression of face a little anxious, features sharp, pulse 90 and feeble, skin warm and moist; complains of pain in the epigastric and umbilical regions; vomited twice last night; takes food and stimulants; had eight dark, offensive stools in the last twenty-four hours. Treatment continued. Apply a blister over the seat of pain. December 31st: Can hardly speak above a whisper, face sunken, eyes rolled up; lies on his back: pulse small and feeble; complains of a smarting pain extending from the fauces to the stomach, tongue dry, cannot get him to take food, vomited four times last night; had fifteen stools in the last twenty-four hours. Treatment continued. January 1, 1865: Is unconscious, extremities cold; seems to be sinking rapidly. Revived somewhat toward evening and regained consciousness. January 2d: Is quite rational this morning, expression of face natural, pulse 90, small and feeble; skin cold; has no pain; is inclined to sleep most of the time; tongue dry and coated; had three stools in the last twenty-four hours. Substitute for former treatment pills containing one grain of acetate of lead, quarter of a grain of opium, and two-thirds of a grain of ipecacuanha; one to be taken every three hours; whiskey. January 3d: Has not had any passage during the last twenty-four hours; left leg and foot œdematous. Treatment continued. Died, January 4th, at midnight. *Autopsy:* Body very much emaciated. The mucous membrane of the ileum looked as though it had been coated with dirty varnish; it was not ulcerated. The mucous membrane of the ascending, transverse, and descending colon and rectum was indurated, thickened, and thickly studded with large ulcers extending from the cæcum to the verge of the anus. The mesentery was highly congested, and the mesenteric glands were slightly enlarged and indurated.—Acting Assistant Surgeon M. J. Davis.

CASE 101.—Private Hiram Longendyke, company F, 7th New York heavy artillery; age 30; admitted December 2, 1864. Chronic diarrhœa. [The records of the field hospital 1st division, 2d Army Corps, show that this man was admitted to that hospital June 25, 1864. The diagnosis was rheumatism. He was thence transferred to the depot hospital of the same division, City Point, Virginia, where he was admitted July 5th—diagnosis not recorded. From thence he was sent to New York harbor, and was admitted to the hospital on Blackwell's Island, August 1st, as a convalescent. August 11th, was sent on furlough for thirty days, and on November 30th he was transferred to the McDougal hospital, Fort Schuyler, New York harbor, where the diagnosis recorded is chronic diarrhœa. December 1st, he was sent to this hospital, and admitted at the date above given.] Acting Assistant Surgeon A. W. Holden reports that he first saw the patient December 7th. He was then much emaciated, his countenance pinched and haggard, his lips parched and dry, the tongue covered with a whitish fur; abdomen sunken and sensitive to the lightest pressure; pulse about 90, weak and irritable. He stated that he had suffered from diarrhœa for a long time. He is using the following prescription, which was ordered to be continued: ℞. Subnitrate of bismuth two drachms, sulphate of quinia twelve grains, sulphate of morphia three grains; make twelve powders. Take one three times a day. December 11th: The general condition of the patient is unchanged. He has from ten to fifteen dejections daily. The stools are thin, in part slimy, in part feculent, and are accompanied by tenesmus. The patient complains of pain in the left lung. He has a cough and slight expectoration. Continue treatment; also the following cough-mixture: ℞. Syrup of squill, camphorated tincture of opium, of each two ounces, fluid extract of ipecacuanha one drachm. Take a teaspoonful three times a day. December 20th: The patient appears to be gradually failing. The diarrhœa is worse, and is accompanied by a good deal of tormina. Omit the cough-mixture; continue the bismuth powders: also tincture of the chloride of iron three times a day. The patient continued to grow feebler, and his diarrhœa resisted treatment. December 24th, the case was transferred to the charge of Dr. McLean, who next day prescribed pills containing each a quarter of a grain of sulphate of copper, half a grain of opium, and a grain of sulphate of quinine; one to be taken every four hours. An ounce of sherry wine three times daily. The diarrhœa, however, continued unchecked, and the patient died January 8, 1865. *Autopsy* fifteen hours after death: The large intestine alone was examined; its mucous membrane was thickened, and, in the sigmoid flexure and rectum, ulcerated.—Acting Assistant Surgeon L. R. McLean.

The four following cases were forwarded on medical descriptive lists from the DECAMP HOSPITAL, David's Island, New York harbor. Acting Assistant Surgeon James W. Dickey in charge at the date the first case was forwarded, and Assistant Surgeon J. Sim Smith in charge at the date of the other cases.

CASE 102.—Private Christopher McEnleer, company K, 1st United States artillery; age 26; admitted May 12, 1863. Chronic diarrhœa. [This man was admitted to Armory Square hospital, Washington, D. C., April 22, 1863, with chronic diarrhœa, and sent to New York on May 5th. May 6th, he was admitted to the Convalescent hospital, Fort Wood, Bedloe's Island, New York harbor, whence he was transferred to this hospital at the date above given.] The patient stated that he had been troubled with diarrhœa about eight months. He has now from four to six passages a day. Ordered five grains of extract of logwood three times a day; rice-water for drink. After a week or two, as the diarrhœa continued unabated, injections of laudanum and sulphate of zinc were directed, with the effect of diminishing the stools to from one to three daily. The patient improved in strength and was able to walk out quite frequently. June 15th: Injections continued. July 1st: The stools are again more frequent, although the injections have been given regularly. The patient is evidently failing. Died, July 7th. The injections were continued till the day of his death. *Autopsy:* Some indications of inflammation were found in the right lung and kidney, and also in the posterior portion of the right lobe of liver. The small intestines were found to be much ulcerated. [The condition of the large intestine is not recorded.]—Acting Assistant Surgeon James W. Dickey.

CASE 103.—Private George H. Banker, company K, 118th New York volunteers; admitted November 3, 1863. Chronic diarrhœa. [According to the records of the Hampton hospital, Fortress Monroe, Virginia, this man was admitted to that hospital September 10, 1863, suffering with intermittent fever. October 20th he was transferred to New York, and November 2d he was admitted to Convalescent hospital, Fort Wood, Bedloe's Island, New York harbor, whence he was transferred next day to this hospital.] The first notes were taken November 10th. The patient stated that nine weeks ago he was seized with chills and fever,

and three weeks after, while convalescing, was attacked with profuse diarrhœa, which has lasted ever since. About a month ago he began to be troubled with a cough. He says he was improving somewhat when he went upon the transport to come north, but became worse on the way. When admitted he was very weak and much emaciated. At present his stomach is irritable; his pulse 110 and weak; he has very little appetite; there is dulness on percussion on the right side, with roughened inspiration and prolonged expiration; on the left side some fine rales are heard. Ordered a grain of quinine every three hours. Diet: Eggs, beef-tea, and milk. November 11th: Is very weak, and evidently failing rapidly; pulse 120 and very weak; tongue dry; diarrhœa profuse, with dyspnœa to such an extent that he is unable to lie down. Treatment continued. November 12th: Ordered half an ounce of whiskey and one grain of carbonate of ammonia every hour. He died November 12th, at 12.30 p. m. *Autopsy* twenty hours after death: Body much emaciated. Brain not examined. At the apex of the right lung there were three or four small deposits of tubercle with solidified tissue about them. The left lung was much congested, but contained no tubercles. The heart was normal. The intestines were nowhere ulcerated, though nearly the whole tract was much congested, particularly about the ileocæcal valve. The kidneys were normal.—Acting Assistant Surgeon A. Norton Brockway.

CASE 104.—Private John Finnarty, company H, 99th New York volunteers; age 21; admitted November 3, 1863. Bright's disease. The patient stated that he had enjoyed good health until three months ago at Yorktown, where he was taken sick with intermittent fever, which continued about twenty days; while he was convalescing he was attacked with diarrhœa and a severe pain in his left side. The diarrhœa has continued until the present time, averaging four or five passages daily. The pain in the side abated soon. He does not give a clear account of the chest trouble, but mentions that besides the pain he has had dyspnœa and cough for some time. He was sent to Hampton hospital, Fortress Monroe, where he remained, gradually losing flesh and strength until he was transferred to this hospital. [The records of Hampton hospital show that he was admitted September 8th, with intermittent fever, and sent to New York October 30th.] At present he is weak and anæmic; his pulse is frequent and feeble; the stools are loose but not painful; his legs are œdematous. His urine was tested with nitric acid and heat and found to contain albumen. He has also some cough, which does not seem to trouble him very much. November 14th: The cough is more troublesome. On auscultation found total loss of respiratory murmur on the left side, and on the right side coarse rales, sometimes bubbling, were heard both during inspiration and expiration. There is flatness on percussion over the left side except at the extreme apex of lung. On the right side percussion gives nearly normal resonance. The heart-beats are felt on the right side very near the nipple. His diarrhœa continues unchecked. The treatment has consisted, since admission, of quinine and iron, with milk, eggs, and beef-tea; he has also had half an ounce of whiskey every two hours. November 18th: All the symptoms continued unabated; the pulse is 100 and feeble. November 21st: The diarrhœa is very profuse, the dyspnœa urgent; he is evidently failing. November 23d: Applied cups to the chest to relieve pain and dyspnœa. November 24th: The dyspnœa is so great that he tries to sit up, but can only do so a little while at a time; pulse 120 and very weak; legs and face œdematous. Applied turpentine stupes to the chest; half an ounce of whiskey every hour. Died, November 25th. *Autopsy:* The left side of the chest was filled with pus, the quantity being estimated at a gallon. The left lung was collapsed, very small, and firmly adherent to the spinal column and ribs; it was filled with tubercles. The left side of the chest was lined by a pyogenic membrane, which was very firmly adherent to the thoracic parietes. The right lung had small tubercles scattered through its substance. The heart was normal except as to position, being pushed over to the right side. The liver was considerably congested. The kidneys were enlarged and fatty, and their capsules peeled off very easily. [The condition of the intestinal canal is not recorded.]—Acting Assistant Surgeon A. Norton Brockway.

CASE 105.—Private Henry Pitsley, company C, 147th New York volunteers; age 21; admitted October 29, 1863. Chronic diarrhœa. [This man was admitted to the field hospital of his regiment in the latter part of March, 1863, and returned to duty some time after; the date is not recorded. He was re-admitted with dysentery May 15th, and is reported returned to duty May 18th. He was again admitted with diarrhœa October 1st, and transferred to the field hospital of the 1st Division, 1st Corps, October 5th. October 11th he was sent to Washington, D. C., and was admitted on the same day to Carver hospital. The diagnosis recorded is chronic diarrhœa. October 28th he was sent to New York, and admitted to this hospital next day, as stated above.] He stated that he was attacked about five months ago with diarrhœa and pain in the side. The diarrhœa was profuse and the pain in the side severe, but he was kept with his regiment until about two weeks ago, when he was sent to Carver hospital, Washington, D. C., whence he was transferred to this place. He is now much emaciated and very weak; pulse frequent and feeble; diarrhœa profuse. He has considerable cough, which he says has troubled him for the last four months. November 3d: The patient appears to be gaining strength; the diarrhœa is somewhat improved, there being but about four passages daily; his appetite also has improved. Ordered half an ounce of whiskey every two hours, and a chalk-mixture containing paregoric and rhatany. Diet: Milk, eggs, and beef-tea. November 12th: Is about out of doors, and seems to be doing very well. Treatment continued, with the addition of half an ounce of cod-liver oil twice daily. November 25th: The patient is still doing well. He has gained some flesh, but the cough and diarrhœa continue, though they are less troublesome than at first; his appetite is good, and he sleeps pretty well at night. Treatment continued. November 30th: For the last day or so the patient has not been so well. He is beginning to lose appetite; his cough is troublesome, and the diarrhœa is again very severe; does not sleep well at night. Directed him to take ten grains of subnitrate of bismuth and one-third of a grain of powdered opium every three hours. December 3d: The diarrhœa still continues; the patient is very feeble. Ordered a pill of lead and opium every three hours; whiskey. He died December 5th. *Autopsy* eighteen hours after death: Rigor mortis well marked; body very poorly nourished. The left lung was tuberculous and firmly adherent to the walls of the chest; its upper lobe was nearly solidified, and riddled with cavities, one or two of which measured an inch in diameter; the lower lobe contained tubercles but no cavities; in the right lung some groups of tubercles were scattered here and there, but there were no cavities. The heart was normal. The diaphragm was firmly adherent to the whole upper surface of the liver. The liver and spleen were normal. About the ileocæcal valve there was marked congestion, and there were deposits of tubercles [?] on the surface of the intestines, but no well-marked ulceration. The mesenteric glands were tubercular; some of them were as large as an inch and a half in diameter. The kidneys were normal.—Acting Assistant Surgeon A. Norton Brockway.

The three following cases are from the case-book of McDougal Hospital, Fort Schuyler, New York harbor, Assistant Surgeon Havilah M. Sprague, U. S. A., in charge.

Case 106.—Private Steward D. Middaugh, company C, 109th New York volunteers; age 18; admitted from Washington, D. C., June 22, 1864. Chronic diarrhœa. [The records of Mount Pleasant hospital, Washington, D. C., show that this man was admitted June 15th from the field hospital of the 9th Army Corps, White House Landing, Virginia. The diagnosis on the register is convalescent from typhoid fever. He was sent to New York June 21st, and admitted to this hospital at the date given above.] He stated that he had been sick three months. For three days before death he had clonic spasms, lasting from three to ten minutes at intervals, during which consciousness was interrupted, and the heart's action was hurried, feeble, and irregular. He died August 11th, during one of these spasms. *Autopsy* eight hours after death: The thoracic viscera, liver, spleen, and kidneys were normal. The mucous membrane of the stomach was softened. Both small and large intestines were congested, inflamed, and ulcerated. [There is no record of any examination of the brain or spinal cord.]

Case 107.—Corporal William C. Hull, company E, 16th Pennsylvania cavalry; age 27; admitted August 7, 1864. Dysentery. [The records of the Cavalry Corps hospital, City Point, Virginia, show that this man was admitted to that hospital July 13th, suffering from diarrhœa. August 5th he was sent on board the hospital transport Atlantic and brought to this hospital.] Treatment: Tonics, astringents, and stimulants; careful diet. Died, August 16th. *Autopsy* seven hours after death: Rigor mortis moderate; body much emaciated. The heart, lungs, liver, spleen, pancreas, and kidneys were normal. The lower half of the ileum and the colon were much congested, inflamed, and thickened; the mucous coat softened and ulcerated.

Case 108.—Private Edward Sweeney, company C, 48th Pennsylvania volunteers; age 45; admitted August 7, 1864. Diarrhœa. [The records of the depot field hospital, 2d Division, 9th Army Corps, show that this man was admitted to that hospital, August 2d, with diarrhœa; sent on board the hospital transport Atlantic August 5th, and brought to this hospital.] He had been ill about a month; had constant diarrhœa, and a yellow furred tongue. Died, August 17th. *Autopsy* one hour after death: Rigor mortis well marked. The right lung was adherent to the thoracic parietes. The heart was healthy. The liver was normal. The kidneys were large. The mucous membrane of the intestines was congested and ulcerated.

The next eight cases are from the case-book of Ward Hospital, Newark, New Jersey, Assistant Surgeon J. Theodore Calhoun, U. S. A., in charge.

Case 109.—Private Philip Soukil, company A, 8th New Jersey volunteers; admitted January 16, 1865. Chronic diarrhœa. [The records of the depot field hospital of the 2d Army Corps, City Point, Virginia, show that this man was admitted December 7, 1864, for chronic diarrhœa. December 12th he was sent on board the hospital transport Connecticut and carried to Washington, D. C. December 13th he was admitted to Harewood hospital; diagnosis chronic diarrhœa. December 24th he was sent to his home on furlough; being too sick to return, he was admitted to this hospital at the date given above, by order of the medical director.] Died, January 17th. *Autopsy* thirteen hours after death: The large intestine alone was examined. In the cæcum and ascending colon the walls of the gut were very much thickened and very vascular, and the same characteristics were observed in the descending colon and sigmoid flexure. The transverse colon was not thickened, but presented some patches of adherent lymph. The solitary glands in the descending colon were much enlarged. No ulcers were found.—Acting Assistant Surgeon Joseph D. Osborne.

Case 110.—Private Nelson Maloney, company H, 3d New York cavalry. Admitted June 3, 1864. Diarrhœa and incipient phthisis. [The records of the depot hospital of the Cavalry Corps of the Army of the Potomac, City Point, Virginia, show that this man was admitted to that hospital May 16th, with chronic diarrhœa. He was sent to Washington on May 24th. The records of Lincoln hospital, Washington, D. C., show that he was admitted to that hospital May 25th; diagnosis typhoid fever. He was transferred from Lincoln hospital June 2d, and admitted to this hospital at the date above given.] He was ordered to be discharged from service on surgeon's certificate of disability, March 7, 1865, but died March 9th, while waiting for his papers. *Autopsy* ten hours after death: Body emaciated; skin dark and dingy. The lower lobe of the left lung was filled with a dark, purulent fluid, which exuded on slight pressure, leaving small cavities. The left pleural sac contained a quantity of dark pus. The right lung was filled with frothy serum. The heart and pericardium were normal. The blood was dark colored and fluid, no coagula being found anywhere. The stomach and intestinal canal appeared to be normal. The liver was yellow, with a tinge of brown in some parts. The kidneys were anæmic, and increased in size and weight.—Acting Assistant Surgeon Milton Baldwin.

Case 111.—Corporal William H. H. Vosburg, company F, 16th Wisconsin volunteers. Admitted April 24, 1865, from North Carolina. Varicose ulcers of the left leg. [The register of the regimental hospital of the 16th Wisconsin volunteers shows that this man was treated in that hospital from September 29th to October 3, 1864, for a scorbutic ulcer. The register of the 3d Division hospital, 17th Army Corps, shows that he was admitted to that hospital April 9, 1865—diagnosis ulcer—and transferred to the Foster hospital, Newbern, North Carolina, where he was admitted April 13th; thence he was transferred to this hospital.] Died, May 8th, with symptoms resembling those of typhoid fever. *Autopsy* five hours after death: The heart was in a normal condition. The lungs were congested. The liver was enlarged, soft, and easily torn. The spleen was nearly double its natural size. The transverse and the upper portion of the descending colon were inflamed for a space about six inches in length, the inflammation extending through to the peritoneal covering and involving a portion of the omentum, which was congested. The intestines were distended by a large quantity of thin, yellowish fæcal matter, which was not unusually offensive. Nothing abnormal was found in the small intestine.—Acting Assistant Surgeon E. P. Nichols.

Case 112.—Corporal Nils Swanson, company D, 57th Illinois volunteers; admitted April 24, 1865, from North Carolina. Chronic diarrhœa. [The records of the regimental hospital of the 57th Illinois volunteers show that this man was treated in

that hospital for chronic diarrhœa during the month of March, 1865. The register of the 4th Division hospital, 15th Army Corps, shows that he was admitted to that hospital April 7th, and sent to Beaufort, North Carolina, April 10th. The records of the Mansfield hospital, Beaufort, show that he was admitted to that hospital April 11th as a convalescent, and transferred to the north April 19.] Died, May 16th. *Autopsy* fifteen hours after death: There was some rigor mortis; body greatly emaciated. The lungs, heart, liver, and kidneys were normal. The large intestine was ulcerated throughout its whole extent. The small intestine was congested. No immediate cause could be found for the sudden death of this man. A lesion of the heart was suspected, but was not found.—Acting Assistant Surgeon E. P. Nichols.

CASE 113.—Private William H. Osborne, company E, 174th Ohio volunteers; admitted April 24, 1865, from Beaufort, North Carolina. Chronic diarrhœa. [The register of the depot hospital of the 23d Army Corps shows that this man was admitted March 14, 1865, with pneumonia, and transferred to Foster hospital March 29th. From the Foster hospital he was sent to the Mansfield hospital, Beaufort, North Carolina, the register of which records him admitted as a convalescent April 4th, and sent north April 19th.] Died, June 8th. *Autopsy* twenty hours after death: Rigor mortis tolerably well marked; skin dingy; body considerably emaciated. The pericardium was greatly distended by a sero-purulent fluid. The muscular substance of the heart was flaccid and pale. Both lungs were dotted with small tubercles, and in the inferior lobes of each was a large abscess with fetid contents. The pleural sacs contained a considerable quantity of fluid similar in character to that contained in the pericardium. The stomach was normal. Both the small and the large intestines were slightly congested and considerably distended. The omentum was healthy. The liver was normal in size, but somewhat congested. The spleen was somewhat enlarged. The kidneys were normal.—Acting Assistant Surgeon William C. Karner.

CASE 114.—Private Cyrenus Giles, company G, 124th New York volunteers; admitted May 29, 1865. Chronic diarrhœa. [The register of the regimental hospital of the 124th New York volunteers shows that this man was treated for diarrhœa during September, 1864. The register of the 3d Division hospital, 2d Army Corps, shows that he was admitted to that hospital September 17th for diarrhœa, and sent to City Point, Virginia, October 22d. The register of the depot hospital, 2d Army Corps, City Point, records him admitted October 22d—diarrhœa—sent to another hospital November 1st. He was carried on the hospital transport Ben Deford to Alexandria, Virginia, where the register of the Fairfax Seminary hospital records him admitted November 2, 1864—chronic diarrhœa—transferred to another hospital April 25, 1865. There is no later record prior to his entry into this hospital.] Died, July 10th. *Autopsy* five hours after death: Emaciation extreme; considerable rigor mortis. The abdomen only was examined. The mucous membrane of the ileum was congested and presented patches of ulceration, but there was no enlargement of Peyer's glands. The mesenteric glands were enlarged. The liver and spleen were congested. The kidneys were fatty. One of the kidneys was surmounted by a body which seemed to be the suprarenal capsule, but was the size of an English walnut, and filled with a reddish-brown gritty substance. [The condition of the large intestine was not recorded.]—Acting Assistant Surgeon E. Holden.

CASE 115.—Private Barnard Ennis, company H, 8th New Jersey volunteers; admitted May 4, 1865. Chronic diarrhœa and bronchitis. [The records of the field hospital of the 3d Division, 2d Army Corps, show that this man was admitted to that hospital March 7th, suffering with chronic diarrhœa, and was transferred to the depot hospital of the same division at City Point, Virginia, March 15th. April 18th he was sent on board the hospital transport State of Maine, and transferred to Washington, D. C. The records of the Finley hospital, Washington, show that he was admitted April 20th—diagnosis chronic diarrhœa—and transferred to Newark, New Jersey, May 4th.] This man died July 25th, of hæmorrhage from the lungs. *Autopsy* same day: Rigor mortis well marked; extreme emaciation. Brain not examined. There was a large cavity in the upper lobe of the right lung, in which a clot showed the point from which the hæmorrhage took place. There was also a very large cavity in the same portion of the left lung. There were slight pleuritic adhesions on the right side, and very extensive ones on the left. The pericardium contained about two ounces of serum. The heart was healthy. The stomach and intestines were nearly normal; the latter showing very little to account for the long-continued chronic diarrhœa from which the patient had suffered.—Acting Assistant Surgeon Joseph D. Osborne.

CASE 116.—Private Evan Everly, company E, 4th Ohio volunteers; admitted from Harewood hospital, Washington, D. C., November 9, 1862. Diarrhœa. This man was convalescent from typhoid fever, but was still suffering from diarrhœa, and was much emaciated. [The register of Harewood hospital shows that he was admitted October 7th, but gives no diagnosis or disposition.] He died suddenly, at 6.15 P. M., December 10th. *Autopsy:* The right lung was healthy; the left lung was bound to the posterior walls of the thorax by firm adhesions. The heart was unusually small and pale; the right auricle and ventricle were almost empty, the left auricle and ventricle full of blood; the tricuspid and mitral valves were thickened and studded with vegetations. The stomach was distended by semi-fluid ingesta; its mucous coat was smooth and of a pale fawn color. The jejunum was intensely congested; the rest of the intestines was rather pale, but otherwise healthy. The liver was normal in size and structure, with the exception of a fissure an inch in length and about four lines deep, near the external border of the right lobe.

The next four cases are from the case-book of BEVERLY HOSPITAL, New Jersey, Assistant Surgeon Clinton Wagner, U. S. A., in charge:

CASE 117.—Private David Delano, company A, 13th Ohio cavalry; admitted September 28, 1864. Chronic diarrhœa. [The records of the depot hospital of the 9th Army Corps, City Point, Virginia, show that this man was treated in that hospital from August 22d to September 26th; diagnosis, acute diarrhœa.] Died, October 2d. *Autopsy:* Body very much emaciated. Nearly the whole extent of the intestine was congested, and there was extensive ulceration in the lower portion of the colon. The blood-vessels of the mesentery were engorged with blood, and the mesenteric glands were much enlarged.—Acting Assistant Surgeon George Johnson.

CASE 118.—Private Charles W. Farnum, company B, 32d Maine volunteers; age 30; admitted October 15, 1864. Chronic diarrhœa. [This man was taken sick with jaundice August 21th, and admitted to the field hospital of the 2d Division, 9th Army

Corps. He was suffering with chronic diarrhœa at the time. August 31st he was transferred to the depot hospital of the 9th Army Corps at City Point, Virginia, still suffering with diarrhœa. October 13th he was sent north to this hospital.] He died very suddenly, October 18th. *Autopsy:* A firm grayish-white clot was found in the left ventricle, extending into the aorta for some two or three inches. [This was supposed by the reporter to be the cause of death.] The glands of Peyer were healthy. Some evidences of chronic inflammation of the colon were observed, but nothing very marked.—Acting Assistant Surgeon J. Howard Pugh.

CASE 119.—Private John Schroeder, company C, 2d Maryland volunteers; admitted October 15, 1864. Chronic diarrhœa. [The records of the depot hospital of the 9th Corps show that this man was treated for chronic diarrhœa in that hospital from September 30th to October 13th.] Died, October 30th. *Autopsy* twelve hours after death: The whole surface of the left lung was bound by old adhesions to the costal pleura. The descending colon presented numerous ulcers, some of them penetrating to the peritoneal coat.—Acting Assistant Surgeon J. Howard Pugh.

CASE 120.—Private Edward Anderson, company D, 2d New Jersey heavy artillery; admitted November 2, 1864. Diarrhœa. [The records of the 2d Division hospital, Alexandria, Virginia, show that this man was treated in that hospital for chronic diarrhœa from October 21st to November 1st, when he was transferred to Judiciary Square hospital, Washington, D. C., whence, next day, he was sent to Beverly.] Died, February 17, 1865. *Autopsy* thirty hours after death: The brain was not examined. The thoracic cavity contained about three pints of fluid. The lungs and heart were healthy, but the latter was remarkably small. The pericardium contained about two ounces of fluid. The liver, spleen, pancreas, kidneys, and bladder were normal. The ascending colon presented evidences of chronic inflammation; in the transverse colon there were several elliptical ulcers varying from one to two inches in length; the descending colon presented a healthy appearance. The mesenteric glands were considerably tumefied.—Acting Assistant Surgeon Franklin Gauntt.

The next three cases are from the case-book of the SOUTH STREET HOSPITAL, Philadelphia, Pennsylvania. At the date of the first case Acting Assistant Surgeon Joseph Hopkinson was in charge, at the date of the two others Surgeon Edward Shippen, U. S. V.

CASE 121.—Private John Bingal, company I, 100th New York volunteers; admitted from Harrison's Landing, Virginia, August 7, 1862. Dysentery. In this case the discharges from the bowels, which at first were very frequent, were checked by the use of acetate of lead and opium. The patient, however, was very much reduced, and a fatal relapse, with copious bloody discharges, took place August 31st. He died September 2d. *Autopsy:* The ileum in the vicinity of the ileocæcal valve was highly congested, and its mucous membrane in many places appeared to be denuded of epithelium. There was no ulceration or enlargement of Peyer's glands. The mucous membrane of the colon was thickened and congested. The mesenteric glands were enlarged and contained a firm, cheesy deposit. The gall-bladder was much distended with bile.

CASE 122.—Private Theodore Porter, company F, 67th Pennsylvania volunteers; age 47; admitted October 12, 1863. Chronic diarrhœa. This man had been a prisoner of war at Richmond, Virginia, for six months, and had suffered from chronic diarrhœa for the last four months. [On his release he was sent to Camp Parole, near Annapolis, Maryland, where the records show that he was treated for diarrhœa from July 26th to August 21st, and again from September 1st to September 5th, when he was transferred to the 1st Division of the Annapolis general hospital. The records of that hospital show that he was treated there for chronic diarrhœa until October 11th, when he was transferred to this hospital.] He was now very much emaciated. Treatment: Quinine, iron, stimulants, and a nourishing diet. October 14th, as the discharges continued to be very profuse, pills of acetate of lead and opium were ordered. October 16th, pills of calomel, ipecacuanha, and opium were substituted for the lead and opium pills. Laudanum enemata were also administered. The patient, however, continued to sink. October 23d, vomiting set in, and he died October 25th. *Autopsy* the same day: The descending colon and rectum were ulcerated, some of the ulcers being almost an inch in diameter. There was also great congestion of the cæcum. The other viscera were normal so far as examined.—Acting Assistant Surgeon Benjamin F. Butcher.

CASE 123.—Private John Leopold, company B, 74th Pennsylvania volunteers; age 67; admitted October 12, 1863. Chronic diarrhœa. This man had been a prisoner in Richmond, Virginia, for over five months. [When released he was admitted, October 2d, to the 1st Division hospital, Annapolis, Maryland, whence he was sent north October 11th.] When received into this hospital he stated that he had been suffering from chronic diarrhœa for over three months. Pills of acetate of lead and opium were ordered, together with milk-punch and beef-tea. October 14th, aromatic sulphuric acid and laudanum were substituted for the lead and opium, and laudanum enemata were ordered. Subsequently nitrate of silver, belladonna and calomel, ipecacuanha and opium, were tried without benefit. October 22d, the patient, who was now very weak, complained of slight pain in the chest. He coughed a great deal. A cough mixture was prescribed, and a mustard plaster applied to the chest. He died October 26th. *Autopsy:* The left lung was very much congested and the bronchial tubes contained a large amount of pus. The descending colon and the rectum were extensively ulcerated.—Acting Assistant Surgeon Benjamin F. Butcher.

The next fifty-eight cases are from the case-book of the SATTERLEE HOSPITAL, West Philadelphia, Pennsylvania, Surgeon Isaac I. Hayes, U. S. V., in charge. In fifty-one of these cases the autopsies were made by Dr. Joseph Leidy, Professor of Anatomy in the University of Pennsylvania. At the time of the organization of this hospital a number of the leading teachers and medical practitioners of Philadelphia volunteered their services

as ward physicians, and accordingly received contracts as acting assistant surgeons. To Dr. Leidy was assigned the task of conducting the autopsies, and a report of the results was forwarded by him, at the time, to the Surgeon General. This report was accompanied by a number of valuable pathological specimens, which have been preserved in the Army Medical Museum. Those of Dr. Leidy's autopsies which are here presented were made between the 5th of August, 1862, and the 18th of February, 1863. The great majority of the patients were sent to Satterlee hospital from the Army of the Potomac at Harrison's Landing, and had contracted their disease in the swamps of the Chickahominy and before Yorktown during the ill-fated Peninsular campaign. It is greatly to be regretted that in most of them no record was made of the symptoms during life. Probably if this had been done several of the cases here reported would have been reserved for the chapter on fever. As it is, all of Dr. Leidy's cases in which the diagnosis of diarrhœa or dysentery was recorded on the hospital register are here presented, with the exception of a few in which the lesions of enteric fever were unmistakable, and a few others in which illustrations have been prepared from the specimens, and which will be reserved for Section IV.

CASE 124.—Private William Vancleve, company C, 8th New Jersey volunteers; age 45; admitted from Harrison's Landing, Virginia, July 30, 1862. Chronic dysentery. Died, August 4th. *Autopsy* next day: The organs of the chest were normal, except a few small spots of atheroma in the mitral valve and the coats of the aorta. The organs of the abdomen appeared normal, except the intestines. The mucous membrane of the ileum was inflamed in patches from a few inches to a foot in length, with the intervening parts apparently healthy. The mucous membrane of the colon was also inflamed, but not ulcerated, the inflammation being most aggravated in the cæcum, descending colon, and rectum.—Acting Assistant Surgeon Joseph Leidy.

CASE 125.—Private Charles Butler, company A, 95th Pennsylvania volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. Died August 11th. *Autopsy* next day: Age about 40; body much emaciated. Pneumonia of the right lung, except at its apex, all other portions being in the stage of transition to gray hepatization. Pleurisy, with thin pseudomembrane in small patches on the surface of the lung, the lobes of which were likewise agglutinated, but were not attached to the costal or phrenic pleura. Left lung and heart natural. Fatty degeneration of the cortical substance of the kidneys, with a urinary cyst, about an inch in diameter, in the upper part of the left one. The remaining organs of the abdomen appeared normal.—Acting Assistant Surgeon Joseph Leidy.

CASE 126.—Private F. Gillen, company D, 32d New York volunteers; age 25; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. Died August 13th. *Autopsy* next day: Body considerably emaciated; organs of chest healthy. Stomach, liver, spleen, pancreas, and kidneys natural. Mucous membrane of the small intestine red or inflamed throughout, but in the greatest degree in the ileum; solitary glands of the latter quite prominent. Agminated and solitary glands of both small and large intestine apparently healthy, but rendered unusually conspicuous by the deposit of black pigment; this appeared as fine molecules in the glands of the small intestine; in those of the large intestine it appeared in the same manner, but was mingled with nuclear bodies filled with the pigment, the nuclear bodies apparently being those usually found in the solitary glands, but altered in condition. The mucous membrane in both extremities of the colon was inflamed; in the intermediate portion of the latter it presented small patches, and was generally grayish white, mingled with slate color, and tinged yellowish from bile. The glands of the mesentery were somewhat enlarged; one of them, the size of a shell-bark, was filled with softened tubercular matter.—Acting Assistant Surgeon Joseph Leidy.

CASE 127.—Private James R. Eastman, company I, 5th Wisconsin volunteers; age 56; admitted from Harrison's Landing, Virginia, August 10, 1862. Diarrhœa. Died, August 13th. *Autopsy* next day: Vigorous appearance, and only slight emaciation. The thoracic and abdominal viscera exhibited no perceptible lesions.—Acting Assistant Surgeon Joseph Leidy.

CASE 128.—Private Alpheus Bass, company C, 32d New York volunteers; age 26; admitted from Harrison's Landing, Virginia, August 10, 1862. Diarrhœa. Died, August 14th. *Autopsy* same day: The body was much emaciated. The organs of the thorax appeared healthy. The mucous membrane of the small intestine throughout was of a pinkish cream color, and more or less tinged with bile. The agminated glands were marked with dots of black pigment, but otherwise appeared healthy. The solitary glands were imperceptible by the ordinary mode of examination. The mucous membrane of the large intestine was moderately inflamed, and the solitary glands rendered conspicuous from the deposit of black pigment. The other abdominal organs appeared to be healthy.—Acting Assistant Surgeon Joseph Leidy.

CASE 129.—Corporal Major I. Sanborn, company G, 5th Wisconsin volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Died, August 15th, apparently of debility. *Autopsy* next day: The body appeared about 45 years of age, large, and of vigorous frame, but much emaciated. No anatomical lesion was discoverable in any of the thoracic or abdominal viscera.—Acting Assistant Surgeon Joseph Leidy.

CASE 130.—Private Alonzo Hinckley, company D, 7th Maine volunteers; age 25; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. Died, August 17th. *Autopsy* next day: Body very much emaciated. The heart and lungs were healthy, except that the left lung presented old pleuritic adhesions to the costal pleura. The liver appeared healthy. Such also was the case with the spleen, except that its convex surface presented old inflammatory adhesions. The mucous membrane of the ileum and colon was inflamed; the agminated and solitary glands all contained black pigment; there were no ulcerations.—Acting Assistant Surgeon Joseph Leidy.

CASE 131.—Private William H. Champlain, company H, 17th New York volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Diarrhœa and rheumatism. Died, August 17th. *Autopsy:* The body was well made, vigorous in appearance, not wasted, and appeared to be about 25 years of age. The heart and lungs were sound, except that the latter presented old pleuritic adhesions to the costal pleura. The liver presented the light-brown mottled appearance which I usually designate as "rat liver." The spleen was healthy, but exhibited a large number of Malpighian corpuscles. The mesenteric glands were much enlarged and of a pale roseate hue. The mucous membrane of the ileum was of a pink-rose color; its solitary glands were quite prominent and opaque white; the agminated glands were thickened and opaque white. The mucous membrane of the colon was inflamed, especially at the two extremities, and the solitary glands were large, prominent, and opaque white. Microscopically examined, the Malpighian corpuscles of the spleen, the solitary glands of the ileum and colon, and the agminated glands, together with the mesenteric glands, all appeared to contain the same kind of nuclear bodies, but these were not perceptibly different from those existing in the same positions under ordinary circumstances.—Acting Assistant Surgeon Joseph Leidy.

CASE 132.—Private William F. Royal, company H, 6th Maine volunteers; age 24; admitted from Harrison's Landing, Virginia, August 10, 1862. Diarrhœa and debility—supposed to be convalescent from typhoid fever. Died suddenly, August 19th. *Autopsy* next day: The body, apparently aged about 22 years, was very much emaciated, and the skin of the trunk was somewhat diffusely ecchymosed; there were also bed-sores on the hips. The lungs and heart were natural. There was about a gill of liquid in the pericardium. The liver and spleen appeared natural. The stomach was contracted and empty, and some of the rugæ along its greater curvature were highly injected. The mucous membrane of the ileum was inflamed in patches from a few inches to a foot or more in length; the agminated glands were thickened, and either white or reddened from inflammation, but none were ulcerated, nor did they appear to have been so; the solitary glands were inconspicuous. The mucous membrane of the colon was slate colored, with small red inflamed patches; it also presented a number of large ulcers, extending to the muscular coat; one of the ulcers, within the cæcum, had perforated; the perforation appears to have occurred just previous to death, as it had not given rise to peritonitis, except some injection of the peritoneum in the immediate vicinity of the aperture, in the right iliac fossa. Kidneys natural.—Acting Assistant Surgeon Joseph Leidy. [No. 43, Medical Section, Army Medical Museum, is from this case. The specimen consists of a portion of the cæcum, which presents a number of large, irregular, superficial diphtheritic ulcers, one of which has perforated. The mucous membrane hangs in shreds from the edges of the ulcer.]

CASE 133.—Private Charles Caloney, company B, 34th New York volunteers; admitted July 7, 1862. Debility and diabetes. Died, August 21st. *Autopsy* next day: The lungs were healthy, except a few old adhesions attaching them to the costal pleura. The heart also appeared healthy, except that there existed an old pseudomembrane, about the size of a dime, adherent to the left ventricle near its apex. The pseudomembrane was fringed, the processes being about one-third of an inch in length. The liver appeared of the usual size and consistence, but was livid purple above and slate colored below. The spleen appeared healthy. The stomach was moderately distended with air and liquid food; its mucous membrane was red in small spots, and there was a patch of inflammation about two inches square near the pylorus. The mucous membrane of the ileum was inflamed in patches; its solitary glands were prominent, and the agminated glands were red and inflamed, or were thickened and opaque white. The colon was distended with air; its mucous membrane presented small patches more than usually injected, and its solitary glands were inconspicuous. The kidneys were below the average size, and their cortical substance was much paler than usual, the tint being pinkish cream colored. The microscope presented the usual condition of the granular cells, (*i. e.*, there was no obvious fatty degeneration.)—Acting Assistant Surgeon Joseph Leidy.

CASE 134.—Private Charles Cramer, company K, 104th Pennsylvania volunteers; age 30; admitted from Harrison's Landing, Virginia, August 9, 1862. Chronic diarrhœa. Died, August 22d. *Autopsy* next day: The body appeared to be about 45 years of age, and was exceedingly emaciated. Considerable ecchymosis was diffused over an extent of about six inches in the neighborhood of the scrobiculus cordis. There was a suppurating sinus about four inches long between the scalp, temporal fascia, and frontal bone, extending from the front of the ear above to the right side of the forehead. The bone was not necrosed, and the sore appeared to be the result of a contusion. The organs of the chest were perfectly sound. The liver healthy. The spleen unusually firm, and Indian-red on section. Stomach in pyloric half contracted to an inch in diameter, and in corresponding degree in cardiac half. Small intestine moderately contracted. Ascending and descending colon narrowly contracted; transverse colon distended with air. Inflammation of the ileum and colon, and a number of blackish ulcers in descending portion of latter; no disease of the intestinal glands, except that they contained a deposit of black pigment. Kidneys sound.—Acting Assistant Surgeon Joseph Leidy. [Nos. 63 and 64, Medical Section, Army Medical Museum, are from this case. No. 63 is the stomach, which is contracted to a tube about half an inch in diameter in its pyloric half, and about two inches in diameter at the largest part of the greater curvature. No. 64 is a portion of the descending colon, which is considerably thickened, and presents numerous follicular ulcers, varying in size from mere points to three lines in diameter. A lithograph of this specimen was published in the Catalogue of the Medical Section of the Army Medical Museum, facing page 72.]

CASE 135.—Private Edward Reagan, company F, 9th Massachusetts volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Gunshot flesh wound and diarrhœa. Died, August 22d. *Autopsy* next day: Body apparently aged about 20 years; moderately emaciated. There was a gunshot wound penetrating the outer side of the right thigh which extended beneath the rectus muscle, but did not involve the bone. The right lung was healthy; the left presented old adhesions

to the costal pleura, and was in a recent stage of pneumonic congestion. The heart, stomach, and liver appeared natural. The spleen, externally, presented an unnaturally blue appearance, and was almost black on section, but otherwise appeared normal. The mucous membrane of the ileum was inflamed in patches, and the solitary and agminated glands contained a deposit of black pigment. The ascending and descending colon presented inflammation of the mucous membrane, and the solitary glands contained black pigment. The transverse colon was free from inflammation, but presented a single ulcer about the size of a dime, extending through the mucous and submucous coats. The peritoneum, corresponding to the position of the ulcer, was injected.—Acting Assistant Surgeon Joseph Leidy.

CASE 136.—Private Peter Mosier, company K, 6th Vermont volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa and recent pneumonia. Died, August 23d. *Autopsy* next day: Old adhesions of the pleura at apex of right lung and some recent ones at its base. Lower and posterior part of same lung deeply congested, in the stage of red hepatization. Left lung normal. Inflammation of the mucous membrane of the colon.—Acting Assistant Surgeon Lenox Hodge.

CASE 137.—Private Franklin Lammundy, company A, 95th New York volunteers; admitted from Harrison's Landing, Virginia, August 19, 1862. Phthisis. Died, August 25th. *Autopsy* next day: Body stout; age about 35 years. There were old adhesions of both lungs to the costal pleuræ. The pericardium was distended with a serous liquid, containing a few thin fibrinous shreds. Attached to the surface of the right auricle were a few small shreds of pseudomembranous matter, and the reflected pericardium was somewhat injected. The left lung contained much mucus and blood. The lower lobe of the right lung, at its inferior part, was in the condition of gray hepatization. The liver appeared normal, but presented a patch of adhesion about the size of the palm of the hand on the convex surface of the right lobe; though not recent, the adhesion, from its being somewhat discolored by blood on the hepatic surface, was probably not an old one. The stomach and spleen presented nothing abnormal. There was no inflammation in the small intestine, but there were small injected patches of the mucous membrane of the ascending colon. All the solitary and agminated glands were dotted with black matter. The blood in all the organs was very liquid, and poured forth freely on making incisions. The kidneys appeared sound, except that the right one presented an ecchymosis on the outer border the third of an inch in diameter and extending inwardly.—Acting Assistant Surgeon Joseph Leidy.

CASE 138.—Private James T. Wood, company H, 4th Michigan volunteers; age 26 years; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa and debility of three months' standing. Died August 23th. *Autopsy* next day: Body emaciated; the front of the trunk and thighs exhibiting a diffused ecchymosed condition. Organs of the chest healthy; the lower lobe of the left lung presented an old stellate cicatrix on its convex surface about two inches in diameter. Spleen small, Indian-red on section. Rat liver. Stomach sound. Mucous membrane of the ileum inflamed in small patches; solitary and agminated glands marked by black pigment. Colon contracted, its mucous membrane presenting small inflamed patches, blackened solitary glands, patches of desquamating epithelium, and in the descending portion eight small ulcers.—Acting Assistant Surgeon Joseph Leidy.

CASE 139.—Private G. Miller, company D. 33d New York volunteers: admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. Died, August 27th, at 12 M. *Autopsy* ten hours after death: The body, apparently aged about 21 years, was much emaciated, and the skin of the trunk presented diffused ecchymoses. Heart with an ecchymosed spot at base of right ventricle in front, but otherwise natural; the left side was empty, the right contained only some liquid blood. The lungs, of a roseate hue generally, contained a number of isolated nodular masses of effused blood about the size of shell-barks, some of which had a white central nucleus; besides these, the lungs presented a somewhat congested character at their lower part. The liver, rather small, presented the minutely mottled appearance of red and brown, which I denominate "rat liver;" the tissue of the organ exhibited some fatty degeneration. The gall-bladder was unusually large, extending two and a half inches in advance of the anterior edge of the liver. Spleen small, red on section, but apparently healthy. Stomach distended with air and liquid; softening of the mucous membrane, submucous coat, and muscular coat in the greater part of the left half, so that the wall was reduced to the utmost tenuity, and ruptured on the feeblest traction. The ileum presented the anatomical peculiarity of numerous valvulæ conniventes extending to the ileocolic valve: inflammation of the mucous membrane of the ileum continuously throughout, but with patches of greater intensity; solitary glands few, containing black matter; agminated glands generally healthy, except that some were reddened with inflammation—none contained black matter. Mucous membrane of the colon inflamed throughout, with many small ulcers and patches of desquamating epithelium in the lower part, solitary glands blackened.—Acting Assistant Surgeon Joseph Leidy.

CASE 140.—Private William Burrows, company E, 5th Wisconsin volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Diarrhœa. This man was attacked with fever and diarrhœa last April at Yorktown, but continued to do duty until he arrived with the army in the swamps of the Chickahominy, when he entered the regimental hospital, and has been sick ever since. At the date of admission he was much emaciated, but complained of no pain or uneasiness. The stools were thin, watery, and yellow, but contained no blood. There was no fever at any time. The tongue was glazed, and studded with dirty white patches; pulse 80; the skin of the body and face of a dirty dark appearance. At first tannin, chalk-mixture, and other astringents were administered, but without benefit; then equal parts of laudanum and tincture of ergot were substituted; dose, ten drops after each passage. Quinine and beef-tea were also administered. Under this treatment the patient improved for a few days, and then relapsed. Pills containing one grain of opium to two of acetate of lead were next directed to be taken every four hours, but did not seem to agree with the patient so well as the laudanum and ergot, which was renewed August 23d. At this date the patient was weak, and emaciation was progressing rapidly, but his appetite was still good. August 25th, the diarrhœa was reduced to three discharges daily; pulse 88. All medicine was discontinued, and beef-tea and brandy ordered to be freely administered. August 27th, pulse 93; tongue glazed, but no fever; the diarrhœa has quite

ceased, and the stools appear consistent, but the patient is dull and disposed to sleep; the pupils contracted, the cornea hazy. Died, August 31st.—Acting Assistant Surgeon Wm. S. Halsey. *Autopsy* next day: Body apparently about 23 years of age, much emaciated; skin of the trunk considerably ecchymosed, especially about the epigastric region. Right lung with a few nodular masses of condensed tissue about the size of a hickory-nut; these masses presented the appearance of the red hepatization of pneumonia; the remainder of the pulmonary tissue was healthy. Heart small, without fat; the right side containing a yellow fibrinous clot. Stomach moderately contracted; its mucous membrane grayish, with one or two small red inflamed patches. Spleen with old adhesions on the convex surface, otherwise as usual. Liver with old adhesions on the convex surface of the right lobe, cicatrix-like, or stellate in appearance. (Were these old adhesions of the spleen and liver due to inflammation consequent upon a strain, of which the patient complained some months previous to his entering the hospital?) The surface of the liver was brown above, slate-colored below; the tissue was healthy in aspect. Inflammation of the mucous membrane of the ileum, with patches of same of greater intensity; agminated glands with a large quantity of black pigment deposited in the follicles; solitary glands inconspicuous. Inflammation of the mucous membrane of the colon, with patches of greater intensity, accompanied by thickening and desquamation of the epithelium in the descending portion; there were also a few ulcers in the latter, several of them apparently cicatrizing.—Acting Assistant Surgeon Joseph Leidy.

CASE 141.—Corporal Paul Grauvet, company D, 1st New Jersey volunteers; age 24; admitted from Harrison's Landing, Virginia, August 9, 1862. Diarrhœa. Died, August 31st. *Autopsy* next day: Body emaciated, and in an unusually advanced condition of decomposition. Organs of the chest sound. Recent peritonitis; all the viscera agglutinated with pseudomembrane, and the intervals occupied with an abundance of sero-purulent liquid. Liver, spleen, and stomach healthy. Inflammation of the mucous membrane of the ileum and colon; thickening of the upper agminated glands and ulceration of the lower ones; no less than three, near the ileo-colic valve, presented perforations. There were also a number of ulcers in the colon, and a large one was very near the condition of perforation; the solitary glands were thickened, and contained black pigment.—Acting Assistant Surgeon Joseph Leidy. [Nos. 232 and 233, Medical Section, Army Medical Museum, are from this case. No. 232 is a portion of the ileum presenting three ulcers, the largest of which is about two-thirds of an inch in length, and is apparently the result of typhoid destruction of a Peyer's patch. From the appearance of the edges of this ulcer, it would seem that the healing process had commenced. The other ulcers are much smaller, but present similar characteristics. No. 233 is a portion of the colon, which presents a number of oval ulcers and one large irregular one, all penetrating to the muscular coat. It seems probable from the specimens that in this case dysentery had supervened on typhoid fever.]

CASE 142.—Private George W. Beckwith, company E, 16th New York volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. Died, September 1st. *Autopsy* next day: Body, apparently aged about 20 years, emaciated; the skin of the trunk in an ecchymosed condition. Apex of the right lung with old pleuritic adhesions and deposits of tubercular matter; apex of left with tubercular deposit about the size of a walnut, including several small abscesses; remainder of the lungs healthy. Heart without fat, contracted, the right side containing a white fibrinous clot. Liver and spleen normal. Stomach with diffused inflammation of the mucous membrane. Intense inflammation of the mucous membrane of the ileum; black deposit in the agminated and solitary glands. Inflammation accompanied with thickening of the mucous membrane of the ileo-colic valve, cæcum, vermiform appendix, part of ascending colon, descending colon, and rectum; black deposit in all the solitary glands; a small patch of inflammation and two ulcers in the transverse colon. Kidneys normal, except that they each presented a slate-colored patch, which extended into the tissue of the organs the depth of two lines.—Acting Assistant Surgeon Joseph Leidy.

CASE 143.—Sergeant Ransom Bush, company K, 4th Michigan volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. Died, September 4th, at 4 A. M. *Autopsy* seven hours after death: Age about 40 years; body extremely emaciated; skin ecchymosed. Heart without fat, natural size; valves perfect; both sides contained white fibrinous clots, continuous with black ones, extending into the pulmonary artery and aorta. Two-thirds of the base of the upper lobe of right lung was in a condition of gray hepatization, and presented pleuritic adhesions on its surface; the apex of the same lobe, the middle and inferior lobes, and the left lung were healthy. Liver and spleen natural. Stomach with diffused inflammation extending from the cardiac orifice along the lesser curvature into the pylorus. Mucous membrane of the ileum with small patches of moderate inflammation; agminated glands with black deposit, but otherwise healthy; solitary glands enlarged in the inflamed patches, but elsewhere healthy. The ileo-colic valve, cæcum, and portion of the ascending colon, a small patch in the upper part of the descending colon, the sigmoid flexure and the rectum were intensely inflamed, very much thickened, and covered with small patches of pseudomembrane and desquamated epithelium; intervening spaces of the colon healthy.—Acting Assistant Surgeon Joseph Leidy.

CASE 144.—Private Ezekiel Van Brocklin, company A, 5th Wisconsin volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa and scurvy. Died, September 4th. *Autopsy* next day: Age about 25 years; body slightly emaciated. Heart of normal appearance, containing white fibrinous clots in both sides. The lungs presented the remains of pneumonic induration, and also exhibited a few old pleuritic adhesions. The liver presented old adhesions on the convex surface of the right lobe. Spleen normal. Stomach moderately distended with air, bile, and mucus—acute gastritis—a large intensely inflamed patch at lower part about the middle, and a less degree of inflammation at the two extremities. Some of the valvulæ conniventes of the duodenum inflamed; inflammation also of the mucous membrane of the ileum, with two patches of greater intensity. Slight inflammation here and there of the mucous membrane of the colon, especially in the cæcum. Agminated and solitary glands blackened.—Acting Assistant Surgeon Joseph Leidy.

CASE 145.—Private Patrick Purcell, company E, 49th New York volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Debility accompanied with diarrhœa. Died, September 8th, at 11 A. M. *Autopsy* next day: Apparent age about 45 years; extreme emaciation. Both lungs with old pleuritic adhesions, but the organs themselves healthy. Heart

flabby; right ventricle contained a small white clot. Spleen lake-red on section. Liver somewhat enlarged and fatty. Stomach and intestines distended with air. Inflammation in patches in the ileum; its glands healthy. Inflammation of cæcum and sigmoid flexure of colon; a less degree in rectum, and a feebler degree in ascending and descending colon; there were also a number of small ulcers about the size of a pea in the sigmoid flexure and rectum; solitary glands with black deposit, but otherwise healthy. Kidneys healthy.—Acting Assistant Surgeon Joseph Leidy.

CASE 146.—Private William Roberts, company C, 33d New York volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. Died, September 13th. *Autopsy* same day: Age about 25 years; body not wasted; no ecchymosed appearance of skin. Lungs healthy. Heart with several opaque fibrinous spots on ventricles the size of a half dime; it contained only liquid blood. Liver dull-brown, apparently healthy; gall-bladder small, and contained about a table-spoonful of mucous, viscid bile. Spleen natural. Kidneys large but natural. Stomach moderately dilated, nearly empty, with general moderate diffused inflammation of mucous membrane; the redness in closely arranged spots the size of mustard-seed. Inflammation in patches in ileum; one patch, pretty high up, about three inches long, gangrenous, extending to peritoneum; intense inflammation of ileocolic valve; the agminated glands healthy, except a few reddened with inflammation; solitary glands healthy. Moderate diffused inflammation throughout colon, increased in degree in the cæcum and rectum; no ulcerations, and solitary glands healthy.—Acting Assistant Surgeon Joseph Leidy.

CASE 147.—Private B. B. True, company B, 3d Vermont volunteers; admitted August 9, 1862. Anasarca and chronic diarrhœa. [The regimental records of the 3d Vermont volunteers show that this man was excused from drill on account of fever June 3d; next day he was admitted to the regimental hospital, and the case threatening to be serious, he was immediately transferred to the division hospital, where he recovered, partially at least, and was returned to his regiment, though at what time is not known, as the records of the division hospital are not on file. He appears again on the regimental records as excused from drill July 6th, and admitted to the regimental hospital the same day, the diagnosis recorded being scurvy. He is reported sent to general hospital July 25th, probably the division hospital, as the register of the Satterlee hospital reports him admitted from Harrison's Landing, Virginia, at the date given above.] Died, September 14th, at 5 A. M. *Autopsy* next day: Aged about 30 years; body exceedingly emaciated. Lungs as bright in color as those of a new-born child; a few old adhesions, but otherwise healthy. Heart natural, contained a white clot in the left auricle, and another occupied the pulmonary artery. Liver dull purple. Spleen lake-red on section, and natural in size. Stomach with general diffused inflammation, the injection appearing in small but closely associated maculæ. Kidneys natural. Patches of inflammation in the ileum; agminated glands slightly thickened, and contained black matter. Intense inflammation of the ileo-colic valve, the cæcum, the lower extremity of the colon, and the rectum; the latter presented, on the summits of its rugæ, white patches of desquamating epithelium; solitary glands of colon blackened.—Acting Assistant Surgeon Joseph Leidy.

CASE 148.—Private Oliver F. Kellner, company E, 33d New York volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa and debility. Died, September 15th. *Autopsy* next day: Age about 23 years; body much emaciated; ecchymoses on chest and abdomen. Lungs and heart healthy. Liver, spleen and kidneys healthy. Stomach with inflammation of mucous membrane and softening of the cul-de-sac. Inflammation of the jejunum and ileum, increasing in intensity in descent; enlargement of solitary glands in lower part of ileum, and inflammation of agminated glands generally. Inflammation at both extremities of colon intense, with a slight degree in the intervening portion; the solitary glands of the colon enlarged and containing a black deposit, besides which there were a number of scattered black spots about the size of pepper-corns throughout the tract of the colon.—Acting Assistant Surgeon Joseph Leidy.

CASE 149.—Private Peter Dixon, company H, 17th New York volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa and debility. Died, September 17th, at 7 A. M. *Autopsy* twenty-seven hours after death: Age about 30 years; body much emaciated; skin of trunk and extremities much ecchymosed. Heart healthy, but wasted; without white clots. Lungs with a few nodular masses of congested and somewhat condensed tissue about the size of shell-barks, but otherwise healthy. Liver dull-brown above, slate-colored below, apparently healthy. Spleen, pancreas, and kidneys healthy. Right suprarenal body with brown cortical substance and grayish medulla; left one with cortical substance yellowish externally, but brown internally, and medulla grayish. Stomach with acute inflammation around cardiac orifice and in cardiac half of the organ; in less degree around the pylorus. Inflammation of the ileum extending pretty high up, with patches of greater intensity below; agminated glands slightly thickened, and all bright-red from inflammation; solitary glands all surrounded by bright-red circles. Moderate inflammation throughout tract of colon, but most marked at the extremities—in neither, however, intense; the solitary glands with a small amount of black matter; there were also a few scattered spots of black matter about the size of pepper-corns, especially in the ascending and descending colon.—Acting Assistant Surgeon Joseph Leidy.

CASE 150.—Private Eli Lombard, company K, 6th Vermont volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. Died, September 18th, at 4.30 P. M. *Autopsy* next day: Apparent age 20 years; slight emaciation; skin of trunk and thighs with purpura. Recent pleuro-pneumonia of left lung; right lung healthy. Heart somewhat flabby, with a white clot in the right ventricle. Liver apparently sound, dull-brown above, slate-colored below. Spleen natural. Stomach distended with air and a small quantity of liquid; inflammation extending some distance around the cardiac orifice, and softening of cul-de-sac. Intensely inflamed patches in the ileum, with intervening healthy surfaces; agminated glands healthy, except that they contained black pigment; solitary glands natural, except at lower end of ileum, where they were enlarged and inflamed. Intense inflammation, accompanied with desquamation of epithelium of ileo-colic valve, cæcum, and ascending colon; moderate inflammation here and there in course of descending colon and rectum; no ulcerations; solitary glands black; suprarenal bodies and pancreas healthy. Kidneys with pinkish cream-colored cortical substance, the cells of which exhibited, beneath the microscope, a much greater quantity of oil globules than usual.—Acting Assistant Surgeon Joseph Leidy.

CASE 151.—Private Carl Doerlinger, company E, 20th New York volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. Died, September 21st, at 10 A. M. *Autopsy* next day: Apparent age 32; body extremely emaciated; the skin exceedingly ecchymosed, especially over the region of the liver. Right lung with old adhesions to the costal pleura; recent congestion in both lungs, which were black on section, but everywhere pervious to air; in both there were a few calcified, dry, and chalky tubercles about the size of peas. The black bronchial glands contained calcified deposits. The heart exhibited the remains of an old pericarditis by granular roughness of the right auricle and an attachment between the front of the right ventricle and the pericardial sac. Liver dull-brown, with slate-colored patches below, and slate-colored spots on section about the size of a dime; in both lobes there were several white firm tumors the size of shell-barks; these, beneath the microscope, exhibited a fibro-plastic character. Gall-bladder distended with about five ounces of bile. The spleen, rather larger than usual, was black on section. The lymphatic glands at the head of the pancreas were enlarged and contained dry, chalky deposits; the mesenteric glands, somewhat enlarged, were inflamed, but contained no abnormal deposits. Kidneys presented nothing unusual; the suprarenal bodies were brownish on section, with a dark-brown medulla. Stomach with characters of gastritis; the inflammation occupied the middle portion and extended from the small curvature downward in front and behind; the mucous membrane also presented recent ecchymosed spots. Inflammation of the duodenum and jejunum, extending to a less degree in the commencement of the ileum, which, at lower part, appeared entirely free from it—the very reverse of what has been so repeatedly observed in our former examinations; there were fifty conspicuous agminated glands, besides a number of small ones about one line in diameter; all of them, together with the solitary glands, contained black deposits. Intense inflammation in the cæcum, and six small patches of less violent inflammation along the course of the colon, the intervening spaces being slightly inflamed or healthy; solitary glands healthy and without black deposits. Testes hard and irregular, the right one being much enlarged; both affected with sarcocele; the right one presented an accumulation of bloody pus upon the surface; on section the natural tissue appeared marbled with a homogeneous yellowish-white substance, which, beneath the microscope, exhibited the fibro-granular structure of fibro-plastic matter; it contained a number of fat granules, which probably gave rise to the yellowish color, and indicated fatty degeneration.—Acting Assistant Surgeon Joseph Leidy. [Nos. 17, 18, and 19, Medical Section, Army Medical Museum, are from this case. No. 17 is the right testicle, and No. 18 the left. Both are tubercular; in the anterior and inferior portions of the right are a number of cheesy nodules, in the inferior portion of the left two rather large ones. No. 19 is a group of bronchial glands filled with calcareous concretions.]

CASE 152.—Corporal J. L. Blake, company I, 7th Maine volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Diarrhœa. Died, September 23d, at 8 A. M., of diphtheria. *Autopsy:* Apparent age about 30 years; body good looking, vigorous, and not wasted. The fauces and pharynx to the commencement of the œsophagus, the larynx, trachea, and bronchi were inflamed and lined with pseudomembrane; the tissue of the lungs was healthy, but the bronchial tubes were filled with mucus; some blood was effused into the interlobular connective tissue; the apex of the right lung was tied by an old pleuritic adhesion. The heart was healthy. The liver, spleen, pancreas, and kidneys were healthy. The stomach exhibited evidences of gastritis, and was more or less inflamed throughout. The mucous membrane of the duodenum, jejunum, and ileum was slightly reddened and stained with bile; the large intestine was exceedingly contracted, and was nearly uniformly pink throughout.—Acting Assistant Surgeon Joseph Leidy. [No. 12, Medical Section, Army Medical Museum, is from this case. The specimen consists of the posterior portion of the tongue, with the larynx, trachea, and commencement of the bronchial tubes. The air-passages are laid open posteriorly, and are lined by a diphtheritic layer, which hangs in shreds.]

CASE 153.—Private George M. D. Dustin, company E, 2d Vermont volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa and debility. [The regimental records of the 2d Vermont volunteers report this man admitted with diarrhœa July 28th, and sent to general hospital August 6th.] Died, September 24th, at 10.30 A. M. *Autopsy:* Apparent age about 19; body much emaciated, with petechiæ on chest and abdomen. Old adhesions to right lung throughout; the left free, and both healthy. Heart natural, with a white clot in the right ventricle extending into the pulmonary artery. Liver bright reddish-brown, with the acini very distinct—rat liver. Spleen and pancreas natural. Mucous membrane of the stomach inflamed, with several patches of greater intensity, and accompanied by softening. Inflammation of the ileum, patches of greater intensity toward the middle and declining above and below; enlargement of solitary glands, which, together with the agminated glands, contained black matter. Two patches of inflammation in the ascending colon, with moderate diffused inflammation elsewhere; black solitary glands. Kidneys healthy. Suprarenal bodies, on section, purplish-brown, the cortical substance being of a slightly lighter hue.—Acting Assistant Surgeon Joseph Leidy.

CASE 154.—Private Jefferson Brown, company F, 7th Maine volunteers; admitted August 10, 1862. Chronic diarrhœa. Died, October 8th. *Autopsy:* Apparent age about 27 years; much emaciated; skin slightly ecchymosed. Organs of the chest healthy. Liver dull brownish-purple, on section brown; gall-bladder large and distended. Spleen flabby, remarkably bloodless, on section bright lake-red. Pancreas, kidneys, and suprarenal bodies natural. Continuous inflammation throughout the small intestines, commencing feebly in the duodenum and gradually increasing in intensity in the descent. The ileum was of a deep maroon color, without any destruction of epithelium; the muscular and subserous coats of the ileum were likewise considerably injected. Intense inflammation of ascending colon; transverse colon nearly free; the descending colon, sigmoid flexure, and rectum in a moderate degree inflamed, here and there ecchymoses. Agminated glands not perceptibly altered, nor did they contain the black pigment so frequently observed in other cases. Solitary glands exceedingly numerous, or unusually conspicuous from enlargement; those of the colon appeared natural, and only a few contained black matter.—Acting Assistant Surgeon Joseph Leidy. [Nos. 237 and 238, Medical Section, Army Medical Museum, are from this case. Both are portions of the ileum, the latter taken from a point nearer the ileo-cæcal valve than the former. In both the solitary glands are enlarged to the size of pin-heads and the villi somewhat hypertrophied. In No. 237 there is a small slightly thickened Peyer's patch; in No. 238 is a much larger Peyer's patch, also slightly thickened, and presenting a mammillated surface.]

CASE 155.—Private Charles H. Reed, company D, 18th New York volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. Died, October 15th. *Autopsy* same day: Apparent age about 30 years; emaciation very great. The lower lobe of the right lung and the lower part of the upper one were affected with pneumonia and slight pleuritic inflammation; the middle lobe and apex of the upper were perfectly healthy. Left lung healthy. Heart natural in size and structure; both ventricles contained large white clots extending into their arteries of exit. Liver brown, somewhat mottled with brownish-buff, but apparently healthy. Spleen small, lake-red on section. Stomach, pancreas, and kidneys sound. Moderate diffused inflammation of the ileum, a greater degree in the cæcum and ascending colon, and small moderate patches in the sigmoid flexure. Solitary glands of the ileum enlarged to the size of yellow mustard-seed and reddened with inflammation; those of the colon containing black matter; agminated glands containing black matter, but otherwise healthy.—Acting Assistant Surgeon Joseph Leidy.

CASE 156.—Private Job M. Chubbuck, company G, 49th New York volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. Died, October 14th. *Autopsy* next day: Apparent age about 30 years; body much emaciated. Organs of the chest, liver, and stomach healthy. Spleen small, lake-red on section. The small intestine persented four intussusceptions; its mucous membrane was continuously and intensely inflamed, excepting in the duodenum and commencement of the jejunum. The large intestine was extremely contracted, not being more than one inch in diameter throughout, except at the cæcum and four inches of the ascending portion, which were about two and a half inches in diameter; it contained considerable hardened clay-colored fæces. The mucous membrane was inflamed throughout, but most intensely in the ascending colon. Solitary and agminated glands contained black matter.—Acting Assistant Surgeon Joseph Leidy.

CASE 157.—Private Daniel Leduc, company A, 5th Vermont volunteers; admitted August 10, 1862. Diarrhœa. Died, October 23d, at 10.30 A. M. *Autopsy* five and a half hours after death: Age apparently about 25 years; body exceedingly emaciated. Heart natural. Right lung with old adhesions at the apex, the posterior part infiltrated with blood and serum and devoid of air, the anterior part healthy; upper lobe of left lung with old pleuritic adhesions, the back part of the lower lobe infiltrated as in the right lung. Extreme contraction of the intestines; a single intussusception about the commencement of the ileum; inflammation from the stomach to the anus; the solitary glands of the small intestine were quite conspicuous, and appeared as numerous dark-red spots as large as pin-heads. Mesenteric glands enlarged, many of them containing creamy-white matter and yellow pus. Spleen quite small, lake-red on section. Liver brown and apparently healthy; gall-bladder full of bile. Pancreas and suprarenal bodies normal. Kidneys large, and pale on section, with pale cortical substance.—Acting Assistant Surgeon Joseph Leidy.

CASE 158.—Corporal Thomas Malia, company B, 31st New York volunteers; admitted August 10, 1862. Chronic diarrhœa. [The records of the regimental hospital of the 31st New York volunteers show that this man was admitted to that hospital for diarrhœa July 31st; August 5th, the diagnosis remittent fever and incipient scurvy is recorded; August 7th, fever. There is no later entry on the regimental records.] Died, October 24th, at 9 P. M. *Autopsy* next day: Apparent age about 25 years; very much emaciated, and skin of trunk and thighs ecchymosed, as in Chickahominy diarrhœa cases. Right lung with adhesions of the upper lobe, the apex tuberculous, and with a cavity about the size of a walnut; the remainder of the right and the left lung healthy. Effusion of serum into the pericardium. Heart normal in size and external appearance; right ventricle with a white coagulum about as large as a filbert; left ventricle with the walls dark reddish-brown, and the mitral valve thickened one line at the free border. Stomach with some inflammation at the pyloric end. Liver dull purplish-brown; gall-bladder large, and distended with bile. Spleen very small, pale and flabby; on section pale Indian-red. Kidneys dark-red on section, the medullary portion pale. Bladder distended with a quart of urine, and extending four inches above the pubis. No stricture of the urethra. The ileum exhibited traces of patches of inflammation, and the cæcum and ascending colon exhibited traces of inflammation, as if the case had been one of Chickahominy diarrhœa. The capillary vessels were not congested, but the large vessels were engorged; there were a few ecchymosed spots in the colon about the size of a dime. Solitary glands of the ileum healthy, those of the colon containing black matter; the agminated glands were remarkably few, and also contained the black deposit.—Acting Assistant Surgeon Joseph Leidy.

CASE 159.—Private Valentine McSherry, company C, 3d Vermont volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. [The records of the regimental hospital of the 3d Vermont volunteers, Harrison's Landing, Virginia, show that this man was admitted for diarrhœa July 29th, and sent to general hospital August 7th. A note on the register says: Excused from drill July 24th.] Died, November 3d. Note of Dr. Leidy: Apparently of debility, while considered convalescent from Chickahominy diarrhœa. *Autopsy* same day: Apparent age about 22; extreme emaciation. Heart and lungs healthy, the former with a small white clot in the right ventricle. Small intestines for the most part quite healthy in appearance; the ileum presenting traces of the usual inflammatory patches so common in the Chickahominy diarrhœa cases; the solitary glands white, and the agminated glands in the same condition, except the lower ones, which still contained black pigmentary matter in globular molecules up to particles the size of blood corpuscles. The cæcum was inflamed, and contained a quantity of fragments of chicken bones from food; there was also more or less inflammation irregularly diffused throughout the colon, increasing in intensity in the rectum. Spleen, liver, and pancreas apparently healthy. The kidneys likewise appeared healthy, but both pelves contained a small quantity of calculous matter. The mesenteric glands were somewhat enlarged, and white in color; the enlargement being due to a great increase in the corpuscular elements. The blood presented nothing peculiar, both kinds of corpuscles appearing in the usual quantity.—Acting Assistant Surgeon Joseph Leidy.

CASE 160.—Private Oliver P. Smith, company K, 102d New York volunteers; admitted September 26, 1862. Diarrhœa. Died, November 14th, at 7.30 A. M. *Autopsy* the same day: Apparent age about 20 years; body exceedingly emaciated; skin of trunk ecchymosed. The patient was apparently convalescent from Chickahominy diarrhœa. Right lung healthy; left healthy, except the lower half of the upper lobe, which appeared to have been the seat of recent and active inflammation, as it

contained a multitude of purulent foci, and was adherent by plastic matter to the pleura costalis. The heart was excessively emaciated, but otherwise healthy; it contained no clots, but yellow clots occupied the arch of the aorta and the pulmonary arteries. Liver dull-brown, hard, and small; gall-bladder full of bile. Spleen round, but containing little blood. Stomach and intestines contracted; the small intestine with traces of former inflammation. The colon was inflamed throughout, and patches of pseudomembrane were adherent to its mucous surface; these were composed of fibrinous matter mingled with corpuscles resembling those of pus and epithelial cells. Solitary and agminated glands contained black deposit. Blood thin, with diminished number of corpuscles, but white and red ones in the ordinary proportion. The ecchymosed spots, examined with the microscope, appeared to be a staining of the dermis with the coloring matter of the blood corpuscles.—Acting Assistant Surgeon Joseph Leidy.

CASE 161.—Private Tennent R. Spencer, company D, 4th Michigan volunteers; age 35 years; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa. The patient was much emaciated, and had frequent loose stools. Treatment: Astringent enemata, astringents and opium internally, milk-punch freely, milk diet, &c. He gradually failed, and died November 25th, at 6.30 A. M. *Autopsy* same day: Body extremely emaciated; left lower extremity œdematous. Slight adhesions of the apex of the right lung; both lungs otherwise healthy. Heart healthy. Liver soft and fatty. Stomach with subacute inflammation of the mucous membrane. A moderate degree of inflammation of the ileum, with traces remaining of more acute patches. Inflammation throughout the colon, with a few superficial ulcers and small irregular patches of pseudo-membranous matter adhering. Spleen bloodless. Mesenteric glands slightly enlarged. Pancreas, kidneys, and suprarenal bodies healthy.—Acting Assistant Surgeon Joseph Leidy.

CASE 162.—Private Jacob Walsh, company K, 2d United States infantry; age 21; admitted August 10, 1862. Typhoid fever. Died suddenly, December 10th, at 5 P. M., of pneumonia. *Autopsy* next day: Body inclined to be fat, with no signs of emaciation. All the vessels of the head, chest, and upper extremities were engorged with liquid blood, which flowed freely on incision through the scalp. Brain healthy. The heart somewhat enlarged, filled with blood and large white clots. Pericardium contained about a teacupful of serum. Both lungs in a state of pneumonic congestion, leaving very little of the tissue pervious to air; an advanced stage of pleurisy also, with adhesions on both sides to the costal pleuræ. Liver large, pale, but not fatty. Stomach healthy. Spleen pale. Kidneys healthy. Suprarenal bodies discolored and dull-brown throughout. Pancreas healthy. The intestines exhibited traces of inflammation in patches, such as accompanies the chronic diarrhœa of Chickahominy cases. Solitary glands of small intestine enlarged; agminated glands with small patches of black deposit. Solitary glands of large intestine intensely black.—Acting Assistant Surgeon Joseph Leidy.

CASE 163.—Private Thomas Kelley, company A, 124th New York volunteers; admitted December 12, 1862. Diarrhœa. The patient was not confined to bed. On the 18th he was moving about, and in the evening ate his supper with other patients. The same night he was slightly delirious. Died, December 19th, at 11 P. M. *Autopsy* next day: Body not emaciated; apparent age about 28 years. Upon the body, especially the thighs, there were a number of irregular spots of purpura from the size of a flea-bite to that of a dime. The blood was very liquid, and poured forth from incisions of the skin and all the internal organs. The brain was examined, but exhibited no unhealthy marks. Pleuritic adhesions throughout, on both sides, of not very old date. Left lung crepitant, but engorged with a bloody liquid. The upper lobe of the right lung hepatized; the lower lobes congested. There was slight atheroma throughout the course of the aorta. Liver soft, Indian-red in color, and large. Spleen large, flabby, and on section dark Indian-red; its convex surface exhibited the remains of a former inflammation. Stomach, pancreas, kidneys, and suprarenal bodies healthy. Small intestine pink in color; the agminated glands thickened, and mostly bright-red in color; the lower glands were a line in thickness, and contained a white cellular deposit; none of them were ulcerated. Mesenteric glands somewhat enlarged. Mucous membrane of the large intestine dirty slate colored, with streaks of inflammation here and there. In a later examination of the removed viscera several growths of connective tissue, hardened by calcareous deposits, were found attached to the end of the vermiform appendix.—Acting Assistant Surgeon Joseph Leidy. [Nos. 88 to 92, Medical Section, Army Medical Museum, are from this case. Nos. 88, 89, and 90 are successive portions of the ileum, in each of which is a large thickened Peyer's patch; the coats of the ileum are very thin. In No. 90 the patch is remarkable for its great size and the pultaceous character of the thickening; there are also several enlarged solitary follicles in this specimen. No. 91 is a portion of the cæcum with the appendix vermiformis, at the extremity of which are several tumors of connective tissue, which are hardened by calcareous deposits. No. 92 is a perpendicular section of the left lung, with pleuritic adhesions on its surface, and partial hepatization of the lower lobe.]

CASE 164.—Private Charles Frink, company D, 68th New York volunteers; admitted from Washington, December 18, 1862. Diarrhœa. Died, December 21st. *Autopsy* next day: Body slightly emaciated; chest and abdomen with a few spots of purpura; feet œdematous, swollen, and purple; an ulcerated bubo in the groin; sordes on the lips, teeth, and tongue. Brain, heart, and lungs healthy. Stomach and liver healthy. Spleen pale and somewhat soft. Kidneys healthy. Small intestine rather bright pink throughout; the lower part of the ileum inflamed, the last two feet intensely; solitary and agminated glands enlarged and inflamed, the degree of enlargement increasing in the descent of the intestine; in the lower two feet of the ileum the solitary glands were enlarged to the size of pepper-corns, and most of them presented a central ulcer; the lower agminated glands were also exceedingly enlarged, and the lowest superficially ulcerated. The large intestine was dark slate color, with streaks and patches of inflammation throughout.—Acting Assistant Surgeon Joseph Leidy.

CASE 165.—Private Lewis A. Wood, company E, 20th Michigan volunteers; admitted December 13, 1862, from the army of the Potomac. Chronic diarrhœa. Died, December 26th. *Autopsy* next day: Apparent age about 22 years; body rather emaciated; spots of purpura on the trunk. Recent pleurisy on both sides, most marked on the right side, and especially at the back part, where there was a considerable quantity of pseudomembrane; the lower lobe of the left lung was covered with a thin pseudomembrane, but the pleurisy did not extend upon the upper lobe. Pneumonia, with condensation of the lower lobe of the right lung, and lobular pneumonia of the upper lobe. Pneumonia of the lower lobe of the left lung, with condensation,

except at the anterior inferior edge, which was free from inflammation; lobular pneumonia of the upper lobe of the same lung. Inflammation of the bronchial mucous membrane. Liver enlarged, measuring twelve inches by seven and a half, and three and a half; firm, reddish-brown on the surface, but deeper red at the back part of the right lobe, mottled with red points; on section the lobuli presented a brownish-drab color, with thick, dark-red centres. Spleen large, seven and a half inches by five and three; firm, with marks of an old inflammation at the lower part. Moderate inflammation diffused through the ileum and colon. Enlargement of the solitary glands in patches here and there in the lower part of the ileum; slight thickening and reddening of the agminated glands. Slight enlargement of the solitary glands of the large intestine, but with no black deposit.—Acting Assistant Surgeon Joseph Leidy. [Nos. 107 to 109, Medical Section, Army Medical Museum, are from this case. Nos. 107 and 108 are successive portions of the ileum, in which the solitary follicles are enlarged to the size of small shot; each piece exhibits an apparently healthy Peyer's patch. No. 109 is the enlarged spleen described above.]

CASE 166.—Private Edward Campbell, company C, 43d New York volunteers; admitted from Harrison's Landing, Virginia, August 10, 1862. Diarrhœa. December 1st there was less diarrhœa, but the patient suffered from anorexia, and was weak and scorbutic in appearance. December 10th there was but little diarrhœa, but great prostration and increasing emaciation; the eyes were sunken, and he presented the peculiar look common in fatal cases of Chickahominy diarrhœa. Died, December 29th, at 7 A. M. *Autopsy* same day: Apparent age about 30 years; body exceedingly emaciated; spots of purpura on the trunk. Heart and lungs healthy. Stomach with a streak of inflammation along the lesser curvature, but generally healthy. Liver small, rather bright reddish-brown, firm; gall-bladder absolutely empty. Spleen small, Indian-red on section. Pancreas and kidneys healthy. Slight inflammation in small patches, with a few ecchymoses here and there, in the ileum. Cæcum filled with impacted boiled eggs; the mucous membrane dark-red, and with a few small blackened ulcers. Slight diffused inflammation through the colon; a few small patches of greater intensity, and a number of superficial ulcers. Lower part of sigmoid flexure and rectum intensely inflamed, red with blackish spots, and a multitude of small ulcers extending into the submucous tissue. No disease of the intestinal glands; only a few of the lowest agminated glands containing a small quantity of black deposit.—Acting Assistant Surgeon Joseph Leidy.

CASE 167.—Corporal Reuben Smith, company B, 6th Maine volunteers; age 40; admitted November 13, 1862. Chronic diarrhœa after remittent fever. Died, December 29th. *Autopsy* four hours after death: Body exceedingly emaciated; lower extremities œdematous, especially the left one. Heart healthy. Both lungs attached throughout by old pleuritic adhesions; the right lung was healthy, except that it contained in its apex a cavity about the size of a walnut; left lung for the most part healthy, there being several condensed masses of tissue, indicating lobular pneumonia, in the back part of the lower lobe. Mucous membrane of the stomach exceedingly pale—the cavity contained a quantity of milk-punch. Liver with old adhesions of the upper surface; the tissue somewhat fatty in appearance, being yellowish-brown and soft. Spleen, with old adhesions on the convex surface, small, and on section pale. Pancreas and kidneys healthy. The small intestine appeared healthy. The mesenteric glands were all enlarged, many of them to the size of pigeons' eggs, and were filled with soft, pasty, tuberculous matter. Large intestine with moderate diffused inflammation, accompanied with small patches here and there of greater intensity; these patches were covered with shreds of pseudomembrane and desquamated epithelium. The lower part of the sigmoid flexure and rectum were intensely inflamed, and coated with pseudomembrane and desquamated epithelium. The mucous membrane of the colon was exceedingly soft, and presented a number of follicular ulcers.—Acting Assistant Surgeon Joseph Leidy. [Nos. 110 and 111, Medical Section, Army Medical Museum, are from this case. The specimens are successive portions of the descending colon, with irregular patches of pseudomembrane on the mucous surface, and a few small follicular ulcers.]

CASE 168.—Private Richard Goggin, company E, 22d Massachusetts volunteers; age 25; English; admitted December 18, 1862, from Harewood hospital, Washington, D. C. Phthisis pulmonalis. Died, December 31st. [This man is recorded in the register of Harewood hospital, admitted November 19, 1862—bronchial catarrh—transferred to Philadelphia December 17th.] *Autopsy:* Body not much emaciated; skin waxen; no spots of purpura. Recent pleurisy, with pseudomembranous attachment throughout, on both sides. Extensive tubercular deposit of recent origin throughout both lungs, besides a few old tubercles, together with several small cavities the size of filberts, at the apices of the lungs. Bronchitis; enlargement of the bronchial glands. Heart soft and flabby, and easily lacerable; its cavities distended with currant-jelly-like clots. Liver soft, but otherwise apparently normal. Spleen of medium size, with condensation and blackening of portions of its structure, as evidences of former inflammation. Stomach, pancreas, and kidneys normal. Lymphatic glands of the abdomen generally somewhat enlarged through an increase of the corpuscular element. Tuberculous deposit, accompanied with ulcers, in the lowest agminated glands. Most extensive ulceration of the mucous membrane of the cæcum. A few small tubercles here and there in the walls of the much-contracted colon. Ecchymosed spots here and there in the ileum, and small irregular patches at the ascending and terminal portions of the large intestine.—Acting Assistant Surgeon Joseph Leidy. [No. 86, Medical Section, Army Medical Museum, is from this case. The specimen consists of the lower extremity of the ileum and part of the cæcum. A large Peyer's patch just above the ileo-cæcal valve, and several of the solitary follicles of the ileum are ulcerated. In the cæcum there are a number of irregular excavating ulcers, with thickened overhanging edges.]

CASE 169.—Private Samuel S. Snyder, company K, 132d Pennsylvania volunteers; age 21; admitted from Fairfax Seminary hospital, Virginia, December 16, 1862. Typhoid fever. [The records of Fairfax Seminary hospital show that this man was admitted December 13th—diagnosis chronic rheumatism—and was transferred to Philadelphia December 15th.] Died, January 9, 1863. *Autopsy* the same day: Body very much emaciated; skin ecchymosed on the trunk and extremities. Heart, lungs, liver, spleen, pancreas, stomach, and kidneys healthy. Mucous membrane of the ileum slightly inflamed; the agminated and solitary glands white and slightly enlarged. Mucous membrane of the colon intensely inflamed throughout, softened, and everywhere covered with a thin broken layer of white pseudomembrane, adherent tightly, and composed of pyoid corpuscles; there were also a multitude of ecchymosed spots not larger than flea-bites; the solitary glands were inconspicuous, and appeared not to be diseased.—Acting Assistant Surgeon Joseph Leidy.

CASE 170.—Corporal Charles Gerberding, company F, 52d New York volunteers; admitted from Alexandria, Virginia, December 13, 1862. Diarrhœa and tonsillitis. [The records of the 2d division hospital, Alexandria, Virginia, show that this man was admitted November 6, 1862—diagnosis acute diarrhœa—and transferred to another hospital December 12th.] Died January 11, 1863, at 10 P. M. *Autopsy* next day: Apparent age about 45; body greatly emaciated. The fauces and part of the pharynx exhibited rather thick white patches of pseudomembranous matter without ulceration, (diphtheria?) Lungs and heart healthy. Liver red-ochre colored, not enlarged, but somewhat fatty. Spleen small, but apparently healthy. Stomach, pancreas, and kidneys without apparent disease. Mucous membrane of the ileum paler than usual, except that there were a few small patches of moderate inflammation; the solitary and agminated glands contained black deposit, but otherwise appeared natural. The large intestine presented seven patches of inflammation about the size of the hand, nearly equidistant, the first in the cæcum, the last at the sigmoid flexure of the colon; there were also small ecchymosed spots, and the solitary glands contained black matter, but there were no ulcerations in any part of the intestinal canal. The case appeared as if it had been one of convalescing Chickahominy diarrhœa, in which the patient died of exhaustion before the cure had been carried out. The blood presented an impoverished condition as relates to the quantity of blood corpuscles, though there appeared to be no change of relation between the number of red and white corpuscles.—Acting Assistant Surgeon Joseph Leidy.

CASE 171.—Private Dennis O'Keef, company F, 6th Maine volunteers; age 45; admitted from Washington, D. C., December 18, 1862. Intermittent fever. [The register of the Odd Fellows' Hall hospital, near the Navy Yard, Washington, shows that this man was admitted to that hospital November 17th, and transferred to another hospital December 17th; no diagnosis.] Died, January 22, 1863. *Autopsy* the same day: Body exceedingly emaciated; skin tinged with bile. Heart and pericardial liquor tinged with bile; the right auricle and ventricle each with a white opaque membranous patch the size of a quarter dollar. Lungs with old adhesions throughout, but otherwise healthy. Liver enormous, extending down the front of the abdomen so as to cover half the remaining contents; its surface was dull-brown, and coarsely nodulated; the right lobe contained a large multilocular abscess, filled with a pint or more of thick greenish-yellow pus; the left lobe contained a smaller abscess of the same kind; gall-bladder very small, filled with bile resembling coal-tar in color and consistence. Peritonitis. The small and large intestines covered with thin recent pseudomembranous matter. The stomach empty, apparently healthy. Pancreas dense. Spleen small but healthy. Ileum with the mucous membrane moderately inflamed and blackened. Colon exceedingly contracted; in the middle of its course not more than three-quarters of an inch in diameter, and all appearance of sacculi obliterated; its mucous membrane greenish-black, with streaks of inflammation and a few ecchymosed spots. All the intestines were empty, except a small quantity of brownish tenacious mucus, which was exceedingly fetid, adhering to the sides.—Acting Assistant Surgeon Joseph Leidy. [No. 333, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the right lobe of the liver, in which there are a number of irregular communicating abscess cavities, the largest four inches in long diameter.]

CASE 172.—Private James Litzenberg, company A, 26th Pennsylvania volunteers; age 40; German; admitted from Washington, D. C., December 12, 1862. Diarrhœa. [The register of Carver hospital, Washington, shows that this man was admitted to that hospital November 20, 1862—diagnosis rheumatism—and transferred to another hospital December 11th.] Died, January 22, 1863. *Autopsy* the same day: The body looked as if the patient had been, before his illness, of great vigor and muscular strength, but was now emaciated. Brain healthy. Right lung with old adhesions to the costal pleura; the apex with a tubercle the size of a marrow-fat pea, and several small ulcerated cavities; left lung with a few tubercles about the size of pepper grains in its apex and scattered at the back part of the upper lobe. Pericardium with about a teacupful of liquor. Heart flabby, with a large white clot in the right ventricle. Spleen flabby, reddened, and roughened on the surface, (apparently the evidences of an old inflammation;) structure very soft purplish red. Solitary and agminated glands of the ileum slightly enlarged, and opaque white. Colon with the mucous membrane soft, grayish, with a few red streaks of inflammation and a few ecchymosed spots. Remaining organs apparently healthy.—Acting Assistant Surgeon Joseph Leidy. [Nos. 84 and 85, Medical Section, Army Medical Museum, are from this case. The specimens are successive portions of the ileum, showing pin-head enlargement of the solitary follicles and slight thickening of Peyer's patches.]

CASE 173.—Private William Powers, company D, 1st United States chasseurs; admitted from Fairfax Seminary hospital, Virginia, December 16, 1862. Phthisis and diarrhœa. Remarks by Acting Assistant Surgeon H. West: This man was transferred to this hospital December 16, 1862, from an Alexandria hospital. The diagnosis then made was phthisis. There was no dulness on percussion, but the respiration was at times cavernous, and at times much obstructed. I was not able to make as careful an examination as I should have liked, owing to the vermin which, in his condition, it was impossible entirely to destroy. During the whole time he was under my care the treatment was palliative and strengthening, viz: Cod-liver oil and iron, stimulants and morphia, chalk-mixture and laudanum, with astringents, were used to check the exhausting diarrhœa. [The register of the Fairfax Seminary hospital shows that this man was admitted to that hospital December 7, 1862—diagnosis chronic diarrhœa—and transferred to Philadelphia December 15th.] Died, February 1, 1863. *Autopsy:* Body extremely emaciated. About a gill of liquid in the pericardium. Heart somewhat enlarged, due to dilatation of the right ventricle, the walls of which were about two lines thick, and the cavity contained a large and recent white fibrinous clot. The right lung was healthy, and without old adhesions; the left lung for the most part was healthy, except that the inferior anterior angle was affected with pleuro-pneumonia, forming an indurated mass the size of an egg, adhering by recent pseudomembrane to the neighboring reflected pleura; the base of the lower lobe was affected with recent pleurisy, as indicated by engorgement of the subserous capillaries and a band of pure white pseudomembrane about two lines wide fringing the lower acute margin of the lung; inflammation of the tracheal and bronchial mucous membrane. Liver nearly uniformly brown on the surface and on section; gall-bladder entirely empty. Spleen small, indurated, and attached throughout by old adhesions. Kidneys healthy. Stomach and small intestines distended with air; the lower fifteen inches of the ileum affected with pseudomembranous inflammation; the agminated glands containing black deposits. The colon contracted; its mucous membrane exceedingly corrugated, inflamed, generally of a slate color, with darker patches and spots of the same, and pseudomembranous matter adherent from one end to

the other; the pseudomembranous matter adhered tightly, was fibro-granular in structure, and replaced the columnar epithelium, which appeared normal in the intervals of the pseudomembranous shreds; the dark patches of coloring matter were produced by the deposit of black globules about half the size of blood disks and smaller.—Acting Assistant Surgeon Joseph Leidy. [Nos. 55 to 59, Medical Section, Army Medical Museum, are from this case. No. 55 is the spleen, with numerous peritoneal adhesions. No. 56 is a portion of the ascending colon, with small patches of pseudomembrane adherent to the mucous surface, and ulceration of some of the solitary glands. No. 57, from further along the colon, presents more numerous and better marked follicular ulcers. No. 58, from the transverse colon, presents fewer ulcerated follicles, but the small pseudomembranous patches are more numerous. No. 59, from the descending colon, exhibits still larger pseudomembranous patches and still fewer ulcers. The coats of the colon are thickened in all these pieces, and many of the solitary follicles, instead of ulcerating, have been converted into cysts, the largest of which are about the size of peas. This condition is most noteworthy in No. 57.]

CASE 174.—Private Joseph Kessinger, company C, 5th Wisconsin volunteers; admitted from Fairfax Seminary hospital, Alexandria, Virginia, December 16th. Chronic diarrhœa. Treatment: Cough mixture, pills of opium, ipecacuanha, and acetate of lead, milk-punch, beef-essence, extra diet. [The register of Fairfax Seminary hospital shows that this man was admitted to that hospital December 13, 1862—diagnosis chronic diarrhœa—and transferred to Philadelphia December 15th.] Died, February 6, 1863. *Autopsy* same day: Age about 35 years; emaciation extreme. Heart and lungs healthy. Liver pale red; gall-bladder empty. Spleen Indian-red on section. Stomach and pancreas healthy. The ileum inflamed, more especially at its lower extremity; the lower agminated and solitary glands intensely reddened, and the lowest four of the former ulcerated through at their centres to the muscular coat of the intestine; the middle agminated glands containing black deposits, the upper ones healthy. Colon much contracted; its mucous membrane exceedingly corrugated and considerably inflamed, especially within the cæcum.—Acting Assistant Surgeon Joseph Leidy.

CASE 175.—Private Alfred E. French, company K, 5th Vermont volunteers; age 21; admitted from Harrison's Landing, Virginia, August 10, 1862. Chronic diarrhœa, contracted while on the Chickahominy. Note by Acting Assistant Surgeon L. K. Baldwin: This patient came under my charge October 1, 1862. His diarrhœa was not at any time excessive, but he was very weak. There was considerable gastric irritation and dyspepsia, which yielded in a great measure to the use of subnitrate of bismuth and low diet. He gained sufficiently to be able to move about, and was made to walk out whenever the weather would permit. He seemed to improve until about two weeks before his death, when he began to complain of a severe pain in the right side, with symptoms resembling pneumonia. Toward the last the stomach was so irritable that but little food was retained. There was not much diarrhœa during the last two weeks of his life. Died, February 18, 1863, at 8 A. M. *Autopsy* same day: Body emaciated; skin sallow. Brain large, unusually pale; vessels of the pia mater for the most part empty; sub-arachnoid space distended with serous liquid containing some pus; at the base of the brain, in several portions of the same space there were small accumulations of pus, especially in the fourth ventricle, which contained about four or five minims of pure pus; arachnoid everywhere dull whitish; in many places, especially along the course of the larger vessels, and at the edges of the great longitudinal fissure, with a subjacent, adherent, soft, yellowish, fibrinoid matter. (Evidently the anatomical characters of meningitis, though its existence was not suspected during life.) On the convex surface of the left cerebral hemisphere there were three small ecchymosed spots; interior of the brain apparently healthy. Left lung with old adhesions to the costal pleura, but the tissue healthy; right lung with slight old adhesions at the back part of the upper lobe, which was in an early stage of pneumonic induration; the middle and lower lobes healthy. Heart healthy. Stomach containing a considerable quantity of clear glairy liquid mingled with bile, which deeply stained the mucous membrane. Liver large, brown in color, apparently healthy. Spleen consistent, reddish-brown on section. Ileum with slight inflammatory streaks here and there, and with a small patch of moderate inflammation near the lower end; the glands were healthy, except that the lowest agminated glands contained black matter. Slight inflammation of the cæcum, and rather more redness than natural in most parts of the colon, the solitary glands of which contained black matter. Kidneys partly congested and partly pale; the pale portions presented many of the cells with more fat than natural. Supra-renal bodies healthy.—Acting Assistant Surgeon Joseph Leidy.

CASE 176.—Private Peter Quinn, company H, 63d Pennsylvania volunteers; admitted July 7, 1863, for contusion of the foot received at Gettysburg, Pennsylvania. The ball or shell had struck on the dorsum of the foot, and produced much pain and inflammation. He was unable to bear any weight on the ankle. A cold-water dressing was applied, and the patient so far recovered that on the 19th he was able to walk without the aid of cane or crutches. On this date diarrhœa commenced, and was treated successfully; whereupon he obtained a pass for one day, but was absent four. By questioning him closely, I learned that he had been on a debauch, and had been in the guard-house. The foot was now swollen and the diarrhœa tending to dysentery. He complained but little of pain, but much of debility. The age of the patient (sixty-three years) was considered, but his debility attributed to his recent spree. Pills of two grains of quinine and half a grain of opium were ordered every three hours, half an ounce of brandy every two hours, and a laudanum enema. The stools, however, grew more bloody and frequent during the day; counter-irritants were applied to his abdomen. On the evening of August 4th he was delirious, and walked about the ward. On the morning of the 5th he was found sinking rapidly, and stimulants were given more freely; at 10 A. M. he attempted to get out of bed to stool, but fainted, after which he was unable to speak distinctly, and died at 11.30 A. M. *Autopsy* same day: Body emaciated. Extensive old pleuritic adhesions on both sides. Parenchyma of lungs healthy. Old adhesions about the spleen. Pseudomembranous inflammation of the entire large intestine. Other organs healthy.

CASE 177.—Private Robert Bedell, company H, 74th New York volunteers; age 45; admitted June 25, 1863, from Harewood hospital, Washington, D. C. Chronic diarrhœa. [The records of the regimental hospital of the 74th New York show that this man was admitted to that hospital, then at Camp Kearney, near Alexandria, Virginia, October 29, 1862, for diarrhœa, and returned to duty October 30th. He was again admitted to regimental hospital, then at Camp Sickles, near Manassas, Virginia, November 4th, with the same disease, and returned to duty November 5th. He was admitted a third time to regimental hospital, then near Warrenton Junction, Virginia, November 12th; the diagnosis recorded is dysentery. He was returned to duty November 18th. He was admitted a fourth time to regimental hospital, then near Fredericksburg, Virginia,

February 8, 1863—dysentery—and returned to duty February 9th; the regimental hospital still remaining near Fredericksburg, he was treated for the fifth time, from February 12th to February 14th, and a sixth time, from March 5th to April 19th, the diagnosis now being diarrhœa. April 19th he was transferred to general hospital. He next appears on the register of the Harewood hospital, Washington, D. C., where he was admitted June 14th, for chronic diarrhœa, and transferred to Philadelphia June 24th.] Died, September 22d. *Autopsy:* Body well nourished; suggillation posteriorly. There were a few old adhesions of the right lung to the pleura and diaphragm; the left fifth rib was bifurcated. Large clots were found in both sides of the heart, especially in the right; the pericardium contained half an ounce of fluid. The liver and gall-bladder were healthy. The spleen was small. The stomach inflamed throughout, especially near its cardiac orifice. The ileum was congested on the peritoneal surface, internally inflamed throughout; Peyer's patches were not thickened. The colon was inflamed and thickened.—Acting Assistant Surgeon E. A. Smith.

CASE 178.—Private Henry C. Durham, company G, 30th United States colored troops; age 29; admitted from City Point, Virginia, August 20, 1864. Chronic diarrhœa of two months' duration. [The register of the hospital for colored troops, City Point, Virginia, shows that this man was admitted August 14, 1864—no diagnosis—and transferred to another hospital August 17th.] The patient stated that he had been subject to pains in the breast and occasional colds for several years. He was much emaciated and debilitated, complained of a dull pain in the epigastrium, and vomited nearly all his meals. His breath was very fetid. A diarrhœa mixture was prescribed, and compound tincture of cinchona to be taken before meals. September 2d: The gastric symptoms still continue; bowels very loose. The vomiting was temporarily checked by lime-water and milk, but soon recurred; creasote was therefore tried in half-drop doses four times daily; this, however, seemed to increase the pain, and put no stop to the fetor of breath. September 6th: Grows steadily worse. To take twelve grains of subcarbonate of bismuth four times a day. September 7th: Is able to eat a little; the fetor of the breath is increasing; the stools are purulent. September 9th: Stop the subcarbonate of bismuth, and give twenty drops of oil of turpentine four times a day. Died. September 10th. *Autopsy:* The lungs presented nothing abnormal except that the left lung was everywhere adherent to the thoracic parietes. The heart was small. The liver was healthy. The spleen was exceedingly small. The stomach and the large intestine were congested, and the rectum extensively ulcerated.

CASE 179.—Private William Otis, company I, 153d New York volunteers; age 45; admitted from camp October 30, 1864. Chronic diarrhœa. [The register of the field hospital, Sandy Hook, Maryland, shows that this man was admitted to that hospital September 9th—no diagnosis—and transferred to another hospital September 10th. The register of the 1st division of the Annapolis hospital, Maryland, shows that he was admitted to that hospital September 10th, and transferred to the hospital at Camp Parole, Annapolis, Maryland, October 8th. The register of Camp Parole hospital shows that he was admitted October 8th—dropsy—and transferred to Baltimore October 12th. The register of Patterson Park hospital, Baltimore, shows that he was admitted to that hospital October 13th—convalescent—and transferred to Newton University hospital October 17th. The register of Newton University hospital shows that he was admitted to that hospital October 18th—gastritis—and transferred to Philadelphia October 23d.] When admitted to this hospital he had thin, frequent stools; was much exhausted and feverish. Ordered pills of acetate of lead, opium, and camphor during the day; two grains of blue mass at night. November 4th: Complains of pain in the chest; there is, however, no cough and no abnormal expectoration. The stools are less frequent, but he has a good deal of hiccough; the latter symptom, however, was relieved by carminatives. November 6th: Has constant nausea and vomiting. Stop medicine and give lime-water and milk. November 8th: The nausea yielded after a few doses of lime-water and milk. This morning, the bowels not having been moved for over twenty-four hours, an injection was given, which produced a dark, thin discharge. The patient seemed very feeble, and sank rapidly in spite of the free administration of stimulants. He died at 7.30 P. M. *Autopsy* thirty-six hours after death: The brain was healthy. The lungs were much congested. There was a large coagulum of fibrin in the right side of the heart; the right ventricle was dilated; the left auricle contained a large clot of soft, black blood. The liver was somewhat fatty. The spleen and kidneys were healthy. The lower part of the ileum and the colon were inflamed.

CASE 180.—Private William M. Henderson, company G, 187th Pennsylvania volunteers; age 37; admitted November 12, 1864, from furlough. Chronic pleurisy. This man stated that he was taken sick with diarrhœa July 3d, while with his regiment at Petersburg, Virginia, and was sent to division hospital. He remained there about a week, and was sent to City Point July 11th. He was then dropsical. August 1st he was transferred to David's Island, New York harbor; he still had symptoms of dropsy. August 9th he was furloughed for thirty days, and ordered to report, on returning from furlough, to the medical director at Philadelphia. When his furlough expired he was too sick to report, and his attending physician obtained an extension of his furlough for thirty days. At the expiration of this time he was still too sick to report, and got thirty days more. November 11th he reported to the medical director in Philadelphia, and was sent to this hospital. [The register of the field hospital of the 1st Division, 5th Army Corps, shows that this man was admitted to that hospital July 4, 1864—anasarca—and sent to City Point, Virginia, July 11th. The register of the depot hospital of the 5th Army Corps, City Point, Virginia, shows that he was admitted to that hospital July 11th—Bright's disease—and sent to New York harbor. The register of the De Camp hospital, David's Island, New York harbor, shows that he was admitted to that hospital August 6th—dropsy—and furloughed August 9th, with orders to report in Philadelphia on the expiration of his furlough.] He died November 21st. *Autopsy* the same day: The lower extremities were somewhat œdematous. The membranes of the brain were congested, and there was a good deal of effusion in both lateral ventricles; the substance of the brain was softened and somewhat congested. There were slight pleuritic adhesions on the right side; the right lung had four lobes, and was very pale. There were strong pleuritic adhesions on the left side, and the left lung was bright red. The bronchial tubes were inflamed and full of pus. The left ventricle of the heart was dilated and somewhat hypertrophied; the valves were healthy; both ventricles contained coagula of black blood; the right auricle contained a fibrinous coagulum. The liver was enlarged and fatty; the gall-bladder distended with black bile. The spleen, kidneys, stomach, and small intestine were healthy. [The condition of the large intestine is not recorded.]

CASE 181.—Private Anton Stadler, company D, 12th Maine volunteers; age 55; admitted from field hospital October 25, 1864. Chronic diarrhœa. This man left his regiment October 19th. He stated that he had suffered from diarrhœa for a month previously. To take quarter of a grain of opium and two grains of tannic acid every three hours. Full diet. November 5th: He had a chill, followed by fever. To take two grains of sulphate of quinine every two hours. November 7th: There has been no recurrence of the chill. To take ten drops of tincture of the chloride of iron and a grain of quinine three times daily. January 27, 1865: The patient is improving. Furloughed twenty days. February 9th: Returned from furlough at 8 o'clock this evening; was carried in on a stretcher. Has pneumonia, and is very much prostrated. Ordered carbonate of ammonia, milk-punch, beef-tea, &c. Died, February 10th. *Autopsy* thirty-six hours after death: The right lung was bound firmly to the walls of the chest throughout; there were no adhesions on the left side; the apex of the right lung contained a large mass of tubercle; the whole of the right lung, from apex to base, was solidified; the inflammation in the upper and middle lobes had passed into the third stage; the lower lobe was still in the second stage; a few tubercles were found in the apex of the left lung; in other respects the left lung was healthy. [The condition of the intestinal mucous membrane is not recorded.]

The next three cases are from the case-book of the CUYLER HOSPITAL, Philadelphia, Pennsylvania, Surgeon Josiah Curtis, U. S. V., in charge at the date of the first case; Assistant Surgeon Henry S. Schell, U. S. A., at the time the others were recorded:

CASE 182.—Corporal William H. Everett, company C, 5th Maine volunteers; age 29; admitted May 13, 1863. Chronic diarrhœa. [He appears on the register of the regimental hospital of the 5th Maine, admitted March 20, 1863—chronic diarrhœa—sent to general hospital April 18th. The register of the hospital of the 1st Division, 6th Army Corps, records him admitted April 18th—chronic diarrhœa—sent to Washington, D. C., April 21st. He is borne on the register of the Harewood hospital, Washington, admitted April 21st—chronic diarrhœa—sent to Philadelphia May 9th.] This man stated that he was taken sick with diarrhœa in January last. He was treated in the Broad and Prime streets hospital for several days, and his diarrhœa was temporarily checked. He was brought to this hospital on a stretcher. When admitted he was much emaciated; his voice was very feeble; pulse small and feeble; eyes sunken; the temperature of his surface low. Treatment: Acetate of lead and opium, quinia, brandy, &c. Died, May 14th. *Autopsy* eleven hours after death: Brain not examined. There were no pleuritic adhesions; the left lung was somewhat congested; the right lung contained an unusual quantity of black pigment, and had a white cheesy mass in the upper part of its middle lobe. The heart was normal in size and appearance; its right cavities contained a fibrinous clot. The liver was somewhat congested, but normal in size and appearance; the gall-bladder was distended with normal looking bile. Some of Peyer's patches were quite large, but none of them were ulcerated. [The condition of the large intestine was not recorded.]—Acting Assistant Surgeon William Darrach, jr.

CASE 183.—Private William Whitmore, company C, 90th Pennsylvania volunteers; age 38; admitted October 2, 1863. Diarrhœa. [The records of the regimental hospital of the 90th Pennsylvania, then serving with the army of the Potomac, show this man admitted September 1, 1863—rheumatism—sent to general hospital September 16th. He is borne on the register of the Columbian hospital, Washington, D. C., admitted September 16th—contusion—transferred to Philadelphia October 1st.] This patient stated that he had suffered more or less from diarrhœa since the spring of 1862. He was under the charge of Acting Assistant Surgeon Dunton for about eight months in this hospital, and improved somewhat in general health, having been exceedingly debilitated and emaciated when admitted. When first seen by the reporter, in June, 1864, he had every day three or four watery stools unaccompanied by pain, and was still weak, with excessive thirst and deficient appetite. The treatment adopted was tonic, astringent, and nutritive, and he seemed gradually to improve, the number of stools being reduced to two daily. On the evening of August 2d he returned from a pass very much intoxicated, and in the course of the night was attacked with acute abdominal pain, with coldness of the extremities, and died next day. *Autopsy:* The brain was not examined. The lungs and heart were healthy. The liver was somewhat softened; the gall-bladder distended with bile. The spleen was small and shrivelled. The stomach and intestines were much congested. The ascending and transverse colon presented numerous ulcerations.—Acting Assistant Surgeon P. D. Keyser.

CASE 184.—Wagoner George A. Gleek, company I, 1st Michigan cavalry; age 37; admitted August 30, 1864. Chronic diarrhœa of three months' standing. [The register of the post hospital of the cavalry division, Camp Stoneman, D. C., shows that this man was admitted to that hospital August 2, 1864, with diarrhœa, and sent to Lincoln hospital August 11th. He appears on the register of Lincoln hospital, Washington, D. C., admitted August 12th—incontinence of urine—sent to Philadelphia August 29th.] He was much emaciated, and his skin had a peculiar tan color. He had no appetite, was much debilitated, and kept his bed the greater part of the time. He had frequent stools and considerable abdominal pain. The treatment adopted was tonic, astringent, and anodyne, with nutritious food, and stimulus graduated according to his condition. He slowly sank, and died October 24th. *Autopsy* next day: Rigor mortis well marked; body greatly emaciated. The brain was not examined. There were extensive pleuritic adhesions, both old and recent, on the left side; both lungs contained abundant pigment deposits. The heart and pericardium were healthy. The omentum almost entirely devoid of fat. The stomach was slightly congested. The spleen enlarged. The small intestines presented numerous ulcers in the neighborhood of the ileo-cæcal valve. The remaining viscera appeared to be normal.

The following case was forwarded on a medical descriptive list from the MCCLELLAN HOSPITAL, Philadelphia, Pennsylvania, Surgeon Lewis Taylor, U. S. A., in charge:

CASE 185.—Private Casper Shoenberger, company G, 61st Pennsylvania volunteers; age 27; admitted from Sandy Hook, Maryland, September 27, 1864. Bright's disease of the kidneys. [The register of the field hospital, Sandy Hook, Maryland, reports this man admitted September 25, 1864—dropsy—sent to general hospital September 26th.] The urine was albuminous,

and there was general anasarca. The disease pursued its usual course until October 4th, when he had three convulsions of short duration. Next day he was attacked with dysentery of a severe character, and died October 9th. *Autopsy* twenty-four hours after death: The colon and rectum were found to be greatly inflamed and thickened. The kidneys were fatty. There were also two retrograde intussusceptions, eight inches apart, in the upper third of the ileum.—Acting Assistant Surgeon J. Orso Day.

The next two cases are from the case-book of the MOWER HOSPITAL, Philadelphia, Pennsylvania, Surgeon Joseph Hopkinson, U. S. V., in charge at the date of the first case; Surgeon Lewis Taylor, U. S. A., at the date of the second:

CASE 186.—Sergeant Michael Halloran, company F, 14th New York artillery; age 19; admitted from City Point, Virginia, July 26, 1864. Chronic diarrhœa. [This man is borne on the register of the hospital of the 1st Division, 9th Army Corps, City Point, Virginia, as admitted from regimental hospital July 14, 1864—diarrhœa and fever—sent to general hospital July 23d.] When brought in, the patient was much emaciated and prostrated. He had diarrhœa and obstinate vomiting; the matter vomited had a bilious character; the stools were greenish-yellow, watery, and accompanied by pain. Ordered small doses of calomel and morphia; also emulsion of turpentine; milk-punch and beef-essence. July 27th: No change; the vomiting is persistent. Applied a mustard plaster to the abdomen. July 28th: Vomits less; diarrhœa about the same. To use stimulants freely. Died, August 3d. *Autopsy*: The mucous membrane of both the large and the small intestines was inflamed and ulcerated. There was intense congestion of the portal circulation, and the liver was enlarged.

CASE 187.—Private Peter Woodley, company D, 115th United States colored troops; age 25; admitted July 31, 1865. Chronic diarrhœa and scurvy. [This man appears on the records of the hospital at Whitehall, Pennsylvania, admitted May 20, 1865—convalescent—sent to general hospital June 26th. He is borne on the register of the Satterlee hospital, Philadelphia, admitted June 26th—chronic diarrhœa—sent to Mower hospital July 31st.] This man had symptoms which suggested consumption. He was treated with cod-liver oil, tincture of cinchona, and whiskey. Died, August 20th. *Autopsy* six hours after death: The right pleural sac was partially filled with fluid blood. The right lung was much congested; the left lung slightly congested; no tubercles were found in either lung. The pericardium was firmly adherent to the left ventricle of the heart; the auricles and valves of the heart were normal; the right ventricle was distended with fluid blood; the left ventricle contained a small clot. Everywhere else the blood was fluid. The liver was paler than normal, but not otherwise diseased, and the other abdominal viscera were apparently healthy. The abdominal cavity contained a considerable quantity of serum. The source of the hæmorrhage into the right pleural cavity was not satisfactorily made out.

The next three cases are from the case-book of the SUMMIT HOUSE HOSPITAL, Philadelphia, Pennsylvania, Surgeon J. H. Taylor, U. S. V., in charge:

CASE 188.—Private Reuben Peters, company B, 43d United States colored troops; age 21; admitted from Satterlee hospital, Philadelphia, September 29, 1864. Debility and diarrhœa. [This man is borne on the register of Satterlee hospital as admitted August 20, 1864—consumption.] September 30th: ℞. Tincture of catechu, paregoric, and tincture of ginger, of each half an ounce, tannic acid a drachm and a half. Take a teaspoonful every two or three hours; also a teaspoonful of tincture of cinchona four times a day. Full diet. October 4th: Very much improved. October 5th: No treatment. The patient remained in hospital comparatively well until November 23d, when he complained of a cough, for which an expectorant mixture was prescribed. In a few days the cough began to diminish, and December 3d he was put on duty as an attendant in the ward. December 6th: The diarrhœa has returned with considerable violence. Prescribed nitrate of silver and opium. Full diet. December 8th: To take ten drops of the tincture of the chloride of iron three times a day; four ounces of brandy daily. December 9th: His bowels were moved six to eight times yesterday; he is much debilitated. December 15th: Is improving; diarrhœa stopped; general condition good. December 19th: Complains of headache; pulse full, 90 to 95; tongue coated, but moist; skin dry. ℞. Tartar emetic one grain, ipecacuanha thirty grains; make two powders; the second to be given if the first does not produce emesis. December 21st: The diarrhœa is again troublesome. To take pills containing nitrate of silver. December 23d: The patient has all the symptoms of typhoid fever. December 24th: Prescribed quinine in solution. December 26th: A purge of calomel and rhubarb; symptoms of pneumonia have made their appearance, affecting the left lung more than the right; pulse 85 to 90, not very full; great prostration; tongue and lips dry; the patient is insensible. Quinine solution renewed; turpentine emulsion. December 27th: A blister applied to the chest. December 29th: No better. Carbonate of ammonia. December 31st: A pustule has made its appearance over the pupil of the right eye. Died, January 1, 1865. *Autopsy:* The mucous membrance of the bronchial tubes was inflamed; the lungs were extensively hepatized; the right lung adherent to the thoracic parietes. The heart was healthy; its right ventricle filled with blood. The liver was enlarged. [The condition of the alimentary canal is not recorded.]

CASE 189.—Private Frank Diggs, company I, 4th United States colored troops; age 20; admitted from Hampton hospital, Virginia, August 17, 1864. Chronic diarrhœa. [This man appears on the register of Hampton hospital, Fortress Monroe, Virginia, as admitted June 11, 1864, from the field—intermittent fever—transferred to Philadelphia August 15th.] He was treated at first with pills of acetate of lead and opium. Full diet. Under this treatment he improved until September 7th, when intermittent fever made its appearance, and was successfully combated by quinine. October 7th: Rheumatic symptoms were developed, and were treated with a combination of sulphate of cinchona and iodide of iron. Toward the close of the month he had a mild attack of tonsillitis, which, however, speedily subsided, and by November 5th he was able to do duty as a nurse. Toward the end of November the lymphatic glands of his neck began to enlarge, and were painted with tincture of iodine. The tonsils also again enlarged, and an abscess formed in the left tonsil, which discharged December 9th. Shortly after a severe bronchitis was

developed, and December 21st slight febrile symptoms made their appearance. December 22d: The symptoms have increased and have assumed a typhoid character; the patient was very restless last night, tongue moist but furred, pulse between 80 and 90, bowels open, fæces natural. A solution containing chlorate of potassa and sulphate of cinchona was prescribed, with cold applications to the forehead, and brandy. December 24th: The symptoms are those of fully developed typhoid fever: skin dry, tongue moist; the patient is greatly debilitated, very restless, and has a good deal of cough. Prescribed an emulsion of oil of turpentine combined with syrup of squill. December 30th: Erysipelas of the face has made its appearance. Continue treatment, with the addition of quinine. January 15, 1865: The patient is now fairly convalescent, but has considerable swelling of the tonsils, more marked on the left side. He was treated with tincture of gentian and quinine. January 22d: An incision was made into the left tonsil and a great deal of pus discharged. February 2d: Typhoid pneumonia set in, involving the left lung. Quinine was prescribed, and a mixture containing seneka, squill, and laudanum. February 4th: Substitute a mixture containing nitrate of potash and veratrum viride. February 7th: He is improving, but still feverish; the left tonsil is still discharging. ℞. Calomel sixteen grains, chlorate of potassa half a drachm, opium a grain and a half; make eight powders. Take one every hour; six ounces of brandy daily. February 13th: The fever has entirely subsided, and the patient seems to be making good progress toward recovery. February 22d: Stimulants stopped. March 2d: The diarrhœa has recurred. To take pills of acetate of lead and opium. March 7th: The diarrhœa continues; there is much debility; the tonsils are still discharging. To take fifteen drops of tincture of chloride of iron three times a day. March 11th: Renew the lead and opium pills, one to be taken after every stool. March 17th: Again has a severe cough and great debility. March 22d: Applied a blister to the breast, and gave a cough mixture containing squill and morphia. March 23d: Is greatly prostrated; expectorates daily almost a quart of bloody pus; pulse feeble and remittent; his respiration appears to be effected by the left lung only; no respiratory murmur is heard on the right side. Died, March 25th, of suffocation, after a short struggle. *Autopsy* thirty-six hours after death: The right lung contained a great number of tubercles, and two large cavities filled with pus were found in its upper lobe; in the upper lobe of the left lung also a great many miliary tubercles were found; the lower lobe was healthy. The mucous membrane of the intestine was ulcerated.—Acting Assistant Surgeon G. O. Shittler.

CASE 190.—Private James O'Keefe, company D, 65th New York volunteers; age 47; admitted from Jarvis hospital, Baltimore, Maryland, April 3, 1865. Fistula in ano and diarrhœa. [This man appears on the register of the depot field hospital, 6th Army Corps, City Point, Virginia, as admitted December 5, 1864, for a boil, and sent to general hospital December 25th. He appears on the register of the Jarvis hospital, Baltimore, Maryland, as admitted December 26th—fistula in ano. While in Jarvis hospital it appears, from the register of surgical operations, that the fistula was slit open January 30, 1865.] When admitted to this hospital the wound had not yet healed. The patient also has a troublesome cough, which set in after the operation. Prescribed an expectorant mixture, and applied a simple dressing to the wound. April 10th: Rubbed the chest with croton oil. Extra diet. April 18th: The cough continues and the patient is much debilitated; he has a troublesome diarrhœa. Ordered a pint of brandy daily. May 22d: The diarrhœa is better, the cough continues, the sputa are tenacious, frothy, and mixed with pus. May 24th: Is very weak; coughs incessantly; has great dyspnœa; pulse 112; the diarrhœa continues. Died, May 26th, at 5 P. M. A few minutes before death he asked for brandy, sat up to take it, and expired suddenly. *Autopsy* seventeen hours after death: Rigor mortis marked. Both lungs were filled with softened tubercles. The heart was small; its left ventricle contained some thin black blood. The liver, spleen, and kidneys were healthy. [The condition of the intestines is not recorded.]

The following case was forwarded, with the specimens, from the hospital at the corner of FIFTH AND BUTTONWOOD streets, Philadelphia, Acting Assistant Surgeon Aug. C. Bournonville, in charge.

CASE 191.—Private Peter Brandey, company D, 62d New York volunteers; admitted August 12, 1862. Intermittent fever and diarrhœa. Died, August 26th.—Acting Assistant Surgeon E. Hartshorne. [Nos. 148 and 149, Medical Section, Army Medical Museum, are from this case. The specimens are two successive portions of colon, the surface of which has been extensively eroded by ulceration, leaving, however, numerous little islets of intact mucous membrane, in many of which pinhead ulcers of the solitary follicles can be seen.]

The following case was forwarded, with the specimens, from the CHRISTIAN STREET HOSPITAL, Philadelphia, Surgeon John J. Reese, U. S. V., in charge:

CASE 192.—Private Joseph R. Reid, company H, 82d New York volunteers; admitted from Washington, D. C., December 14, 1862. Chronic diarrhœa and phthisis. [This man appears on the register of the Casparis hospital, Washington, as admitted December 2d—diarrhœa—sent to Philadelphia December 13th.] Died, December 31, 1862.—Acting Assistant Surgeon E. B. Vandyke. [Nos. 317 to 320, Medical Section, Army Medical Museum, are from this case. Nos. 317, 318, and 319 are successive portions of the ileum, presenting large irregular ulcers of Peyer's glands, which penetrate to the muscular coat. No. 320 is a portion of the colon considerably thickened, and presenting a number of large irregular ulcers, which penetrate to the muscular coat; a number of enlarged lymphatic glands appear on the peritoneal surface of the piece, on the line of the attachment of the mesocolon.]

The next seven cases are from the NATIONAL HOSPITAL, Baltimore, Maryland, Assistant Surgeon George M. McGill, U. S. A., surgeon in charge. The notes of sixty-one *post mortem* examinations, made by Dr. McGill while in charge of this hospital, were

printed by him on a hand-press in the hospital, and forwarded to the Surgeon General's Office.* From these notes the following abstracts have been made, which include all the autopsies reported by Dr. McGill from the National Hospital on cases of diarrhœa or dysentery:

CASE 193.—Private C. B. Kittle, 10th Wisconsin battery; age 32; admitted from the medical director's office January 10, 1865. Diarrhœa, with extremely irritable stomach and pain in the right iliac fossa. About the third day after admission low fever set in, with muttering delirium at night, and slight cough. Some fine crepitation was heard over the lower portion of the right lung. Died, January 16th.—Acting Assistant Surgeon J. G. Keller. *Autopsy:* Body emaciated; right side of chest, anteriorly, larger than the left. The brain was normal. There was red hepatization of the posterior third of the upper lobe of the right lung, the whole of its lower lobe, and the central portion of the lower lobe of the left lung; on pressure, the hepatized portions yielded an abundance of grayish puruloid fluid. Inflammatory spots and ulcers were observed in the lower portion of the ileum, and in the large intestine. One of the ulcers in the cæcum had perforated, and communicated with a small abscess containing about two ounces of dark-colored, offensive, caseous, puruloid matter, which burrowed between the iliacus internus and psoas magnus muscles; extravasation into the abdominal cavity had been prevented by adhesions of the cæcum and ascending colon to the abdominal parietes. The liver was congested, and about one-fourth larger than natural. The spleen was a little hard, of natural size; the lower part of its anterior border congested and black. The kidneys were pale, except in their inferior portions, which were congested and cherry-colored.—Assistant Surgeon George M. McGill, U. S. A. [No. 618, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the cæcum, with the ileo-cæcal valve and two inches of the ileum. There were several ulcers in the cæcum, one of which had perforated.]

CASE 194.—Private John Kreul, company K, 199th Pennsylvania volunteers; age 20; admitted December 2, 1864. Chronic diarrhœa. This patient had typhoid symptoms and partial coma at the time of admission. He was treated with emulsion of turpentine and beef-essence; his condition improved somewhat for a while, but the diarrhœa continued until death. His mind was not clear at any time after admission.—Acting Assistant Surgeon W. G. Smull. [This man appears on the prescription-book of the 199th Pennsylvania volunteers as admitted to regimental hospital October 13, 1864, with acute diarrhœa. October 20th the entry, intermittent fever, appears opposite his name; October 23d, catarrh; October 25th, intermittent fever; October 26th, sent to field hospital. He appears on the register of the field hospital of the 10th Army Corps, admitted October 26th—intermittent fever—sent to Base hospital October 27th. He appears on the register of the Base hospital, 10th Army Corps, Jones's Landing, Virginia, admitted October 27th—intermittent fever; but there is no record of his disposition.] Died, January 23, 1865. *Autopsy* same day: Slight rigor mortis; considerable emaciation. There was about an ounce of serum in the subarachnoid space, about a drachm in each lateral ventricle, and a small quantity in the fourth ventricle; the substance of the brain was flaccid. The pericardium contained about two ounces of fluid. The heart was small and contracted; both sides contained white fibrinous clots, which extended on the right side into the pulmonary artery, on the left into the aorta. The lungs were dark-colored, and congested hypostatically; the upper lobe of the left lung was adherent to the thoracic parietes, its lower lobe to the diaphragm. The stomach was flaccid, its mucous membrane grayish. There were patches of congestion in the jejunum and ileum, especially the latter. The mucous membrane of the cæcum and ascending colon was thin, and presented large spots of congestion; in the transverse colon there were a number of ulcers which corresponded in position to the line of one of the longitudinal muscular bands. The sigmoid flexure and the upper part of the rectum were studded with small whitish ulcers. The liver was small and hard; the gall-bladder contained some light-colored bile. The spleen was a little larger than normal, tough, dark-colored, and full of blood. The kidneys were congested; the urine slightly albuminous.—Assistant Surgeon George M. McGill, U. S. A.

CASE 195.—Private John Jordan, company H, 173d New York volunteers; age 30; admitted December 21, 1864. Chronic diarrhœa. [This man appears on the register of the hospital of the 173d New York as having been treated for malarial fever in April, 1864, while the regiment was at Alexandria, Louisiana, and for diarrhœa and fever from November 24th to December 6th at Camp Russell, Virginia.] He stated that he had been suffering from diarrhœa for two months. His tongue was dry and thickly coated; skin dry and yellow; bowels moved nearly every hour. Enlargement of the liver was diagnosticated. He was treated with small doses of blue mass combined with vegetable astringents, but the diarrhœa was not checked by these measures. January 17, 1865: Symptoms of pneumonia on the right side were observed; counter-irritants were applied and stimulants administered. Died, January 31st.—Acting Assistant Surgeon J. G. Keller. *Autopsy* twenty hours after death: Body extremely emaciated. Brain normal; it weighed thirty-eight ounces and a half. Heart pale and flabby. The lungs were unusually black, and contained a number of small abscesses; the right lung was œdematous, and contained, besides the abscesses, a few miliary tubercles. The right lobe of the liver was adherent to the diaphragm; just below the adhesions was a large firm-walled abscess containing about a quart of gray odorless pus; the gall-bladder was quite full of yellow bile. Spleen very firm and dark-red; it weighed nine ounces and a half. Kidneys light-colored; weight six ounces each. The ileum was somewhat congested, and there were a number of small dark-bottomed ulcers in its lower portion, but Peyer's glands were not diseased. The colon was ulcerated; in the transverse and descending colon the ulcers were circular, a line or two in diameter, and most of them had dark bottoms.—Assistant Surgeon George M. McGill, U. S. A.

---

* Assistant Surgeon McGill was subsequently transferred to the Hicks hospital, Baltimore, Maryland, where he printed the accounts of twenty-three additional *post mortem* examinations. These, with the sixty-one referred to in the text, were bound under the title "Observation Book—*Ante-mortems* and *Post-mortems*." Of this little work its author says: "This book is only a printed note-book intended for the Surgeon-General's Office, and for the officers of National and Hicks hospitals, who have desired copies. Criticism upon it, therefore, would be wholly out of place." In using the material contained in this Observation Book, considerable condensation has been necessary, and some corrections of names and dates have been supplied by the register of the hospital.

CASE 196.—Private John E. Stover, company C, 62d New York volunteers; age 45; admitted from the army of the Potomac October 22, 1864. Chronic diarrhœa. [It appears from the list of wounded of the 3d Division, 6th Army Corps, that this man received a gunshot flesh wound of the right knee, May 5, 1864, during the battle of the Wilderness, Virginia. The register of the Emory hospital, Washington, D. C., shows that he was admitted for this wound May 17th, and returned to duty July 3d. It appears by the register of the Sheridan field hospital, Winchester, Virginia, that he was admitted to that hospital from the field hospital of the 2d Division, 6th Army Corps, September 30, 1864, suffering with diarrhœa, and sent to general hospital October 18th.] According to his own statement he had also suffered from intermittent fever. When admitted he had frequent slimy dejections, which were partially fæcal, but no chills. He was treated with quinia, tannin, and morphia, and improved at first, but the diarrhœa recurred at intervals, and various tonics and mineral astringents were tried without effect. He constantly complained of pain in the lower portion of the abdomen; his appetite was capricious; at times there was some mental aberration. Twenty-four hours before death he was attacked with convulsions. Died, February 24, 1865.—Acting Assistant Surgeon W. G. Smull. *Autopsy* six hours after death: Body much emaciated; rigor mortis slight. There were two ounces of fluid in the subarachnoid space; the brain weighed forty-two ounces, and was somewhat congested; on the floor of the fourth ventricle a reddish V-shaped discoloration was observed; the middle commissure of the brain was wanting. Both pleural sacs contained much serum. The left lung weighed eleven ounces; the posterior portion of its lower lobe was congested hypostatically. The right lung contained a calcareous nodule, but was otherwise healthy; it weighed eleven ounces. The surfaces of both lungs presented an excess of pigment. The heart weighed six ounces; the lining membranes of the pulmonary artery and of the aorta were reddened; there were no heart-clots; the pericardium contained a small quantity of serum. The liver was cirrhosed; it weighed twenty-seven ounces. The spleen was firm, pale externally, its capsule thickened; internally it was dark-violet, the trabeculæ distinct; it weighed four ounces. Pancreas reddish; weighed one ounce. The small intestine, and the greater portion of the large intestine, appeared to be normal. The sigmoid flexure and rectum were greatly thickened, the rectum being about four lines thick; in the sigmoid flexure the mucous membrane presented a white rough patch and a region of ulceration; one of the ulcers in the upper part of the sigmoid flexure penetrated to the muscular coat.* Kidneys normal; weighed three ounces and a half each. One of the suprarenal capsules was large, yellowish-white externally, dark cherry-colored internally.—Assistant Surgeon George M. McGill, U. S. A. [No. 616, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the colon, presenting follicular ulcers and superficial excavations.]

CASE 197.—Private John Atwater, company I, 44th Ohio volunteers; age 22; admitted from Annapolis, Maryland, March 11, 1865. Chronic diarrhœa. [This man appears on the register of the 1st division of the Annapolis hospital, Maryland, as admitted from Wilmington, North Carolina, March 8, 1865—acute pneumonia—sent to Baltimore March 11th. The diagnosis on the register of the National hospital, Baltimore, is typhoid fever.] He stated that his disease commenced about two months previously, while he was a prisoner of war. When admitted he was extremely feeble; his tongue red and glazed; the entire abdomen tender. His discharges were lienteric, the undigested food being mixed with a large quantity of sero-mucous fluid. Mineral and vegetable astringents, combined with tonics and stimulants, were tried without effect. Died, March 22d.—Acting Assistant Surgeon W. G. Smull. *Autopsy* forty-eight hours after death: Body greatly emaciated; some slight rigor mortis. The pia mater was moderately congested; on section of the brain substance the cerebral puncta appeared more numerous on the left side than on the right; the brain weighed forty-five ounces. The heart weighed eight ounces and a quarter; both sides contained white fibrinous clots, which, on the right side, extended into the pulmonary artery. The lower and posterior portions of the right lung contained a number of consolidated lobules—(lobular pneumonia?) the left lung was congested posteriorly, and ecchymosed spots were observed beneath the pleura of the lower lobe; the right lung weighed twenty-five ounces, the left seventeen ounces. The liver was friable, presented a marked nutmeg appearance, and weighed forty-eight ounces; the gall-bladder was filled with thick black bile. The spleen weighed seven ounces. The pancreas weighed four ounces. The stomach was congested; the lower part of the jejunum slate-colored. Peyer's patches were not diseased. The cæcum was congested. The solitary glands were enlarged, and marked with black pigment in the cæcum and ascending colon. In the transverse colon there were large irregular ulcers, which, as a rule, were found in the pouches of the colon. In the descending colon and rectum the ulceration had destroyed almost the whole surface of the mucous membrane, leaving many intact islets in the midst of the ulcerated tract, the whole, when viewed from a little distance, having the appearance of coarse granulations; the submucous and muscular coats of the ulcerated portions of the gut were much thickened. The mesenteric glands were slightly enlarged. The kidneys were light-colored, congested inferiorly; the right weighed five ounces and a quarter, the left four and a half.—Assistant Surgeon George M. McGill, U. S. A.

CASE 198.—Corporal John McEwart, company D, 7th New York volunteers; age 28; admitted from Annapolis, Maryland, March 11, 1865. Chronic diarrhœa, contracted while a prisoner of war. [The register of the 1st division of the Annapolis hospital, Maryland, shows that this man was admitted from Aiken's Landing February 25, 1865, with chronic diarrhœa, and sent to Baltimore March 10th.] When admitted he was pale and emaciated, pulse small and feeble, tongue white in the centre and red toward the edges; the abdomen was tender and somewhat painful; the stools were fluid, dark, and offensive, averaging ten or twelve a day; his appetite was good. Opium and acetate of lead, vegetable astringents and tonics, were fruitlessly prescribed. Died, March 24th.—Acting Assistant Surgeon J. G. Keller. *Autopsy* fourteen hours after death: Body greatly emaciated; rigor mortis slight. There was a considerable quantity of fluid in the subarachnoid space, and in the ventricles of the brain; numerous puncta vasculosa appeared on section of the cerebrum; the brain weighed forty-nine ounces. There were old pleuritic adhesions on both sides. The surface of both lungs was freely sprinkled with black pigment; the right lung was congested posteriorly, and on section of the lower lobe several ecchymosed spots were observed; the posterior part of the lower lobe of the left lung was in a state of red hepatization, and presented, superficially, several ecchymosed spots;

* Dr. McGill, in a note to this case, says of the rectum and sigmoid flexure: "The specimen was considered one of cancerous disease, although no microscopic examination was made of it." It is difficult to imagine what induced this notion.

the right lung weighed twenty ounces and a half, the left fifteen and a half. The heart weighed five ounces and six-eighths; there were fibrinous clots in both sides, extending into the aorta and pulmonary artery. The liver was firm, bronzed, and weighed twenty-eight ounces; the gall-bladder was filled with amber-colored bile. The spleen weighed three ounces and a half. The pancreas weighed seven ounces [?]. The stomach was slightly congested. There were regions of congestion in the jejunum and ileum. In the colon were a number of round and oval ulcers, which penetrated to the submucous tissue; between the ulcers the mucous membrane was dark-slate colored. The kidneys weighed four ounces each. The suprarenal capsules were large and light-colored.—Assistant Surgeon George M. McGill, U. S. A.

CASE 199.—Private Abram J. Stokes, company C, 120th New York volunteers; age 23; admitted February 21, 1865. Consumption. [The records of the depot field hospital, 2d Army Corps, show that this man was admitted February 2, 1865—diagnosis, inflammation of the lungs—sent to general hospital February 20th.] When admitted he was considerably emaciated; cheeks suffused with a hectic flush, eyes prominent, conjunctivæ injected. He coughed almost incessantly, and was slightly hoarse; complained but little of pain in the chest; had but little appetite, and after taking food frequently ejected it during a fit of coughing. Colliquative diarrhœa and night-sweats persisted during the case. Died, March 23d.—Acting Assistant Surgeon W. G. Smull. *Autopsy* thirty-six hours after death: Body not much emaciated; no rigor mortis. The pia mater was somewhat congested; but little fluid was found in the subarachnoid space; there was a small quantity of limpid serum in both lateral ventricles; on section of the cerebrum numerous puncta vasculosa were observed; the right side of the floor of the fourth ventricle presented some arborescent congestion; the substance of the cerebellum was softer than that of the cerebrum; the brain weighed forty-nine ounces. The right lung was congested, contained miliary tubercles, and had a vomica posteriorly in its upper part; its lobes were united by adhesions; the pleura covering it was irregularly thickened; the left lung was coated with lymph, its lobes interadherent; its upper lobe contained an immense number of miliary tubercles; the right lung weighed forty ounces, the left thirty-three ounces. The heart was flabby, and weighed fifteen ounces and a quarter; its right side contained a large white clot, the left side mixed clots. The liver weighed sixty-three ounces, and was of a light-red color; the gall-bladder was filled with black bile. The spleen weighed six ounces and a quarter; there were some minute bodies resembling tubercles on the dorsum of the organ. The pancreas weighed three ounces and five-eighths. Some ecchymosis was observed in the fundus of the stomach. White bodies resembling tubercles were found in Peyer's patches. The mucous membrane of the large intestine presented regions of hyperæmia, between which the mucous membrane was slate-colored. The kidneys were flabby and light-colored; the left weighed seven ounces and a quarter, the right five and a quarter. The suprarenal capsules were somewhat dark in color, but apparently healthy.—Assistant Surgeon George M. McGill, U. S. A.

The six following cases are from the HICK'S HOSPITAL, Baltimore, Maryland, Surgeon Thomas Sim, U. S. V., in charge. The autopsies were made by Assistant Surgeon George M. McGill, U. S. A., and were reported in his "Observation Book." See note, page 125:

CASE 200.—Private John Hillman, company E, 28th Indiana volunteers; admitted August 6, 1865. Chronic diarrhœa. [The diagnosis on the register is typhoid fever.] At the date of admission this man had from thirty to forty stools a day, with involuntary evacuations during sleep; pulse frequent; tongue dry. Died, August 8th. *Autopsy* twelve hours after death: Body but slightly emaciated; rigor mortis great. The pia mater was congested; there were several small stellate spots resembling extravasations of blood on the floor of the fourth ventricle; the brain weighed fifty-five ounces. The heart was flabby and of a blood-red color; it weighed nine ounces and a half; there was a white clot in the right side, which extended into the pulmonary artery; there was slight atheroma of the aorta, and some induration of the attachments of the aortic valves. Both lungs were congested posteriorly, and presented in the congested portion a few consolidated lobules; on the right side several of the consolidated lobules were infiltrated with a purulent fluid; the left lung weighed twenty-five ounces, the right twenty ounces. The liver weighed sixty-four ounces; the gall-bladder was filled with black bile. The spleen weighed six ounces. The kidneys weighed five ounces each. The suprarenal capsules were normal. The omentum was thickened and adherent to the intestines. The opposed surfaces of the knuckles of intestine generally were agglutinated with lymph. The mucous membrane of the stomach was congested, especially in the fundus. The duodenum and upper portion of the jejunum were ash-colored and flabby; the lower portion of the jejunum was congested, and presented deep transverse ulcers parallel to the valvulæ conniventes and between them; these ulcers invaded the muscular coat; their sites were indicated externally by peritoneal opacity and adhesions; although generally between the valvulæ conniventes, they sometimes extended over them, and sometimes penetrated through them so as to leave bridges of mucous membrane; in the lowest part of the jejunum, and in the ileum, the ulcers were oval; a greenish-yellow lymph adhered to some of them. The mucous membrane of the large intestine was hyperæmic in regions, and in the sigmoid flexure frosted with minute granules of lymph, which firmly adhered to the congested mucous surface.—Assistant Surgeon George M. McGill, U. S. A.

CASE 201.—Private Reuben Collins, company E, 45th United States colored troops; admitted from McKim's Mansion hospital July 24, 1865. Debility. [This man appears on the register of McKim's Mansion hospital, Baltimore, Maryland, as admitted from field hospital June 26, 1865, with chronic peritonitis.] He was feeble and emaciated; his mind obtuse, bowels loose, abdomen tender. Died, August 15th. *Autopsy* six hours after death: The substance of the brain was soft; a quantity of reddish fluid was found in the left lateral ventricle; in the left choroid plexus, about an inch from the foramen of Monro, was a mass of white granular caseous material resembling tubercle; the brain weighed forty-two ounces. The right lung weighed twenty-one ounces, the left twenty-four ounces; no tubercles in either. The bronchial glands were enlarged and dark. The heart was normal; both auricles contained dark clots; in the ventricles there were small white clots, which extended into the aorta and the pulmonary artery. Old peritoneal adhesions connected the liver to the abdominal parietes; on section the liver was dark-red, and contained a large number of saccules, which varied from the size of a grape-seed to that of a bean, and

contained a semi-fluid granular matter. The liver weighed fifty ounces. The spleen weighed four ounces; it was firm, dark-colored, and contained a single deposit of tubercle of some size. Both kidneys contained tubercles; the right weighed five ounces, the left four ounces and a half. Two ulcers were observed in the ileum. In the ascending colon and the sigmoid flexure there were a moderate number of oval, deep, irregular ulcers. The intestinal walls were readily torn. The greater omentum was thickened and studded with tubercles.—Assistant Surgeon George M. McGill, U. S. A.

CASE 202.—Private Henry Beyer, company K, 1st Maryland volunteers; a discharged soldier; admitted from Jarvis hospital July 26, 1865. Typhoid fever (?), followed by chronic diarrhœa. He became much emaciated, and about ten days before his death pus was observed in the anterior chamber of the right eye. Died, August 22d. *Autopsy:* Body emaciated; no rigor mortis; suggillation posteriorly. Pia mater congested; commissura mollis absent; the brain weighed fifty ounces and one-eighth. The posterior portion of the upper lobe of the right lung was in a state of gray hepatization, the lower lobe congested; there was a group of consolidated lobules in the anterior portion of the upper lobe of the left lung; the posterior portion of the lower lobe was semi-solidified and ecchymosed; the right lung weighed twenty-one ounces, the left eighteen ounces. The heart weighed eight ounces; there was a white clot in its right side, a black one in its left. The liver was of normal consistence, full of blood, and weighed fifty-six ounces; the gall-bladder contained about three ounces of yellowish bile. The spleen weighed six ounces and a half; the pancreas one ounce. The kidneys were rather soft; the right weighed eight ounces. the left six ounces. The suprarenal capsules were small. The stomach was large and much discolored. The jejunum discolored with bile. The large intestine thin; its mucous membrane in regions was congested and of a rich purple color.—Assistant Surgeon George M. McGill, U. S. A.

CASE 203.—Private John Brooks, company A, 146th Indiana volunteers; admitted August 12, 1865. Acute dysentery. This man was on duty in the guard of the hospital when taken sick. When admitted he had frequent discharges from the bowels, and bilious vomiting; pulse 108 and full; tongue coated in the centre. He complained of pain in the epigastric region, especially after vomiting. August 19th: The discharges are bloody and very frequent; hiccough is very troublesome. August 28th: Had a profuse hæmorrhage from the bowels last night. August 30th: The patient is comatose, the stools black, offensive, and passed involuntarily. Treatment: Counter-irritation to the abdomen, alteratives and anodynes, lead and opium, stimulants; during the last ten days large doses of opium and astringent enemata. Died, September 1st. *Autopsy* twenty hours after death: Body not much emaciated; rigor mortis slight. There was some congestion of the pia mater posteriorly; the brain apparently normal; it weighed forty seven ounces. The heart was flabby, and weighed nine ounces and three-quarters. The right lung weighed thirteen ounces; its lower lobe was congested posteriorly; the left lung was normal; it weighed fourteen ounces. The liver weighed sixty-four ounces; numerous little yellowish-white nodules were scattered through its substance, the largest about the size of peas. The spleen was firm, and weighed seven ounces and a half. The pancreas weighed two ounces and a half. The right kidney weighed five ounces and a half, the left seven and a half. The intestines were ash-colored externally. The mucous membrane of the stomach was discolored in patches. The patches of Peyer presented the "shaved-chin" appearance. In the upper part of the ileum a granular matter adhered to the valvulæ conniventes; in some places it was pale, in some brownish; lower down, light-colored patches, resembling superficial ulcers, were associated with the Peyer's patches; just above the ileo-cæcal valve the ileum was honeycombed by a large number of ulcers, which penetrated to the muscular coat. Throughout the large intestine there were many deep ulcers, between which the mucous membrane was of a deep cherry-red color. The coats of the intestine were readily torn.—Assistant Surgeon George M. McGill, U. S. A.

CASE 204.—Private John Whalen, company G, 3d New York volunteers; age 30; admitted August 31, 1865. Dysentery of about four days' duration. According to the statement of the patient, he was taken sick while with his regiment on its way from Raleigh, North Carolina, to New York. When the regiment reached Baltimore he was sent to hospital, having taken no remedies before his admission. He had considerable symptomatic fever when admitted; the tongue was thickly coated with a light-brown fur; there were dark sordes on the teeth; the stools were watery, dark-colored, mixed with blood, and had a highly offensive and sickening odor; the abdomen was tender, and there was severe tenesmus. The day after admission the fever subsided, and the extremities became cold. He was delirious at night, especially on the alternate nights. Treatment: When first admitted a dose of castor oil and laudanum was given; subsequently tannic acid and opium, injections of acetate of lead, and acetate of morphia, &c. Stimulants were administered freely. Died, September 6th. *Autopsy:* Muscles well developed; rigor mortis marked. Pia mater injected; brain-substance normal; the brain weighed forty-nine ounces. Pleuritic adhesions existed on both sides. There was some deposit of tubercle in the upper portion of each lung; in the left lung the tuberculous masses were of considerable size, and the lung-tissue surrounding them was solidified; the tubercular deposit was firm, and no cavities had formed; both lungs contained much black pigment; the right lung weighed twelve ounces and a half, the left fourteen ounces. The heart weighed ten ounces and a half; white clots were found in both sides. The liver weighed eighty-six ounces; on section it was light-colored; on the upper surface of the left lobe were two depressions resembling cicatrices. The spleen was firm, and weighed seven ounces. The pancreas weighed three ounces and a half. The right kidney weighed five ounces, the left six ounces. The suprarenal capsules were large. The mucous membrane of the stomach was congested and of a scarlet color. The jejunum contained a yellowish, viscid, jelly-like substance, which became dark-colored lower down; in the lower part of the jejunum and upper part of the ileum the mucous membrane was of a dark purple; lower down were numerous minute, circular, superficial ulcers, to which a light-gray pseudomembrane adhered. The large intestine was thickened and coated with greenish-yellow pseudomembrane from the cæcum to the rectum; at points where this layer was deficient the mucous membrane was dark purple.—Assistant Surgeon George M. McGill, U. S. A.

CASE 205.—Private Michael Mulvey, company H, 2d Massachusetts heavy artillery; admitted September 10, 1865. Chronic diarrhœa. The patient stated that he had suffered from an attack of fever, from which he had convalesced very slowly; subsequently he was attacked with dysentery. He was somewhat emaciated, pulse quick, appetite poor; had five to ten bloody stools daily. September 15th: He complained of violent pain in the abdomen. Treatment: Anodynes, astringents, stimulants,

milk diet. Died, September 22d. *Autopsy* ten hours after death: Body emaciated; rigor mortis decided. The brain weighed three pounds; its substance was firm; some congestion of the floor of the fourth ventricle was observed; there was a considerable quantity of subarachnoid fluid. There were numerous old pleuritic adhesions on the right side. The lobes of the left lung were interadherent and the upper lobe adhered to the thoracic parietes; a number of ecchymosed spots were observed on the surface of the right lung and the upper lobe of the left; the right lung had but two lobes, and contained a single white cheesy nodule near its apex; the right lung weighed sixteen ounces, the left eleven ounces. The bronchial glands contained much black pigment, but were of normal size. The heart weighed nine ounces and a half; there was a white clot in its right side, a black one in the left. The liver contained a considerable number of metastatic foci, many of which had softened into a purulold liquid; it weighed sixty ounces and a half; the gall-bladder contained some greenish bile. The spleen weighed fifteen ounces. The jejunum was congested in regions; about half way down the ileum, transverse ulcers made their appearance, situated on the side of the mesenteric attachment; these became more numerous and deeper lower down, and were associated with thickening of the intestinal wall. The large intestine was extensively ulcerated, the ulcers being largest and deepest in the descending colon. The right kidney weighed five ounces, the left six ounces. The suprarenal capsules weighed three-quarters of an ounce each.—Assistant Surgeon George M. McGill, U. S. A.

The following case was forwarded on a descriptive list from McKim's Mansion Hospital, Surgeon S. D. Freeman, U. S. V., in charge:

Case 206.—Private Edwin Powers, company H, 7th Indiana volunteers; aged 23; admitted August 27, 1863. Dysentery. This man was attacked with dysentery while at Camp Bradford, Maryland, some three weeks previously. The camp was at the time notorious for its filthy condition. When admitted he was extremely emaciated, his eyes sunken, conjunctivæ congested; he complained of supraorbital pain; his tongue was coated, his throat dry; the evacuations averaged six daily; the extremities were cold; pulse quick but weak. Treatment: Pills of nitrate of silver and opium; beef-essence and milk-punch. August 30th: Add three grains of sulphate of quinia three times daily. August 31st: Had four or five stools during the night; vomited in the morning after eating; the abdomen is tender on pressure. September 2d, 9 A. M.: Pulse 120; tongue coated; skin hot; bowels moved only once since yesterday. 5 P. M.: Singultus and vomiting; refuses everything but milk-punch; the passages are involuntary. Died, September 3d. *Autopsy* three hours after death: An ulcer of the cornea was observed in each eye. The ileum was lined with a greenish secretion, and appeared slightly inflamed just above the ileo-cæcal valve. The descending colon was inflamed, and coated with a yellowish diphtheritic deposit. The rectum was of a very dark color, and ulcerated near the anus. The kidneys were enlarged; one of them weighed seven ounces.—Medical Cadet C. W. L. Bradley.

The histories of the six following cases are from the case-book of the Jarvis Hospital, Baltimore, Maryland, Assistant Surgeon DeWitt C. Peters, U. S. A., in charge. The autopsies were made by Acting Assistant Surgeon B. B. Miles:

Case 207.—Private Rufus A. Egerton, company F, 1st Vermont cavalry; a paroled prisoner; age 26; admitted September 16, 1863. Chronic diarrhœa. Died, November 4th.—Acting Assistant Surgeon B. B. Miles. [No. 227, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the colon, which is somewhat thickened, and presents a number of follicular ulcers, some of which have extended into irregular jagged excavations.]

Case 208.—Private Gilbert F. Sherwood, company K, 144th New York volunteers; admitted July 20, 1863. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 12th New York volunteers, Warrenton Junction, Virginia, as having been under treatment for diarrhœa during the early part of the month of July, and sent to general hospital July 11th.] About August 1st his case assumed a typhoid type, and a low delirium set in, which was somewhat relieved by a large fly-blister over the epigastrium, and ice to eat or suck constantly. In the treatment of the diarrhœa Hope's camphor mixture and muriatic acid were used in conjunction with tonics, quinia, beef-tea, barley-water, &c. Died, August 21st.—Acting Assistant Surgeon F. Hinkle. *Autopsy* twelve hours after death: The mucous membrane of the whole intestine was inflamed, especially in the caput coli and the last twenty inches of the ileum; it presented a deep-red velvety appearance, with many small ulcers.—Acting Assistant Surgeon B. B. Miles. [No. 76, Medical Section, Army Medical Museum, is from this case. The specimen consists of the last four inches of the ileum and a part of the cæcum; the ileum is thickened and ulcerated; the ulcers, about twenty in number, extend through the submucous connective tissue to the muscular coat; they vary from one to eight lines in long diameter, their edges rounded, thickened, and overhanging. In the cæcum there are a number of small follicular ulcers.]

Case 209.—Private William Hughes, company E, 29th Missouri volunteers; age 30; a paroled prisoner; admitted from Richmond, Virginia, April 18, 1864. Chronic diarrhœa. Died, May 9th. *Autopsy* twenty-four hours after death: The whole of the right lung was hepatized and everywhere adherent to the thoracic parietes; the left lung was very much congested, partly hepatized, and presented slight pleuritic adhesions. The heart was pale and flabby. There was about a quart of pus in the peritoneal cavity. The intestines were extensively congested. The spleen was soft. The kidneys were large and congested.—Acting Assistant Surgeon B. B. Miles.

Case 210.—Private G. R. Everts, company G, 2d East Tennessee volunteers; paroled prisoner; age 22; admitted from Richmond, Virginia, April 18, 1864. Diarrhœa and starvation. Died, May 3d. *Autopsy* twenty-four hours after death: A large cavity was found in the middle lobe of the left lung. There were two quarts of serum in the left pleura, pushing the heart to the right side. There was also a cavity in the middle lobe of the right lung; the upper lobe was consolidated by deposition

of tuberculous matter. The right lung was everywhere bound to the thoracic parietes by pleuritic adhesions. The heart was flabby and pale, but normal in size; the aortic valves were thickened. The spleen was soft and friable. The gall-bladder was empty. There was general peritonitis, with effusion of pasty lymph, involving especially the lower part of the ileum and the caput coli. The solitary follicles of the small intestine were ulcerated. The lower part of the ileum was gangrenous (?) and the whole of the rectum was in the same condition. Acting Assistant Surgeon B. B. Miles. [Nos. 307 and 308, Medical Section, Army Medical Museum, are from this case. The specimens are successive portions of the ileum, with well-marked valvulæ conniventes. Peyer's patches and some of the solitary follicles are ulcerated. The peritoneal surfaces of both pieces are coated with croupous lymph.]

CASE 211.—Private James Turvey, company C, 14th Kentucky volunteers; age 21; admitted from general hospital, Annapolis, Maryland, November 28, 1864. Chronic diarrhœa. [This man appears on the register of the hospital steamer Atlantic as admitted November 20th; sent to Annapolis November 25th. He is borne on the register of the 1st division of the Annapolis hospital as admitted from Savannah, Georgia, November 25th, and sent to Baltimore November 27th. No diagnosis is recorded in either register.] Died, December 19th. *Autopsy* twenty-four hours after death: The lungs and heart were normal. The liver was very much congested, and the gall-bladder largely distended with bile. The spleen was large and congested. The transverse colon was everywhere adherent to the peritoneum; at the upper part it was perforated, and fæcal matter had been discharged into the abdominal cavity, inducing gangrenous peritonitis. About four ounces of fluid were found in the peritoneal cavity. The mucous membrane of the whole colon was extensively ulcerated.—Acting Assistant Surgeon B. B. Miles.

CASE 212.—Private Horatio G. Perkins, company D, 2d Connecticut heavy artillery; age 27; admitted from general hospital, Winchester, Virginia, November 5, 1864. Chronic diarrhœa. [This man appears on the register of the field hospital of the 1st Division, 6th Corps, as admitted October 24th—remittent fever—and sent to general hospital November 3d. He is borne on the register of the Sheridan depot field hospital, Winchester, Virginia, as admitted November 3d—chronic diarrhœa—and sent to general hospital November 4th.] Died, January 9, 1865. *Autopsy* twenty-four hours after death: The upper lobe of the right lung was adherent to the costal pleura, and contained a large tuberculous cavity with irregular edges; the whole lung was infiltrated with tuberculous matter; the left lung was normal. The cavities of the heart were filled with fibrinous clots. The intestines were much contracted, and in different parts considerably congested, but no ulcerations could be found. The mesenteric glands were enlarged and filled with tuberculous matter. The liver and spleen were normal. Both kidneys presented evidences of fatty degeneration, and were much hypertrophied.—Acting Assistant Surgeon B. B. Miles.

The three following cases were forwarded on medical descriptive lists from PATTERSON PARK HOSPITAL, Baltimore, Maryland, Surgeon Thomas Sim, U. S. V., in charge:

CASE 213.—Private William Keighley, company A, 29th Maine volunteers; age 43; admitted August 1, 1864. Dysentery. [This man appears on the register of the general hospital, Frederick, Maryland, as admitted from the field July 30, 1864—hæmorrhoids—sent to Baltimore August 1st.] The patient was a man of intemperate habits, and was considerably emaciated. Pills of acetate of lead and opium were prescribed at first; subsequently pills of blue mass, opium and ipecacuanha, and pills of quinine, opium and ipecacuanha. Diet: Milk, vegetable soup, and stimulants. August 10th: He passed about twenty feet of tape-worm, after which he appeared easier. August 20th: From the renewal of the symptoms it was suspected that a considerable length of the tape-worm still remained, or that perhaps a perforation of the intestines had taken place. Died, August 25th. *Autopsy:* The colon was extensively inflamed and ulcerated. In the ascending colon two perforations were found. No remaining portions of the tape-worm could be discovered.—Acting Assistant Surgeon P. S. Kinnerman.

CASE 214.—Private J. N. Keeton, company D, 2d Virginia cavalry; age 19; admitted October 25, 1864. Chronic dysentery. [This man appears on the register of the Sheridan depot field hospital, Winchester, Virginia, admitted from the field October 9, 1864—debility—sent to general hospital October 10th.] The patient stated that he had been sick with dysentery some two or three weeks; also, that he had an attack of the same disease six or eight months previously, from which he never entirely recovered. His passages are still slimy and bloody. ℞. Castor oil two ounces, tincture of opium two drachms. Take a teaspoonful every three hours. October 27th: Is not much improved, but his passages are less frequent; he has had only four during the last twenty-four hours. He is certain that he will not recover, and is very melancholy. Ordered injections of starch-water and laudanum. October 30th: There has been no improvement. ℞. Dover's powder eighteen grains, blue pill ten grains; make nine pills. Take one every four hours. November 5th: To take quarter of a grain of opium in pill three times a day; low diet. November 18th: Seems about the same; has a little more appetite. To take ten drops of chlorodyne every four hours; half diet. December 8th: The patient seemed to improve for a time while taking the chlorodyne, but it has now lost its effect, and he is as ill as before taking it. ℞. Subcarbonate of bismuth half a drachm, Dover's powder ten grains, white sugar half a drachm; make twelve powders. Take one three times a day. January 10, 1865: There has not been much change. Sometimes the bowels are checked for two or three days, when he always complains of great abdominal pain; then the passages of blood and mucus return as before. He begs for anodynes constantly. January 21st: Renewed the injections of laudanum and starch. February 16th: No better. Apply a blister, five inches square, to the surface of the abdomen. March 6th: The patient, who has thus far been able to sit up a while nearly every day, now says he has not strength enough to do so; nevertheless, he gets up on the vessel when necessary. He constantly complains of pain in the bowels and wants anodynes. To take the third of a grain of opium four times daily. Died, March 15th. The symptoms had continued without much change until a few hours before death, when his countenance became very pallid, and consciousness departed. *Autopsy* eighteen hours after death: No rigor mortis. The lower portion of the ileum was congested. The mucous membrane of the colon was thickened and of a very dark-blue color, except about six inches of the descending colon, which were ulcerated. All the other viscera were normal.—Acting Assistant Surgeon Geo. W. Fay.

CASE 215.—Private James Martin, company E, 28th Massachusetts volunteers; age 18; admitted February 8, 1865, from City Point, Virginia. Chronic diarrhœa. [This man appears on the register of the hospital of the 1st Division, 2d Army Corps, as having been treated for acute diarrhœa during January, 1865, and sent to general hospital February 1st. He appears on the register of the depot field hospital, 2d Army Corps, City Point, Virginia, admitted February 2d—chronic diarrhœa—sent to general hospital February 6th, per steamer State of Maine.] When admitted he was extremely emaciated, the fæcal discharges occurring frequently and involuntarily; he was not expected to live through the day. To take a tablespoonful of brandy every two hours; hot water to feet. ℞. Chalk mixture one ounce, tincture of catechu and extract of hæmatoxylon of each one drachm. To take a teaspoonful of the mixture every four hours. February 10th: He seems easier, but the fæcal discharges are still frequent and involuntary. ℞. Brandy-toddy four ounces. Take a tablespoonful every four hours. February 14th: The patient seems to have more strength, but the diarrhœa is no better. ℞. Subnitrate of bismuth thirty grains; in three powders. Take one every four hours. Continue the brandy-toddy. February 16th: Is failing; discharges very frequent. ℞. Tannic acid sixteen grains, powdered opium two grains; make four powders. Take one every four hours; also a tablespoonful of brandy-toddy every two hours. Died, February 20th. *Autopsy:* The small intestine was very much congested throughout its entire length. The entire colon was disorganized by ulceration and sloughing, the external coat alone seeming to hold it together; at the junction of the transverse and descending colon there was a large perforation. No abdominal tenderness had been observed during life.—Acting Assistant Surgeon W. Kempster.

The next five cases were reported on medical descriptive lists from the first division of the ANNAPOLIS HOSPITAL, Maryland, Surgeon Bernard A. Vanderkieft, U. S. V., in charge:

CASE 216.—Private John B. Stever, company D, 116th Illinois volunteers; age 30; admitted August 22, 1863. Dysentery. This patient was first seen by the reporter September 9th. He was then suffering with dysentery. He had frequent desire to go to stool, with great straining, small evacuations, and complained of soreness at the anus; was very much debilitated and emaciated, nevertheless his appetite was remarkably good. The stools were light-yellow, flocculent, and mixed with blood and mucus; they had a fetid odor. To take five grains of subnitrate of bismuth and a quarter of a grain of calomel three times a day. Beef-tea, rice-jelly. September 14th: The disease continues unchecked. To take every four hours a pill containing quarter of a grain of nitrate of silver, half a grain of opium, and two grains of quinine. September 21st: Seems to be improving slowly. To take pills of quinine and morphia, injections of tannic acid in starch-water, and twice daily a raw egg with brandy. October 1st: Seems very much better; had but two stools in the last twenty-four hours, and these apparently more natural. Continued treatment. October 25th: Still improving; is able to sit up; appetite good. To take pills of nitrate of silver, quinine, and opium; beef-steak. October 26th: Has an attack of double pneumonia; expectoration viscid and rusty; considerable crepitation and dulness over both lungs; much cough; pulse small, 110; skin hot. ℞. Tartrate of antimony and potassa two grains, water two ounces. Take a teaspoonful every hour. Beef-tea, Irish-moss jelly, flaxseed tea. October 28th: Complete flatness on percussion; very little expansion of the lungs; is so much debilitated that he has no power to expectorate; no heat of skin; pulse 90 and feeble. Stop the antimonial. Apply a blister, six inches by ten, to the chest. Half a grain of calomel and one-sixth of a grain of ipecacuanha every two hours. Brandy and egg. October 31st: Sinking very rapidly; takes no nourishment; pulse intermittent; involuntary evacuations. Died, November 1st. *Autopsy* sixteen hours after death: Both lungs were hepatized and softened, the right being much softer than the left. The heart was very small; its walls thin. The liver, spleen, and kidneys were normal. The stomach was very much distended with mucus, and contained some pus. The intestines were inflamed; the large intestine was considerably ulcerated and thickened.—Acting Assistant Surgeon J. M. Longnecker.

CASE 217.—Private James E. Griffing, company D, 127th New York volunteers; age 20; admitted October 29, 1863. Pleuro-pneumonia. This man was captured near Goose Creek, Virginia, July 21, 1863; sent to Belle Isle, Virginia, arriving there July 25th. Was badly treated; lay out in the rain and dew for three weeks on sand which was full of vermin; had only a coat, shirt, and pants for protection; was barefooted the whole time. Became worn down by diarrhœa, and when admitted to this hospital was very much emaciated and full of vermin. He had severe diarrhœa, a bad cough, and complained of a sharp pain in the left side; could not draw a long breath; his tongue was red and glazed. There was dulness on percussion over most of the left and part of the right lung; bronchial respiration, with some friction sound, was heard. Ordered warm mustard foot-baths; sinapisms to the left side over the seat of pain; a cough mixture, milk-punch, extra diet. October 31st: Says he feels much better; pain nearly gone; diarrhœa not quite so bad. Continued treatment. November 1st: The pain in the left side is worse again; respiration difficult; bowels quite loose; pulse feeble; tongue red. Physical signs as when admitted. Repeat mustard to side and cough mixture; also to take two grains and a half of Dover's powder and two of acetate of lead every four hours. November 3d: The pain is easier, but the bowels very loose; the patient is very feeble. Continue treatment. November 4th: Use the following as an injection: ℞. Starch-water one ounce, sulphate of morphia three-eighths of a grain, sulphate of quinia five grains. November 5th: He had but one passage since yesterday morning; the other symptoms are the same. Discontinue the injections. November 7th: Is much weaker; can scarcely speak; pain in the chest more severe; coughs feebly; respiration difficult; pulse 90; had four stools during the night. Died at 11 A. M. *Autopsy* twenty-seven hours after death: Almost the whole of the left lung was solidified; its surface was coated with lymph, and there were four ounces of serum in the pleural sac; the right lung was congested. The heart was very small. The liver was normal. The stomach small. The intestines were contracted. The lower portion of the ileum and most of the colon were much congested. No adipose tissue was observed, and the muscles of the body were pale and soft.—Acting Assistant Surgeon S. J. Radcliffe.

CASE 218.—Private Alfred Davis, company L, 6th Michigan cavalry; admitted from Richmond, Virginia, March 9, 1864. Chronic diarrhœa. This soldier was captured near Hagerstown, Maryland, July 12, 1863, and was held a prisoner of war by the enemy until March 7, 1864, when he was paroled, arriving here on the 9th. He stated that he was sick during the greater

portion of his imprisonment. He was excessively reduced, hardly more than a skeleton, and so weak he had to be carried from the boat to bed upon a stretcher. He had an exhausting diarrhœa, twelve stools in the last twenty-four hours, which were not painful, but he complains of constant pain in the back and lower extremities; the tongue was moist and clean; the pulse frequent and feeble; no appetite. ℞. Sulphate of quinia one scruple, sulphate of morphia one grain, dilute sulphuric acid two drachms, water five ounces. Take a tablespoonful every four hours; beef-tea and wine. March 12th: Condition much the same; the system does not respond to stimulants or medicines; pulse 120 and weak; there is slight tenderness in the right iliac region. Applied a mustard plaster to the abdomen. ℞. Ipecacuanha and opium, of each four grains, calomel three grains; make sixteen pills. Take one every four hours. March 14th: At the morning visit the condition of the patient was about the same. At the evening visit, 9 o'clock P. M., he was almost pulseless. Brandy and beef-tea were ordered to be taken alternately every hour. He died at 10 A. M. on the 15th. *Autopsy:* Body excessively emaciated; no rigor mortis. There were old pleuritic adhesions on the left side of the chest. The lungs were collapsed. The heart presented no abnormal appearance. The jejunum and ileum were much congested. The colon and rectum were thickened, and presented other evidences of chronic disease. The kidneys were healthy. Nearly all the tissues were unusually pallid.—Assistant Surgeon William S. Ely, U. S. V.

CASE 219.—Private David Smith, company B, 46th Ohio volunteers; age 36; admitted from Richmond, Virginia, March 9, 1864. Chronic diarrhœa. This man was taken prisoner July 26, 1863, near Jackson, Mississippi, and held until March 7, 1864, when he was paroled, reaching Annapolis on the 9th. He has suffered exceedingly during his lengthened imprisonment, and comes to hospital much reduced, anæmic, and laboring under chronic diarrhœa of a severe type. Tongue deep-red; appetite poor; stools mucous and watery, averaging twelve a day; pulse 100 per minute, small and wiry. To take turpentine emulsion every four hours. March 15th: The countenance and complexion have acquired an icteroid hue, and there is tenderness on strong pressure in the right iliac region. ℞. Mercury with chalk eighteen grains, Dover's powder twenty grains, sulphate of quinia twelve grains; make six powders. Take one every four hours, alternating with the turpentine mixture previously ordered; brandy as required. Turpentine stupes to abdomen. March 17th, P. M.: Is evidently failing; stools every hour or two; pulse hardly perceptible and very compressible. Stop former medicines; give quinine, beef-essence, and brandy both by the mouth and by injection. March 18th: The stools are passed involuntarily. Died, March 19th. *Autopsy* thirty-six hours after death: Rigor mortis marked. Both lungs were strongly adherent throughout nearly their entire extent. The stomach contained a pint of bilious-looking fluid. The jejunum and ileum were congested in many places. The colon and rectum were much thickened, and studded with numerous ulcerations, some of which had almost perforated.—Assistant Surgeon William S. Ely, U. S. V.

CASE 220.—Corporal Samuel Williams, company C, 11th Tennessee mounted infantry; age 31; admitted March 26, 1864. Chronic diarrhœa. The patient was a prisoner who arrived two days previously, in a very prostrate condition. His pulse was above 100, and so feeble that it could hardly be felt. He had over twenty loose discharges a day. To use enemata of starch and laudanum, and have four ounces of whiskey daily. March 29th: The diarrhœa has been a little better, but has become worse this morning. The discharges have a very fetid odor, and are tinged with blood. The pulse is somewhat stronger. Continue treatment. March 30th: Is still worse; the diarrhœa continues unchecked; the pulse is accelerated to 125; he has no appetite; complains of headache and great pain in the bowels. ℞. Acetate of lead two grains, sulphate of morphia one grain, sugar one drachm; make eight powders. Take one every four hours. April 3d: The patient is inclined to coma; passes his fæces involuntarily; the pulse is dicrotous and very weak, 125 per minute. Treatment continued. Died comatose, April 4th. *Autopsy:* The thoracic viscera presented nothing abnormal. The large intestine, especially about the sigmoid portion, was the seat of ulcers of every shape and size; some of them had penetrated through the muscular coat to the peritoneum.—Acting Assistant Surgeon H. Lowenthal.

The following case was reported on a medical descriptive list from the second division of the ANNAPOLIS HOSPITAL, Assistant Surgeon G. B. Parker, U. S. V., in charge:

CASE 221.—Private John W. Farrow, Company D, 4th Tennessee volunteers; age 22; admitted from Richmond, Virginia, March 30, 1864. Chronic diarrhœa. This man had been for two or three weeks a prisoner on Belle Isle, and was there attacked with diarrhœa. His alvine discharges were very frequent and watery; he had great thirst and but little appetite; his pulse was 110 and small; there was great tenderness in the whole course of the colon, and violent tenesmus. To take camphor and opium pills; milk and beef-tea. April 1st: Substitute five drops of nitric acid three times daily. April 4th: Use enemata of sulphate of zinc and laudanum in starch-water, with half a grain of morphia at bed-time. April 9th: Up to this date there has been but little abatement of his symptoms. He has complained of tenesmus and pain in the bowels, with frequent stools, which, however, contained no true fæcal matter. Substitute pills of nitrate of silver for the former treatment. Continue the morphia at bed-time. April 13th: To take half an ounce of castor oil and five drops of spirits of turpentine at a dose, and repeat in three hours; this to be followed by lead and opium pills. Died, April 17th. *Autopsy* fourteen hours after death: Extensive peritoneal adhesions bound the viscera to the abdominal walls, but there was no effusion of fluid into the peritoneal sac. The whole intestinal tube was in an almost gangrenous condition. The colon was extensively ulcerated, the ulceration extending into the rectum.—Acting Assistant Surgeon B. F. Berkley.

The next four cases were reported on medical descriptive lists from the ANNAPOLIS JUNCTION HOSPITAL, Maryland, Assistant Surgeon Cyrus Bacon, Jr., U. S. A., in charge:

CASE 222.—Private D. C. Stinecypher, company B, 2d East Tennessee mounted infantry; age 24; admitted June 7, 1864. Chronic diarrhœa and scurvy. This man was captured at Rogersville, Tennessee, November 6, 1863. He was

confined at Belle Isle, Virginia, seven months; was in hospital while there some six weeks. April 29, 1864, he was paroled, and arrived at Annapolis, Maryland, May 2d. [The register of the first division, Annapolis hospital, reports him admitted May 2d—consumption—transferred to Annapolis Junction June 7th.] When first seen by the reporter, June 21st, he had, besides his diarrhœa, evident effusion into the chest, pericardium, and abdominal cavity. The act of respiration was exceedingly laborious, and he could only lie on his right side, breathing even then with great difficulty. His face, left arm, and hand were greatly swollen, but he could use the arm freely; his appetite was craving. Ordered a combination of cream of tartar and squill as a diuretic, together with the free use of lemonade, good diet, and milk-punch. June 26th: The effusion is decreasing; there is less dyspnœa, but the pulse is small and very rapid, and the action of the heart irregular. June 27th: He complains of pain on pressure over the lumbar region, and is growing sensibly weaker; his appetite is decreasing. Stop the bitartrate of potassa and squill, which seem to act as a cathartic; continue the lemonade and milk-punch. June 29th: Breathes with great difficulty; has now very little diarrhœa. After this date the patient grew steadily worse; his face became more puffy; he lay on his right side until he became so feeble as to lie only on his back, and died July 12th. *Autopsy* eight hours after death: The right lung was strongly adherent to the thoracic parietes, and pushed into the upper part of the chest by a quantity of dirty yellow serum. There was some similar fluid in the left pleural sac, and the peritoneum contained several ounces of the same. The liver was normal. The spleen was greatly enlarged but quite firm. The small intestine was thin and distended with gas; the solitary follicles were enlarged to the size of pin-heads. The colon also was very thin, and its solitary follicles were enlarged. The rectum was thickened and contracted.—Assistant Surgeon C. Bacon, jr., U. S. A. [No. 328, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the ileum, including the ileo-cæcal valve and a small part of the cæcum. The solitary follicles are slightly enlarged.]

CASE 223.—Private Pleasant Trent, company C, 10th Tennessee cavalry; age 34; admitted from Annapolis, Maryland, June 7, 1864. Diarrhœa and scurvy. [This man appears on the register of the first division of the Annapolis hospital as admitted May 2d—debility—transferred to Annapolis Junction June 7th.] The patient had been for a long time a prisoner at Richmond, Virginia, and was very much reduced. July 17th: It was observed that he was suffering from fever; pulse strong and frequent, skin hot and dry, tongue thickly coated with a white fur, bowels constipated, respiration frequent, headache, and loss of appetite. Ordered a laxative dose of sulphate of magnesia, and continued the lime-juice and porter which he was taking. July 18th: Bowels have moved; has less fever; slept but little last night; is quite restless. Quinine, beef-tea, porter, and lime-juice. July 19th: Is quite restless and uneasy; has some delirium; slept none last night; pulse 60 and full; tongue thickly coated. July 20th: Still delirious; pulse 60 and easily compressed; constantly picking at objects about the bed. Brandy, milk, and beef-tea given freely; mustard plasters to the abdomen and between the shoulders. July 21st: Is unconscious; sleeps none; lies more quietly, with his mouth open; tongue dry; pulse 64; pupils dilated and unaffected by light; extremities cold; involuntary passages of urine. July 22d: Passed the night without sleep; pupils still dilated but not so widely; pulse 70 and smaller; still has involuntary passages of urine, and is much troubled with hiccough. Brandy, beef-tea, milk, and carbonate of ammonia. July 23d: Lies very quietly; is unconscious; slept none last night; pulse 80 and wiry; hiccough continues. Treatment continued. July 24th: Still unconscious; pulse 120; respiration frequent. Died, July 25th. Since July 17th he has had no cough, no tympanites, and no diarrhœa. *Autopsy* twelve hours after death: Body very much emaciated. The membranes and surface of the brain were normal, but on separating the hemispheres the roof of the ventricles gave way, and about four ounces of liquid escaped; the floor and roof of the ventricles were soft and pultaceous. There were firm pleuritic adhesions laterally and posteriorly on the right side, and tubercular deposits were scattered throughout the right lung, most abundantly at its apex; the left lung was very slightly adherent to the walls of the chest; the pulmonary tissue was of a dark color, and its upper portion was completely filled with tubercular matter, which gradually became more scanty toward the base. The heart was slightly enlarged, and the sac of the pericardium contained about half an ounce of liquid; the cavities of the heart contained firm fibrinous clots. The liver, spleen, kidneys, stomach, and bladder were apparently healthy. On the external surface of the small intestine a few dark-colored patches were observed, which proved, on opening the intestine, to correspond to areas of inflammation and thickening of the mucous membrane. The solitary follicles of the ileum were slightly enlarged, and the colon presented great numbers of superficial ulcers, which varied in size from mere points to nearly an inch in diameter.—Acting Assistant Surgeon W. J. McHench.

CASE 224.—Private H. Behlmer, company C, 165th New York volunteers; age 19; admitted from the barracks at the Relay House, Maryland, August 17, 1864. Chronic diarrhœa. [This man appears on the register of the hospital of the Relay House barracks, Washington junction of the Baltimore and Ohio railroad, as admitted August 13th—chronic diarrhœa—sent to hospital August 17th.] The patient stated that he had suffered from diarrhœa for a month. He was very much emaciated, and unable to walk. The evacuations were very frequent, but there was no pain; tongue dry, smooth, and red; pulse 70; no appetite; much thirst. Treatment: ℞. Compound tincture of opium and tincture of catechu, of each two ounces, tincture of rhubarb one ounce. Take a teaspoonful every four hours. August 18th: Evacuations less frequent; slept very well during the night; complains of extreme weakness; pulse 60. Treatment continued, with whiskey and quinine. Milk diet, soft-boiled eggs. August 19th: Appears better; evacuations less frequent; is still very weak; pulse 60. Continue treatment, with the addition of five grains of subcarbonate of bismuth every two hours. August 23d: Is delirious; pulse 70; evacuations very frequent. Died, August 24th. *Autopsy* twenty-one hours after death: Body very much emaciated. The lungs were normal, but bound to the thoracic parietes by adhesions which were easily broken down. The heart contained large clots. The liver was normal; the gall-bladder was full of bile, and contained some twenty or more gall-stones from the size of a small shot to half an inch in diameter. The stomach was not examined. The intestines had a healthy appearance, except about three feet of the lower portion of the ileum, which were inflamed but not ulcerated.—Acting Assistant Surgeons W. J. McHench and Horace S. Streeter.

CASE 225.—Private John Weiss, company E, 5th New York heavy artillery; age 41: admitted from Camp Parole, Maryland, October 12, 1864. Chronic diarrhœa. [This man appears on the register of the post hospital, Camp Hill, Harper's Ferry,

Virginia, as admitted July 24, 1864—debility—sent to Sandy Hook, Maryland, July 25th. He is borne on the register of the field hospital, Sandy Hook, Maryland, as admitted July 25th—catarrh—transferred to Frederick, Maryland, July 27th. The register of the Frederick hospital records him admitted July 27th—chronic diarrhœa—sent to Baltimore, Maryland, August 1st. He appears on the register of McKim's Mansion hospital, Baltimore, as admitted August 2d—no diagnosis—sent to Annapolis, Maryland, August 3d. The register of the hospital of Camp Parole, Annapolis, Maryland, reports him admitted August 3d—chronic diarrhœa—sent to general hospital October 12th.] The patient stated that he had suffered from diarrhœa for over six months. He was very much emaciated; tongue coated with a dry brownish fur in the centre, and red and dry at the tip and edges; appetite poor; constant thirst; skin dry and cool; pulse 60 and weak; bowels moved three or four times daily; countenance pinched. Treatment: ℞. Sulphate of copper twelve grains, opium ten grains, extract of conium two scruples; make thirty pills. Take one every eight hours; also enemata of laudanum and sulphate of copper in starch-water. He was put on a milk diet. Red wine was allowed liberally; also beef-essence and chicken-broth when he could retain them. After a couple of days he was allowed milk-punch. The patient steadily grew feebler; the pulse became weaker and slower, the last eight days of life it was from 40 to 46 per minute; the cornea of both eyes ulcerated about a week before death, and for the last three days he was semi-delirious. Died, November 10th. *Autopsy:* Body extremely emaciated. The lungs were very dark-colored, and there were a few large tubercles in the upper lobe of the left lung. The heart was normal. The stomach was diminished in size. The duodenum, jejunum, and upper two-thirds of the ileum were but slightly inflamed; the lower third of the ileum, the cæcum, colon, and rectum were thickened and softened. The patches of Peyer were slightly inflamed but not ulcerated; the solitary follicles were slightly enlarged but not ulcerated; a few small points of ulceration were observed in the rectum. The kidneys were somewhat enlarged and very pale. The spleen was enlarged and soft. The pancreas and liver were normal.—Acting Assistant Surgeon Horace S. Streeter.

The next eleven cases were forwarded on medical descriptive lists from the HAMMOND HOSPITAL, Point Lookout, Maryland, Surgeon Anthony Heger, U. S. A., in charge. All the patients were prisoners of war:

CASE 226.—Private William Hipps, company G, 61st Georgia; age 44; admitted August 14, 1863. Diarrhœa. Was taken sick three days before; pulse quite natural. To have a dose of castor oil. After the operation of the oil, the stools continuing to be frequent, twenty drops of laudanum were given three times a day for a few days. The diarrhœa, however, persisted, and various remedies were vainly tried, as subnitrate of bismuth ten grains three times a day, tannic acid and opium, tincture of the chloride of iron, quinine, stimulants, &c. Died, October 24th. *Autopsy* thirty-six hours after death: Body excessively emaciated. Nearly the whole of the left lung was in a state of gray hepatization, and coated with lymph externally; the right lung was congested. The sac of the pericardium contained nearly a pint of serum, and the surface of the heart was coated with fibrinous lymph; the valves were normal; the right cavities contained fibrinous clots; the heart weighed six ounces. The liver was softened, mottled, and fatty, with three peculiar white, hard, spherical bodies on its under surface; it weighed three pounds four ounces. The right kidney was normal but small, weighing three ounces and a half; the left was larger, weighing four ounces and a half. The spleen weighed only three ounces. The stomach was normal, but its coats were very thin. The ileum was congested, and in its lower part a few of the glands of Peyer were ulcerated. The mucous membrane of the rectum and colon was of a peculiar ash-gray color, and had large ulcers throughout its entire extent.—Acting Assistant Surgeon W. W. Bidlack.

CASE 227.—Private B. A. Shaw, company L, 31st South Carolina; admitted October 26, 1863. Chronic diarrhœa. This patient stated that he was taken sick at Morris Island, South Carolina, May 20th. At the date of admission he was very weak and had an exhausting diarrhœa. To take twenty drops of laudanum after each passage. Stimulants; milk diet. Died, November 2d. *Autopsy* twenty-four hours after death: Body much emaciated. The upper lobe of the right lung was adherent by fibrous bands to the thoracic parietes; immediately under the adhesion there was a cavity as large as a hen's egg, filled with dark pus; this cavity had a membranous lining; the lung was hepatized for some extent around it; there were no tubercles; the left lung was normal. The cavity of the pericardium was nearly filled with serum. The heart was well coated with fat; there was a fibrinous clot in the left ventricle; otherwise it was normal. The liver was normal in size, but paler than natural. The spleen was adherent to the diaphragm and enlarged. The kidneys were congested. The mucous membrane of the colon was inflamed, and in patches coated with pseudomembrane; it presented numerous small punched-out follicular ulcers.—Acting Assistant Surgeon W. W. Bidlack. [No. 78, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the transverse colon, with numerous small punched-out follicular ulcers and small pseudomembranous patches scattered over the mucous membrane.]

CASE 228.—Private D. F. Taylor, company A, 20th Arkansas; admitted November 7, 1863. Chronic diarrhœa. The patient stated that he was taken sick in July last; he was very weak. Ordered stimulants and opium pills. November 18th: The diarrhœa has diminished; during the day the patient had a chill. The stimulants were continued, and mustard plasters applied to the extremities. November 19th: Had another chill. Treatment continued. November 20th: He had another chill, during which he died. These chills partook rather of the nature of spasms; during the intervals the patient was able to sit up. *Autopsy* the same day: Body somewhat emaciated. The lungs were normal. The pericardium was distended with serum; there was a large fibrinous clot in the left ventricle, but the heart was otherwise normal; weighed eleven ounces. The liver was softened and enlarged; it weighed four pounds ten ounces. The spleen weighed thirteen ounces. The kidneys were normal. The small intestine was inflamed throughout. The colon was inflamed and ulcerated in patches.—Acting Assistant Surgeon W. W. Bidlack.

CASE 229.—Private T. L. Langford, company D, 55th North Carolina; admitted November 23, 1863. Chronic diarrhœa and scurvy. The patient was extremely emaciated; his gums bleeding; he had daily eight to ten stools, which were somewhat

bloody and mixed with pus; he had also some cough, but no pain in the chest and no night-sweats; the sputa, however, were purulent, and percussion was duller than normal over the whole chest. Treatment: Opium pills, two ounces of whiskey daily. Diet: Bread and milk, chicken-soup, eggs. Died, December 17th. *Autopsy:* The pleuræ were normal, but there was lobular inflammation of both lungs, the patches being of limited extent and of gray-red color; they were not softened, though not so solid as in red hepatization. The heart and liver were normal. There were a great number of ulcers and a great deal of ecchymosis in the transverse colon.—Acting Assistant Surgeon Francis P. Geisdorff.

CASE 230.—Private Robert Moore, company F, 61st Tennessee; admitted November 23, 1863. Chronic diarrhœa. This man had been sick for seven months with diarrhœa and cough. When admitted he complained of pain in the left side of the chest, which was dull on percussion above the third rib. A crepitant rale was heard over the same region, and moist rales over the rest of both lungs. The expectoration was purulent; skin hot; pulse 110. He was much emaciated, and had eight to ten passages daily. Treatment: A grain of opium twice daily; tincture of catechu; whiskey. Diet: Milk and chicken. Died, December 22d. *Autopsy:* The upper lobe of the left lung was hepatized red throughout; in the lower lobe of this lung, and throughout the right lung, the bronchial passages were inflamed. The heart was large. The liver was pale and presented the nutmeg appearance. The mucous membrane of the jejunum was thickened and the larger vessels were much congested. The mucous membrane of the transverse colon and cæcum was very much thickened, red, and inflamed, but no ulcers were found. The cortical substance of the kidneys was very pale.—Acting Assistant Surgeon Francis P. Geisdorff.

CASE 231.—Sergeant T. B. Pett, company B, 44th North Carolina; age 38; admitted November 23, 1863. Chronic diarrhœa. The patient was very much emaciated, and had from six to eight passages daily; these contained some pus but no blood; his abdomen was much contracted, but he was able to walk, and his appetite was good; he continued in this condition until the middle of December. The treatment consisted in the use of opium and camphor pills and stimulants; bread and milk, chicken, eggs, &c., for diet. December 26th: The diarrhœa has increased since the last cold spell of weather; there is also some cough and pain in the chest. To take a tablespoonful of whiskey every two hours. Died, December 28th. *Autopsy:* The posterior portions of both lungs were in the first stage of inflammation, with small limited regions of the same character scattered throughout other portions of both lungs. The intestines were diseased in their whole course. There were some cicatrices in the small intestine, but no ulcers. The colon was ulcerated. The stomach was considerably contracted, its lumen being smaller than that of the transverse colon. Acting Assistant Surgeon Francis P. Geisdorff.

CASE 232.—Private A. T. Brogdon, company E, 47th North Carolina; age 37; admitted November 23, 1863. Chronic diarrhœa and scurvy. This patient had diarrhœa and scurvy for the last six months. At first the muscles of the calves of his legs were affected; for the last four weeks the gums had been bleeding; the teeth were perfectly black; he had lost flesh considerably, but his appetite most of the time was good. He had from four to seven loose stools in the twenty-four hours; they were thin, yellow, and contained at times a little blood. Treatment: One to two grains of opium daily; turpentine emulsion; whiskey. Diet: Bread and milk, chicken, &c. During the month of December the diarrhœa temporarily improved, but the patient gradually continued to lose flesh, and after the first of January, 1864, he became more prostrated; a slight cough set in, with some pain in the chest, sore throat, and difficulty in swallowing. Died, January 7th. *Autopsy* thirty hours after death: The right lung was normal; the left lung contained many softened tubercles, and appeared to be in the first stage of pneumonia. The stomach and intestines were much contracted. The mucous membrane of the cæcum and transverse colon was thickened and of a gray color. A few slight abrasions were found, but no ulcers.—Acting Assistant Surgeon Francis P. Geisdorff.

CASE 233.—Private Jacob Ury, company H, 57th North Carolina; admitted from camp December 23, 1863. Chronic diarrhœa. [This man is borne on the register of the Prison Camp, Point Lookout, as admitted December 11th—dysentery—sent to general hospital December 22d.] The patient stated that he had been sick two months. He had eight or nine stools daily, with but little pain. His tongue was red but moist, and he complained much of thirst. To take tincture of the chloride of iron; chicken and thickened milk. December 26th: Had five stools during the last twenty-four hours. December 28th: Transferred to ward 13.—Acting Assistant Surgeon Geo. Johnson. Ward 13. December 28th: Ordered tincture of ginger, opium, and a cough mixture; nourishing diet. January 5, 1864: Seems to be improving slowly. Continued treatment, with a pill of camphor and opium at bed-time. January 6th: Had but three evacuations in the last twenty-four hours. Treatment continued. January 9th: Abdomen very painful and tender; has considerable fever. Applied a mustard poultice to the abdomen. Died, January 10th. *Autopsy:* Evidences of peritonitis were found, and the mucous membrane of the colon was thickened and ulcerated, especially in its lower portion, where the calibre of the gut was considerably diminished. Acting Assistant Surgeon M. A. Booth.

CASE 234.—Private Thomas D. Hare, company A, 1st South Carolina; age 36; admitted November 23, 1863. Chronic diarrhœa and scurvy. This patient stated that he had typhoid fever three months ago, and has had some diarrhœa ever since; he has bleeding gums; is very weak, and somewhat emaciated. To take ten drops of tincture of the chloride of iron three times daily; extra diet. This, however, did not check the diarrhœa, which continued to average from five to ten passages daily. December 30th: Turpentine emulsion was prescribed, with one or two grains of opium in the twenty-four hours; stimulants. Died, January 11, 1864. *Autopsy:* The mucous membrane of the intestine was softened, red, and in the large intestine presented small ulcers, which were most numerous in the cæcum.—Acting Assistant Surgeon Francis P. Geisdorff.

CASE 235.—Private Alexander Stowe, company E, 11th North Carolina; age 28; admitted from the prisoner's camp, October 26, 1863. Chronic diarrhœa. This man had had diarrhœa for some time; his passages were numerous, bloody, and attended with tenesmus, and he presented evidences of a scorbutic condition. Treatment: Pills of tannic acid and opium; Dover's powder at bed-time; whiskey, &c.; special diet. Under this treatment he improved somewhat until December 1st, when he had a relapse; the stools again became very frequent, and he complained of abdominal pain. He again improved under the same treatment until January 5, 1864, when rheumatism appeared in the muscles of his upper and lower extremities; there

was pain on moving the limbs, and much general debility. Treatment: Iodide of potassium, blisters to the calves of the legs, &c. January 25th: The pain in the limbs is much better, but the patient remains weak and the diarrhœa continues. To take sulphate of quinia, turpentine emulsion, and a Dover's powder at bed-time. January 28th: He got out of his bed, and, while walking about the ward, fell, was carried back to bed and found to be dead. *Autopsy* about twenty-four hours after death: Nothing was found in the organs to explain the cause of death. There was general venous congestion of the body; the blood was dark, and not coagulated in the heart. The brain was normal, with the exception of venous congestion of the membranes. The heart was normal. [The condition of the intestinal mucous membrane is not recorded.]—Assistant Surgeon George McC. Miller, U. S. V.

CASE 236.—Private J. W. McCoy, company A, 3d Tennessee; age 20; admitted November 19, 1863. Chronic diarrhœa. This patient stated that he was taken sick at Fort Delaware, October 17th; could give no particulars of his illness except that he had and still has diarrhœa. Treatment: Pills of nitrate of silver and opium, cod-liver oil, stimulants; extra diet. January 10, 1864: The diarrhœa continues; bowels very loose. Substitute camphor and opium pills. January 15th: Has now but four stools daily. January 18th: Complains of pain in the abdomen; is very weak. Stimulants. January 24th: The diarrhœa has recurred; he still complains of pain in the stomach. February 3d: Stools again reduced in number to four or five daily. February 5th: Dysenteric symptoms have supervened, with anorexia. Substitute Hope's camphor mixture. February 9th: The dysenteric symptoms have subsided. Substitute Fowler's solution, with tincture of opium and cinnamon water. February 14th: Stools diminished in frequency to two or three daily. February 19th: Stools frequent once more. February 23th: Better again; has but two or three stools daily; appetite improving. March 2d: Is troubled with a catarrhal cough. To use a cough mixture containing wine of antimony, syrup of squill and laudanum. March 12th: The cough is relieved, but the diarrhœa has increased; has tenesmus and some blood in the stools. Renew prescription of February 9th. March 16th: Stools are still frequent but not painful, and no blood. Treatment continued. March 17th: Substitute pills of acetate of lead and opium. March 25th: The patient again has a severe cough; on examination of the chest, a good deal of mucous rattling can be heard on both sides; the expectoration is yellowish-white. To take chalk mixture and catechu; a Dover's powder at night. April 5th: The diarrhœa is somewhat better, but the cough is troublesome; there are evidences of pleuritic effusion on the right side. To take five grains of iodide of potassium, in solution, every four hours. April 12th: Diarrhœa worse again. Pills of nitrate of silver and opium, quarter of a grain each, to be taken four times a day. Died, May 5th. *Autopsy:* A great quantity of turbid serum was found in both pleural sacs and in the pericardium; there were old pleuritic adhesions on both sides, especially the right; crude tubercles were scattered through both lungs; some of them had calcified. The right side of the heart contained a yellowish fibrinous clot. The liver was small; the spleen very soft. A number of very large ulcers, some of them as large as a twenty-five cent piece, with callous thick borders, were observed in the small intestine. The colon was slate-colored, and presented a number of ulcers, which, however, were much smaller than those in the small intestine. The mesenteric glands were greatly enlarged. In the left kidney there was a cavity which contained a dirty yellowish chalky deposit.—Acting Assistant Surgeon W. W. Bidlack.

The next four cases are from the case-book of the FREDERICK HOSPITAL, Maryland, Assistant Surgeon Robert F. Weir, U. S. A., in charge.

CASE 237.—Captain J. M. Mott, company K, 5th Wisconsin volunteers; age 45; admitted July 18, 1863. Colic. The patient stated that he had suffered from diarrhœa for some time past, but that it had not been troublesome. The remedies prescribed relieved the pain, and on the evening of the third day he considered himself able to sit up, but was forbidden by his attending surgeon. The patient's pulse was not at any time accelerated, nor was there any heat of skin, tympanites, or tenderness on pressure over any portion of the abdomen. July 23d: The patient was allowed to sit up at noon, and sat up all the afternoon, expressing himself as feeling perfectly well. He ate a hearty supper at 5 P. M., and about an hour after was attacked with a violent pain in the bowels, and died at 8 P. M. *Autopsy* fourteen hours after death: Thoracic viscera healthy; there were evidences of recent peritonitis throughout the entire abdominal cavity, which contained about three pints of turbid serum of a decidedly fæcal odor. On examining the ileum, ulceration of the solitary glands was found throughout its entire extent; two of these ulcers had perforated; there was also ulceration of the large intestine.—Surgeon Charles E. Swasey, U. S V.

CASE 238.—Private James Harvey, company K, 26th Massachusetts volunteers; admitted September 14, 1864. Acute dysentery. The patient when admitted had bloody dejections every five minutes, and complained of severe pain in the region of the bladder; he was unable to pass his urine; it was drawn off by the catheter, and lead and opium pills were ordered. September 15th: Continued pills, and ordered injections of acetate of lead and laudanum; applied a mustard poultice to the hypogastric region; beef-tea and farinaceous diet. He died during the night of the 15th. *Autopsy* ten hours after death: There was slight peritoneal inflammation; the mucous membrane of the colon was much inflamed, and in the ascending and transverse colon there was some ulceration; the coats of the colon were thickened; the mucous membrane of the rectum was highly injected.—Acting Assistant Surgeon Richard W. Mansfield.

CASE 239.—Private Alexander Smith, company I, 1st Vermont heavy artillery; age 39; admitted October 12, 1864. Dysentery. This patient was admitted as a convalescent from chronic diarrhœa. His bowels were still moved about twice a day, but the passages were nearly healthy; there was very little pain in the bowels. No medicines were prescribed; light diet. October 14th: Is still improving, able to be about and out of his tent; volunteered to assist in nursing, and was permitted to do so. October 16th: Symptoms of acute dysentery have made their appearance; there are frequent bloody discharges, accompanied by tenesmus and pain in the bowels; the skin is hot; pulse rapid; tongue dry and brown To take three times daily a pill containing a grain of opium and two of acetate of lead; also an ounce of brandy with the alcohol partially burnt off, four times a day. October 17th. Symptoms the same. To take two grains of opium three times a day; the burnt brandy continued.

October 18th: The stools are still more frequent and the abdominal pains more severe. To take a grain of opium after each stool, and a laudanum injection three times daily. October 19th: The stools are less frequent and not so bloody. Continue treatment. October 20th: The patient continues more comfortable. A grain of opium every four hours; continue the brandy and injections. October 21st: The stools have again increased in frequency; the abdominal pain has recurred; injections not retained. Ordered hot fomentations to the abdomen; brandy increased to eight ounces during the day; a grain of opium in suppository every four hours. Died, October 23d. *Autopsy:* The mucous membrane of the rectum and colon was extensively ulcerated; the mucous membrane of the ileum was injected and softened, but not ulcerated.—Acting Assistant Surgeon T. O. Cornish. [No. 835, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the colon, with extensive and deep diphtheritic ulcers.]

CASE 240.—Private Marion Ardrey, company D, 24th Iowa volunteers; age 18; admitted January 2, 1835. Chronic diarrhœa. [This man appears on the register of the depot field hospital, Winchester, Virginia, as admitted from his regiment January 1st—diarrhœa—sent to general hospital January 2d.] Was first seen by the reporter January 18th; he was then much emaciated, but his appetite was fair, and he appeared to digest his food pretty well. He complains of slight diarrhœa, and has two or three evacuations daily; these are frequently large and thin, but not attended with pain. The abdomen is flat, and there is no tenderness on pressure. Ordered three grains of sulphate of quinia and a wineglassful of infusion of calumbo three times a day; opium and astringents for the diarrhœa. January 22d: Condition about the same, the diarrhœa perhaps somewhat better; the patient is walking around the barrack, but complains of slight difficulty in using his lower extremities. January 24th: The diarrhœa is still improving, but the patient has still less control of his lower limbs, and is scarcely able to stand. He was advised to go to bed. At half-past nine in the evening he complained of intense pain in the abdomen, for which a dose of morphia was administered. He died next morning, January 25th, at 7.30. *Autopsy* four hours after death: Body much emaciated. The brain was not examined. The mucous membrane of the bronchial tubes was inflamed and thickened, but both lungs were crepitant throughout. The pericardium contained an ounce of limpid serum. The heart was quite small. The liver was normal; the gall-bladder much distended with thin light-colored bile. The spleen was congested. The kidneys were large but healthy. In the ileum Peyer's patches were extensively diseased, and many of them were in an advanced state of ulceration; the solitary glands were also ulcerated. The mucous membrane of the transverse and descending colon was much inflamed, and ulcerated at numerous points.—Acting Assistant Surgeon Wm. S. Adams.

The next twenty cases are from the case-book of the CUMBERLAND HOSPITAL, Maryland, Surgeon John B. Lewis, U. S. V., in charge:

CASE 241.—Private William Cook, company K, 156th Ohio national guards; age 32; admitted August 5, 1864. Acute diarrhœa. The patient stated that he had been sick over two weeks; often had ten or fifteen stools a day; was a stout, healthy man when he enlisted. He was very much emaciated, and had to be carried from the ambulance on a litter; the condition of his circulation, however, was good; the abdomen was slightly tympanitic and painful on pressure. Directed emulsion of turpentine containing laudanum every three hours. August 6th: The patient rested tolerably well last night; pulse 96; tongue moist and cleaning; appetite tolerably good. August 7th: Slept well last night; pulse 92; evacuations less frequent; bowels still slightly tympanitic; appetite tolerable. August 8th: There has been no movement of the bowels since yesterday; abdomen very tympanitic; respirations 36. Ordered injections of salt water, followed by injections of castor oil. August 9th: Bowels not yet moved; pulse 130 and almost imperceptible; patient complains of great distress in præcordial region; the abdomen is enormously distended; everything swallowed regurgitates from the stomach. Ordered a drachm of calcined magnesia; the injections to be repeated. Died, August 10th. *Autopsy* three hours after death: Extreme rigor mortis; froth escaping from the nostrils. There were extensive pleuritic adhesions on both sides. The peritoneal cavity contained a small quantity of pus. The stomach and intestines were so greatly distended with flatus that the diaphragm was pushed up to the level of the fourth rib. The intestinal mucous membrane was more or less inflamed from the pyloric orifice to the rectum. The liver and spleen were considerably enlarged.—Assistant Surgeon David Shanor, 6th West Virginia volunteers.

CASE 242.—Private John Wimer, company M, 3d Virginia cavalry; age 21; admitted August 19, 1864. Chronic diarrhœa. The patient stated that he enlisted about six months ago. His health previously had been good, and continued so until his present illness. Previous to his arrival here he had been five days in hospital at New Creek, Virginia, and one day and night in Cumberland. It is noteworthy in this connection that nearly all the cases sent from New Creek have presented malignant typhoid symptoms. August 20th: Tongue coated with a whitish-brown fur; pulse rapid and wiry; skin harsh, dry, and cool; countenance flushed and anxious; abdomen tender on pressure, particularly in the iliac region; frequent dark liquid stools. ℞. Tincture of camphor, tincture of opium, tincture of rhubarb, tincture of capsicum, essence of peppermint and fluid extract of ginger, equal parts. To take forty drops in whiskey every four hours. Also ℞. Tannin one drachm, powdered ipecacuanha five grains, powdered opium eight grains, powdered camphor six grains; make six powders. Take one every four hours between the doses of the former medicine. Apply a mustard plaster to the abdomen. Under this treatment the diarrhœa was checked and the patient seemed to improve considerably for a few days, after which he grew worse again. August 29th: Pulse 100 and irritable; tongue brown and dry; cheeks darkly flushed; skin hot and dry; abdomen tender and tympanitic; bowels constipated; delirium and jactitation. Ordered half an ounce of castor oil, with ten drops of oil of turpentine; after operating, to take quinine three times daily and ten drops of spirits of turpentine every two hours; a dose of morphia at bed-time. Whiskey-punch and milk diet. August 30th: Rested well last night. The cathartic has operated well; the abdomen is soft and less painful, but still sensitive to pressure; pulse 83 and full; countenance darkly flushed; tongue moist and red. Continue treatment. September 3d: Pulse 83; tongue dry and glazed; abdomen very painful on pressure; diarrhœa has again set in; the stools are frequent, thin, fetid, and muco-purulent, and are accompanied by tormina and tenesmus; there is no delirium. Continue treatment, but substitute a Dover's powder for the morphia at bed-time. September 10th: Has been

improving since last report, but the diarrhœa still continues. September 21st: Worse again; symptoms about as recorded on the 3d, with the addition of delirium and subsultus tendinum. After this, with occasional periods of improvement, followed by recurrence of all the symptoms, the case progressed steadily to a fatal termination. The later stages were characterized by sordes on the teeth; a dry, red, glazed tongue, with blackish stripe in the centre; harsh, dry, but cool skin; anxious countenance; great emaciation; petechial discoloration on the abdomen; and small, slimy, frequent stools, which were tinged with blood and mingled with pus. Tonics and stimulants were persisted in to the last. Died comatose, October 9th. *Autopsy* next day: Body greatly emaciated; abdomen sunken. The brain and the thoracic viscera were not examined. The jejunum and upper part of the ileum were comparatively healthy. The lower part of the ileum and the colon presented patches of inflammation, with ulcers and gangrenous spots. The colon was also considerably thickened. The omentum and mesentery were congested. The kidneys were enlarged. The liver enlarged and fatty. The spleen dark and congested.—Acting Assistant Surgeon Austin W. Holden.

Case 243.—Private Patrick Murphy, company A, 2d Maryland volunteers; age 28; admitted October 12, 1864. Chronic diarrhœa. Nothing was learned of his previous history; had evidently been sick for some time. [This man appears on the register of the hospital of the 2d Division, 9th Corps, as admitted September 15th—malarial fever—sent to hospital September 22d. He is borne on the register of the depot hospital, 9th Corps, City Point, Virginia, as admitted September 22d—remittent fever—sent to hospital September 26th. The register of the Beverly hospital, New Jersey, shows that he was admitted to that hospital September 28th—sent to general hospital October 12th.] October 13th: Patient is very much emaciated and very feeble; pulse rapid and feeble; abdomen tender on pressure; stools frequent, dark, thin, and slimy; tongue red, glazed, and dry; anorexia, with nausea. Rested well last night, having taken an opiate. Directed a hot sponge-bath, followed by turpentine stupes to the abdomen. ℞. Tannin one drachm, powdered ipecacuanha five grains, powdered camphor six grains, powdered opium eight grains; make six powders. Take one every four hours; also a tablespoonful of chalk mixture every four hours alternately with the powders. Whiskey-punch; milk diet. October 15th: Pulse 110 and very feeble; sordes on the teeth; skin cool, dry, and harsh; has from eight to ten dark fetid stools in the twenty-four hours, with severe tenesmus, so that he remains on the vessel straining half an hour at a time. Discontinue the chalk mixture; give quinine instead, and ten drops of oil of turpentine three times a day; solution of morphia at bed-time. The patient grew steadily worse, and died October 18th. He was at no time delirious, and retained his consciousness till the last. *Autopsy* five hours after death: Body greatly emaciated; abdomen sunken. The brain and thoracic organs were not examined. There was a quantity of extravasated fluid, smelling strongly of whiskey, in the cavity of the abdomen. The peritoneum was everywhere highly vascular. The stomach was distended. The lower part of the ileum and colon were inflamed, and presented numerous patches of ulceration and several minute perforations; [does not state whether in ileum or colon.] The colon was especially diseased and greatly thickened. A quantity of scybala was impacted in the cæcum. The spleen was enlarged. The liver dark and congested; the gall-bladder distended with normal bile. The kidneys were normal.—Acting Assistant Surgeon Austin W. Holden.

Case 244.—Private Jacob Tolbert, company B, 10th West Virginia volunteers; age 37; admitted November 9, 1864. Chronic diarrhœa. [This man appears on the register of the Sheridan hospital, Winchester, Virginia, as admitted November 1st—diarrhœa—sent to general hospital November 7th.] The patient was extremely weak and emaciated; bowels very loose; had a slight cough; moderate appetite. Ordered turpentine emulsion and laudanum every two hours; also a cough mixture containing syrup of squill and syrup of ipecacuanha. November 13th: Added quinine, tincture of iron and whiskey; milk diet. November 18th: Pulse 64; complains of dysuria; diarrhœa no better. Continue the tonics and whiskey; substitute for the other medicines a teaspoonful of tincture of catechu every three hours, and pills of extract of nux vomica and morphia three times a day. November 20th: Still worse; is drowsy, and complains of pain in the umbilical region. Substitute subnitrate of bismuth for the catechu. A mustard plaster to the abdomen. Beef-essence and milk-punch. Died, November 23d. *Autopsy* three hours after death: Rigor mortis slight; body extremely emaciated. The cæcum was adherent to the surrounding parts and perforated. About two ounces of liquid fæcal matter were found in the pelvic cavity. The mucous membrane of the colon was extensively mortified. The heart was pale and flabby, its walls thin. The other viscera were normal. The effusion of fæcal matter was supposed to be very recent from the fact that there was no peritoneal inflammation.—Assistant Surgeon David Shanor, 6th West Virginia volunteers.

Case 245.—Private Michael Stringer, company C, 5th New York artillery; age 46; admitted July 10, 1864. Diarrhœa. The patient stated that he enlisted February 10, 1862, at which time he was a stout, healthy man, except that he had a chronic ulcer on the right leg. He remained healthy until the autumn of 1863, when he had an attack of erysipelas. He stated also that he had diarrhœa for two days before admission. He admits that he has been intemperate all his life. First came under the care of the reporter October 27th. At this time he was extremely emaciated and barely able to walk about; had from four to six dejections daily—not constantly, but with intervals of constipation. ℞. Extract of nux vomica nine grains, sulphate of morphia two grains; make twelve pills. Take one three times a day, before meals. Two ounces of whiskey three times a day; milk diet exclusively. November 2d: The dejections have diminished in number to two or three daily. The patient is hopeful; his appetite good. He continued to improve gradually, and apparently gained strength till November 26th, when the dejections became more frequent, and some tenderness of the abdomen was noticed. Prescribed a turpentine mixture containing laudanum; continued the nux vomica pills and whiskey. November 30th: The dejections are again reduced to two a day, but the emaciation is steadily increasing, and there is some œdema in the lower extremities. Continue treatment; add a teaspoonful of sweet spirits of nitre every four hours. December 12th: The diarrhœa is checked, but the œdema of the lower extremities has increased, and there is considerable serous effusion in the abdominal cavity; the breathing is hurried and difficult; the skin dry; the secretion of urine is slightly deficient. Paracentesis abdominis was practiced, and a very large quantity of serum was drawn off. To take three grains of blue mass at noon and at bed-time. Continue the sweet spirits of nitre, the turpentine mixture, and the whiskey. December 14th: Seems considerably better; pulse 64; tongue moist; has some appetite; bowels regular. December 20th: Pulse 84; tongue clean and moist; the abdomen is refilling; there is considerable cough; bowels still regular.

Died, December 23d. *Autopsy* seventeen hours after death: Rigor mortis slight; body extremely emaciated. The right lung was everywhere adherent to the pleura costalis, diaphragm, and pericardium; the left lung was adherent at its apex, and contained some tubercular deposit. The heart was very small and flabby; there was a pearly-white, shining, smooth spot, about an inch in diameter, upon the interventricular groove. The liver was small, hard, and in appearance corresponded to the descriptions of the hob-nail liver; the gall-bladder was very much distended with bile. Both kidneys were congested and very small; there was an ecchymosed spot, half an inch in diameter, on the convex surface of the left one. The mesenteric glands were enlarged, many of them tuberculous. The bladder was contracted, and coated externally with a thick layer of coagulable lymph. The intestines were distended with gas; the great omentum contracted and drawn up close to the colon. All the abdominal viscera were spotted over with coagulable lymph. [The condition of the intestinal mucous membrane is not recorded.] Assistant Surgeon David Shanor, 6th West Virginia volunteers.

CASE 246.—Private Isaac J. Ferrell, company H, 4th West Virginia volunteers; age 23; admitted November 5, 1864. Typhoid fever. The patient was feeble; pulse 100; tongue dry; abdomen tympanitic; diarrhœa. November 6th: Ordered a mixture containing quinine and oil of turpentine, and a chalk mixture, to be taken alternately; an ounce of whiskey every three hours. In the course of a few days the diarrhœa was checked, the tongue became moist, and the appetite improved. The patient seemed to do very well until November 20th, when jaundice set in, and the diarrhœa again became troublesome. A combination of blue mass, opium, and acetate of lead was prescribed. November 26th: There being no improvement, pills of nitrate of silver and opium were substituted, and astringent injections administered. This treatment was continued for several days without checking the diarrhœa. A combination of mercury with chalk and opium was then tried, also without effect. December 17th: A combination of extract of nux vomica, sulphate of copper, and opium was prescribed, and December 21st, a turpentine emulsion containing carbonate of ammonia. Died, December 26th. *Autopsy* twelve hours after death: Body extremely emaciated; skin jaundiced. The thoracic viscera were healthy. The gall-bladder was much distended with bile. The pancreas was indurated and livid. The stomach was healthy, with the exception of slight congestion near the cardiac orifice. The jejunum was dark-colored, congested, and contained a quantity of bilious matter. The ileum presented the same appearance. The large intestine was ulcerated throughout its whole extent.—Acting Assistant Surgeon Sample Ford.

CASE 247.—Private Henry Pierson, company D, 5th Michigan cavalry; age 24; admitted October 29, 1864. Chronic diarrhœa. [It appears from the register of the Lincoln hospital, Washington, D. C., that this man was admitted to that hospital June 16, 1864—chronic diarrhœa—and transferred to another hospital June 27th. He is borne on the register of the Satterlee hospital, Philadelphia, as admitted June 28th—chronic diarrhœa—transferred to Detroit, Michigan, August 2d. He appears on the register of the St. Mary's hospital, Detroit, as admitted August 6th, and sent to duty August 19th. The register of the Cavalry Corps hospital, Winchester, Virginia, shows that he was admitted from the field October 20th—chronic diarrhœa—and sent to another hospital October 28th.] The patient stated that he had suffered from chronic diarrhœa for the last eighteen months. October 30th: He is much emaciated; skin cool, dry, and yellow; tongue red, dry, and fissured; has no appetite; great thirst; pulse 70 and feeble; abdomen tympanitic; had fifteen dejections in the last twenty-four hours. Ordered a turpentine mixture containing nux vomica; also quinine and whiskey. November 3d: Seems better; the tongue is moister; the tympanites has disappeared; the dejections are less frequent. Continue the quinine and whiskey. The patient continued to improve till November 20th, when he procured and ate a large quantity of chestnuts. This produced a relapse; the dejections again became very frequent; the abdomen tender and tympanitic; the tongue dry. Renewed the mixture of turpentine and nux vomica prescribed October 30th. November 25th: The patient has again improved, but his appetite remains poor. November 30th: The diarrhœa has recurred. ℞. Nitrate of silver six grains, powdered opium three grains; make twelve pills. Take one every six hours. Continue the quinine and whiskey; milk diet. December 15th: The patient continues to emaciate and grow feeble; his abdomen is more tender and swollen. Substitute for the nitrate of silver pills the following: ℞. Sulphate of copper two grains, powdered opium four grains; make eight pills. Take one every four hours. The patient continued to grow worse, and died December 30th. *Autopsy* ten hours after death: Body extremely emaciated. There were slight pleuritic adhesions on both sides. The posterior portion of the left lung and the lower lobe of the right were filled with numerous small abscesses. The heart was healthy. The great omentum was contracted, and closely adhered to the transverse colon. The pyloric portion of the stomach was contracted, and there were two ulcers near the pylorus, also one of considerable extent in the greater curvature; several others had existed but were healed. The walls of the stomach were thickened, the rugæ very prominent. The mucous membrane of the small intestine was congested and inflamed in patches. The colon was extensively ulcerated from its arch to the rectum. The ulcers were most numerous in the sigmoid flexure; many were healed, some in process of healing, others still spreading. The liver was congested, bleeding freely on section. The spleen was of normal size, but light-colored and hard. The kidneys were much congested. The mesenteric glands were enlarged, hard, and filled with tubercular deposits. Acting Assistant Surgeon S. B. West.

CASE 248.—Private Thomas Tanner, company I, 15th West Virginia volunteers; age 39; admitted from Sheridan hospital, Winchester, Virginia, November 9, 1864. Chronic diarrhœa. The patient stated that he enlisted in August, 1862. Was a robust, healthy man, and always enjoyed good health. Was taken sick about six weeks ago with diarrhœa. He is of intemperate habits. When admitted he was very much emaciated and quite feeble. November 10th: Pulse 76 and weak; tongue moist; abdomen flat; about six liquid stools a day; skin dry and harsh; appetite moderate. ℞. Extract of nux vomica nine grains, sulphate of morphia three grains; make twelve pills. Take one three times a day; Dover's powder at bed-time; milk diet. December 1st: The diarrhœa has gradually diminished and he has now but one dejection daily. Continue treatment; also an ounce of whiskey three times daily. December 21st. Moderate diarrhœa still continues. Substitute the following: ℞. Subnitrate of bismuth one drachm, sulphate of morphia two grains; make eight powders. Take one every four hours; also quinine and tincture of iron. December 22d: At the solicitation of the patient red wine was substituted for the whiskey. The patient continued comparatively free from diarrhœa, but a cough set in, he gradually sank, and died January 29, 1865. *Autopsy*

fourteen hours after death: There was hepatization of about one-third of the lower lobe of the left lung, which was extensively adherent to the posterior and lateral walls of the chest; the right lung was free from adhesions and healthy. The heart was very small; it weighed five ounces and a quarter. The spleen weighed three ounces. The liver was normal; the gall-bladder much distended with bile. The kidneys were large. The lower portion of the ileum for about fourteen inches above the ileo-cæcal valve was thickened, contracted, and presented spots of ulceration. A considerable portion of the ascending, transverse, and descending colon was likewise very much thickened, and contracted to about half an inch in diameter.—Assistant Surgeon David Shanor, 6th West Virginia volunteers.

CASE 249.—Private John Green, company A, 13th West Virginia volunteers; age 41; admitted January 17, 1865. Chronic dysentery. The patient stated that he had enjoyed good health until he was attacked with acute dysentery while on Hunter's raid in the summer of 1864, and he attributed his illness to the hardships and privations endured on that expedition. He entered hospital at Charlestown, West Virginia, on his return, and after a few weeks' treatment rejoined his regiment and continued to do some duty until a short time before admission to this hospital He was admitted in a state of great exhaustion, and died February 10th. Treatment: Astringents, anodynes, stimulants, &c. *Autopsy* four hours after death: Body extremely emaciated. The brain and thoracic viscera were not examined. The omentum contained no fat. The liver was somewhat enlarged; the gall-bladder was full of bile. The spleen was very small. The mesenteric glands were enlarged and hard. The kidneys were also hard, and their cortical portion appeared to be inflamed. Patches of inflammation were found in the ileum, and the corresponding peritoneal coat was injected. The whole tract of the large intestine from the cæcum to the anus was a mass of ulceration, not a trace of healthy mucous membrane being recognizable.—Acting Assistant Surgeon M. M. Townsend.

CASE 250.—Private James Finch, company M, 5th Indiana cavalry; age 23; admitted from Martinsburg, Virginia, March 15, 1865. Chronic diarrhœa. [The register of the post hospital, Martinsburg, Virginia, reports this man admitted March 7th—chronic diarrhœa—sent to Cumberland, Maryland, March 14th.] The patient was in the last stage of exhaustion from chronic diarrhœa and starvation. He stated that he was taken prisoner near Macon, Georgia, July 31, 1864, and was confined at various places until paroled in February, 1865. Had been sick a long time; attributed his illness to exposure and starvation. His bowels were moved every half hour, and he was so prostrated that he could scarcely talk intelligibly. Treatment: Stimulants, astringents, and nutritious diet. Died, March 18th. *Autopsy* seventeen hours after death: Body extremely emaciated. The skin was of a dark-brown color, as if it had been exposed to the action of smoke for a long time. There was no trace of adipose tissue, and all the tissues were pale and bloodless. The lower lobe of both lungs was firmly adherent to the diaphragm. The lungs were pale anteriorly, and congested hypostatically posteriorly. The heart was pale and flabby, and the pericardium contained two ounces of serum. The liver was large and pale, but firm; the gall-bladder was distended with bile. The spleen was large and pale. The mesenteric glands large and hard. The omentum was entirely devoid of fat. The ascending and descending colon were contracted and extensively ulcerated; in some places the mucous membrane had a gangrenous appearance.—Acting Assistant Surgeon M. M. Townsend.

CASE 251.—Private George W. Willis, company E, 5th West Virginia volunteers; admitted from Annapolis, Maryland, March 19, 1865. This man re-enlisted December 18, 1863. Had enjoyed good health until he was taken prisoner at Berryville, September 4, 1864. Was taken to Winchester, thence to Richmond, afterward to Danville, then to Saulsbury, and finally, February 25, 1865, to Libby prison, where he remained until March 13th, when he was paroled. He is extremely emaciated; pulse 92 and weak; tongue moist and coated; gums scorbutic; throat inflamed; extremities œdematous; there are large blisters on the ankle-joints which discharge a considerable quantity of serum; has loose stools every half hour; urine scanty and of a deep-red color. Had been fed on cob-and-corn-meal bread while a prisoner. Died, March 21st. *Autopsy* twenty-two hours after death: Rigor mortis moderate; body extremely emaciated; abdomen concave. The lungs were very pale, otherwise normal. The heart pale and soft. The peritoneal cavity contained a quantity of serum. The liver was small, pale, and presented the hob-nail appearance; the gall-bladder was pale and empty. The kidneys were pale and soft. [The condition of the intestinal canal is not recorded.]—Assistant Surgeon David Shanor, 6th West Virginia volunteers.

CASE 252.—Private Jacob Rumple, company C, 53d Indiana volunteers; age 35; admitted from Martinsburg, Virginia, March 15, 1865. Chronic diarrhœa. [It appears from the register of the Martinsburg hospital, Virginia, that he was admitted March 7th, and sent to Cumberland March 14th.] The patient stated that he was taken prisoner near Atlanta, Georgia, July 22, 1864, and held at Andersonville and other points in the rebel states until he was paroled, February 26, 1865. He was in a deplorable condition, and had loose passages every half hour, sometimes involuntarily; he had also incessant cough and great dyspnœa. Died, March 21st. *Autopsy* twenty-two hours after death: Rigor mortis extreme; body much emaciated. The heart was large. The pericardium contained two ounces of serum. The right lung was everywhere bound to the thoracic parietes by old adhesions; the posterior portion of the right lung and the upper lobe of the left were hepatized. The posterior portion of the liver was greatly engorged with blood; the organ was bound to the diaphragm and to the transverse colon by strong adhesions. No ulceration was found in any part of the intestinal mucous membrane.—Acting Assistant Surgeon M. M. Townsend.

CASE 253.—Private Lewis Erskin, company D, 23d Ohio volunteers; age 48; admitted March 13, 1865. Acute diarrhœa. This man enlisted in February, 1864. He stated that he had been suffering with diarrhœa for seven days, and had from ten to fifteen dejections daily, with tormina and slight tenesmus. Was not much emaciated; pulse quick and tense; abdomen flat and painful on slight pressure in the track of the colon; tongue moist; appetite good. Ordered ten grains of calomel, to be followed in six hours by a dose of castor oil; next day small and repeated doses of sulphate of morphia. He gradually improved until March 17th; but a few days after a relapse occurred, he rapidly grew worse, and died March 30th. *Autopsy* twelve hours after death: Rigor mortis extreme. The lower lobe of the right lung was hepatized. The intestines were distended with gas. The omentum was very much wasted. The liver was congested and softened; its convex surface adherent to the diaphragm; its anterior border adherent to the colon. The spleen was small. The stomach contained about four ounces of bile. The colon

was thickened and ulcerated throughout its whole extent. One of the ulcers had perforated, and through the opening a quantity of fæcal matter had escaped into the abdominal cavity. The right kidney was congested and adherent to the liver.—Assistant Surgeon David Shanor, 6th West Virginia volunteers.

CASE 254.—Private Lyman Henderson, company B, 1st Michigan engineers; age 20; admitted from Annapolis, Maryland, March 19, 1865. Chronic diarrhœa. The patient stated that he was taken prisoner at Waynesboro', Virginia, February 24, 1865, held at Richmond, Virginia, ten days, and paroled March 13th. He is much reduced by his disease. A chalk mixture containing oil of turpentine and nux vomica was ordered, and laudanum enemata. He seemed to improve for a few days, after which the diarrhœa returned with increased severity. Died, April 4th. *Autopsy* eleven hours after death: Rigor mortis well marked; body extremely emaciated. There were old pleuritic adhesions on the right side. The lower lobe of the right lung was hepatized posteriorly and adhered to the middle lobe, which was also hepatized. The pericardium contained twenty ounces of serum. The heart was soft and flabby. The liver was pale and anæmic; the gall-bladder enormously distended with bile. The spleen was pale. The omentum adherent to the descending colon. The mesenteric glands were indurated. The cæcum was partially adherent to the abdominal parietes. The mucous membrane of the ileum was congested and coated with grumous blood. The mucous coat of the descending colon was inflamed and extensively ulcerated.—Acting Assistant Surgeon E. C. Thomas.

CASE 255.—Private Theophilus Legraux, company E, 30th Massachusetts volunteers; admitted from Harper's Ferry, Virginia, April 7, 1865. Chronic diarrhœa. At the time of admission the patient appeared to be suffering chiefly from severe bronchitis, and the state of his bowels did not attract much attention. A cough mixture was prescribed, and a blister applied to the chest. When first seen by the reporter, April 13th, he was quite feeble; pulse 100; respiration somewhat labored. Ordered an ounce of whiskey every two hours. April 15th: He said he felt quite comfortable, and sat up awhile, but complained a good deal of flatulence, and his abdomen was tympanitic. April 18th: He complained of severe headache; otherwise his condition was unchanged. April 19th: He seemed better in the morning, but had several loose passages. At 9.30 A. M. he rose from his bed for the purpose of going to stool, when he suddenly fell with a groan, and died a few minutes after. *Autopsy* four hours after death: The substance of the cerebrum and cerebellum was very anæmic and quite soft. The membranes of the brain were congested; from four to six ounces of serum were found at the base of the brain and in the ventricles. The trachea and large bronchial tubes were inflamed. The entire left lung and the greater portion of the upper lobe of the right were firmly adherent to the thoracic parietes; the lobes of both lungs were interadherent. The stomach and bowels were so distended with flatus that the liver, which was slightly congested, was pushed up to the level of the third rib. The spleen was enlarged, congested, and easily torn. The mucous membrane of the intestines was extensively disorganized, and, in the right iliac region, the knuckles of the intestine were coated with plastic lymph.—Acting Assistant Surgeon Henry J. Weisel.

CASE 256.—Private William P. Halpin, company G, 192d Ohio volunteers; age 20; admitted from Harper's Ferry, Virginia, April 2, 1865. Chronic diarrhœa. The patient was extremely emaciated and very feeble; skin dry and harsh; tongue dry and thickly coated in the middle, its tip and edges red; no appetite; pulse very quick, small, and frequent; frequent liquid, yellow stools. The patient complained of severe colicky pains after eating, and of muscular pains in the back and lower extremities. April 4th: He had severe muscular spasms, which, however, passed off. His diarrhœa resisted treatment, and he died April 25th. *Autopsy* fifteen hours after death: The mucous membrane of the pharynx and larynx was inflamed, thickened, and ulcerated. The lungs and heart were healthy. The liver was very small, pale, and friable; the gall-bladder was filled with tar-like bile. The spleen was very small, soft, and easily broken down. The mucous membrane of the ileum and colon was thickened, congested, and presented irregular patches of a fungoid appearance, [pseudomembrane?] The mesenteric glands were hard and very much enlarged.—Acting Assistant Surgeon S. B. West.

CASE 257.—Private John Schellhorn, company K, 74th Pennsylvania volunteers; age 30; admitted April 1, 1865. Chronic diarrhœa. The patient stated that he was a native of the Tyrol; enlisted in the United States service in the fall of 1862; had previously enjoyed good health. He was attacked with diarrhœa March 3, 1865, but continued to do duty with his regiment until a few days before admission here. He was not much emaciated; tongue furred and dry; pulse quickened; skin dry; had a loose stool almost every hour; complained of severe pain in the region of the transverse colon. Died, April 30th. *Autopsy* twenty-nine hours after death: Rigor mortis moderate. There were extensive old pleuritic adhesions on both sides. The mucous membrane of the colon was inflamed throughout and had sloughed away in patches.—Assistant Surgeon David Shanor, 6th West Virginia volunteers.

CASE 258.—Private Finley McPherson, company F, 6th Michigan cavalry; age 21; admitted from Harper's Ferry, Virginia, April 14, 1865. Chronic diarrhœa. The patient stated that his health had been excellent before enlisting. He was first taken with diarrhœa while in the swamps of the Chickahominy. He was excessively emaciated, eyes sunken, malar bones prominent; skin cool; tongue dirty and pale; he had ten or fifteen dejections a day. Camphor and opium pills were directed. April 18th: One-thirtieth of a grain of strychnia three or four times a day in fluid extract of ginger was prescribed. Under this treatment he gradually improved, and on the 29th reported that his diarrhœa was completely checked. He was ordered to confine himself to a milk diet, and continue the strychnine at longer intervals. May 2d: The diarrhœa recurred, as he supposed from eating some beef-soup. During the afternoon of May 4th he was attacked with violent and diffused pains in the abdomen, pulse frequent, some delirium. Died, May 5th. *Autopsy* twelve hours after death: Body excessively emaciated. The thoracic viscera were normal. The stomach was enormously distended with gas; its mucous membrane inflamed and ulcerated near the pylorus. The mesenteric glands were enlarged and cheesy. The peritoneum was generally inflamed. The liver was pale. The spleen very small and pale. The mucous membrane of the colon was inflamed and ulcerated.—Acting Assistant Surgeon Henry J. Weisel.

CASE 259.—Private Thomas M. Fuller, company C, 1st Michigan cavalry; age 44; admitted from Harper's Ferry, Virginia, April 6, 1865. Diarrhœa. [The register of the Island hospital, Harper's Ferry, Virginia, shows that this man was

admitted to that hospital February 27th—inflammation of the lungs—and sent to Cumberland April 6th.] This was a very delicate man, of scrofulous diathesis. He stated that he had been sick for four weeks. April 13th: The diarrhœa still continues; the dejections are frequent; the tongue dry and red; appetite poor; thirst; pulse feeble, frequent, and compressible. He complains to-day of dyspnœa, and of pain and soreness in the left side of the chest, which is dull on percussion. Died, May 11th. *Autopsy* seven hours after death: Body extremely emaciated. The left pleural cavity was filled with pus. The left lung was collapsed and only a fourth of its normal size; it formed a firm flesh-like mass adherent to the spine. An abscess had formed between the fourth and fifth ribs, commencing about two inches from the sternum and extending to its left border; it appeared to be making an effort to point externally. The pericardium throughout its whole extent was adherent to the heart. The liver was very small, soft, and flabby. The spleen was pale, large, and very soft. The jejunum, ileum, and ascending colon were inflamed and presented patches of ulceration.—Acting Assistant Surgeon S. B. West.

CASE 260.—Private John Kies, company E, 1st Michigan cavalry; age 30; admitted from Winchester, Virginia, October 29, 1864. Chronic diarrhœa, gunshot fracture of right forearm, and intermittent fever. [The register of the Sheridan hospital, Winchester, Virginia, shows that this man was admitted to that hospital from the field October 20th—gunshot wound—and sent to Cumberland October 28th.] This man was wounded in action at Cedar Creek, Virginia, October 19, 1864, by a musket bullet, which entered the ulnar side of the right forearm and passed through the distal extremity of the radius and ulna, fracturing both bones. The hæmorrhage was very free. His health at the time was not good; he had suffered from diarrhœa for two months, and had had quotidian intermittent fever for six weeks. At the time of admission the wound was inflamed, the hand and arm were swollen, but not very painful. The chills continued to recur at irregular intervals, but were finally checked by the use of quinine. November 14th: The arm and hand were very much swollen, painful, and discharged sanious matter freely. His skin was hot and dry; his tongue coated with a brown fur; the pulse quick and feeble; the diarrhœa very troublesome. The arm was amputated by antero-posterior flaps at the junction of its middle and upper thirds, the patient being under the influence of chloroform. He reacted promptly. November 16th: The diarrhœa is very troublesome. Prescribed a mixture containing catechu and nux vomica. The stump did well, and was completely healed by the first of January, 1865. February 18th: His diarrhœa, which had not troubled him for some time, returned, and a hard dry cough without expectoration set in. Died, May 12th. *Au'opsy* twenty hours after death: There were old pleuritic adhesions on the left side. The left lung was thickly studded with tubercles, and there was a large vomica in the apex which extended into the lower lobe; the right lung was infiltrated with sero-purulent matter, and presented some scattered tubercles. The heart was pale and flabby. The liver small and chocolate-colored: its veins empty. The spleen was small, pale, and firm; weight three ounces. The mucous membrane of the colon was inflamed, thickened, and ulcerated in patches.—Acting Assistant Surgeon S. B. West.

The next seven cases were forwarded, with specimens, to the Army Medical Museum from the JUDICIARY SQUARE HOSPITAL, Washington, D. C., Surgeon Charles Page, U. S. A., in charge until December, 1862; afterward Assistant Surgeon Elias J. Marsh, U. S. A.

CASE 261.—Private Andrew A. Edgarton, 2d company Vermont Independent Sharpshooters; admitted November 18, 1862. Chronic diarrhœa. Died, December 25th. *Autopsy:* Besides extensive ulceration of the colon, both kidneys were full of cysts; when fresh the right weighed twenty-four ounces, the left fourteen ounces. No attention had been drawn during life to the condition of these organs.—Surgeon Jos. S. Hildreth, U. S. V. [Nos. 27 to 29, Medical Section, Army Medical Museum, are from this case. No. 27 is the anterior half, No. 28 the posterior half, of the left kidney. They contain innumerable cysts, which vary from the size of a pin-head to that of a chestnut. No. 29 is the right kidney laid open; it is in the same condition as the left, except that some of the cysts are larger, the largest being the size of an English walnut.]

CASE 262.—Private Richard Poole, company C, 3d New Jersey volunteers; admitted from the army of the Potomac February 15, 1863. Chronic diarrhœa. [It appears from the register of the hospital of the 1st Division, 6th Corps, that this man was admitted to that hospital January 20th—chronic diarrhœa—and sent to Washington February 13th.] The patient was in a dying condition when admitted. Died, February 16th. *Autopsy* twelve hours after death: Body emaciated. The brain and spinal marrow were not examined. The heart and lungs were healthy. The spleen was rather small. The pancreas and kidneys were healthy. The mucous membrane of the colon was softened, thickened, purple in color, and presented a number of follicular ulcers. The mucous membrane of the lower portion of the ileum was thickened and presented a number of small ulcers. The rest of the small intestine and the stomach were healthy. [Nos. 220 and 221, Medical Section, Army Medical Museum, are from this case. The specimens are successive portions of the thickened colon, presenting numerous follicular ulcers. In No. 220 the mucous membrane between the ulcers is slightly coated with pseudomembrane.]

CASE 263.—Private Charles Fehle, company B, 1st New Jersey volunteers; admitted February 15, 1863, with chronic diarrhœa. [It appears from the register of the hospital of the 1st Division, 6th Corps, that this man was admitted to that hospital January 20th, and sent to Washington February 13th; the diagnosis recorded is typhoid fever.] He had been taken sick in the army of the Potomac. Died, February 16th. *Autopsy* twelve hours after death: Body much emaciated. The brain and spinal marrow were not examined. The left lung was healthy; the right lung was very thin, and compressed against the anterior and upper part of the thorax by about two quarts of moderately thick not offensive pus. The pleura costalis was covered by a thick pseudomembrane. The heart was healthy. The liver and kidneys were also healthy. The spleen was very small. The stomach and small intestine were healthy. The mucous membrane of the descending colon and sigmoid flexure was thickened, softened, and presented numerous follicular ulcers from an eighth to half an inch in diameter.—Assistant Surgeon E. J. Marsh, U. S. A. [Nos. 218 and 219, Medical Section, Army Medical Museum, are from this case. The specimens are successive portions of the colon, presenting numerous follicular ulcers, some of which, in No. 219, have coalesced into an irregular excavating ulcer of considerable size.]

CASE 264.—Private Alfred Woodrow, company C, 23d New Jersey volunteers; admitted from the army of the Potomac February 16, 1863, in a dying condition. He stated that he had been taken sick early in December with fever, without chills, but accompanied by delirium. Diarrhœa set in during the fever, and continued after it had disappeared. During the last two or three weeks his bowels have been moved eight or ten times a day. He died the day of his admission. [It appears from the register of the hospital of the 1st Division, 6th Corps, that this man was admitted to that hospital January 20th, and sent to Washington February 13th; the diagnosis was typhoid fever.] *Autopsy:* Body much emaciated. The brain and spinal cord were not examined. The lungs were healthy. The heart healthy but rather small. The kidneys were healthy. The spleen healthy, but adherent to the liver. The smaller curvature of the stomach was congested. The mucous membrane of the descending colon and sigmoid flexure was thickened, softened, and presented numerous ulcers an eighth to half an inch in diameter; the mucous membrane of the rest of the colon was thickened, softened, and of a greenish-gray color. The cæcum was very much congested and inflamed. Peyer's glands were thickened, and there were patches of inflammation through the whole length of the small intestine.—Assistant Surgeon E. J. Marsh, U. S. A. [No. 217, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the descending colon, which is considerably thickened, and presents numerous follicular ulcers.]

CASE 265.—Private Daniel Webster, company G, 27th New York volunteers; admitted from the army of the Potomac February 15, 1863. Diarrhœa. [It appears from the register of the hospital of the 1st Division, 6th Corps, that this man was admitted to that hospital January 20th, and sent to Washington February 13th; the diagnosis recorded is chronic dysentery.] He stated that he had suffered more or less from diarrhœa ever since enlistment in May, 1861, suffering always most after marching. About December 1, 1862, he was confined to his bed, and has not been up since. Died, February 17th. *Autopsy* next day: There were pleuritic adhesions on the left side, and the lower lobe of the left lung was hepatized; the right lung was healthy. The liver, stomach, kidneys, suprarenal capsules, and the greater part of the small intestine were healthy. The mucous membrane of the colon was inflamed and thickened throughout its whole extent, with ulcers, especially in the cæcum and sigmoid flexure; pseudomembranous patches covered much of the surface of the mucous membrane between the ulcers.—Assistant Surgeon E. J. Marsh, U. S. A. [No. 222, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the colon, which is somewhat thickened, frosted with pseudomembrane, and presents a few small follicular ulcers.]

CASE 266.—Private J. G. Beals, company F, 37th Massachusetts volunteers; admitted February 15, 1863. Chronic diarrhœa. [The register of the hospital of the 1st Division, 6th Corps, shows that this man was admitted to that hospital January 19th, and sent to Washington February 14th; the diagnosis recorded is typhoid fever.] He stated that he had suffered for some months with a slight diarrhœa, when, December 27, 1862, he was attacked with measles, followed by a severe cough. During this attack the diarrhœa ceased. While convalescing he suffered two relapses from exposure, and when admitted to this hospital was quite weak, had some cough, and a diarrhœa which had recently come on. His appetite was fair, tongue clean and moist, and pulse 114. There was no special change until February 20th, when he said he felt better, but was much weaker, and died February 22d. *Autopsy* twenty-seven hours after death: Body emaciated; rigor mortis slightly marked; abdomen collapsed; muscles pale. The right lung exhibited scattered yellow tubercles in the upper and middle lobes, with muco-pus in the bronchial tubes; the left lung presented one cavity in the upper lobe as large as a hen's egg, with a number of smaller ones from the size of a pea to that of a hazel-nut; these cavities had yellow opaque walls about one line in thickness; there were some yellow tubercles in this lung, and its lower edge was œdematous. The bronchial glands were hard, enlarged, and filled with black pigment. The heart was small, flabby, pale, and remarkably free from external adipose tissue. The spleen was apparently healthy. The liver showed a marked differentiation between the red and yellow portions, the latter being comparatively large and pale. The mesenteric glands small and pale. The stomach contained a thin mucus mixed with bile, but its mucous membrane and that of the duodenum and jejunum was normal. Peyer's glands were normal. The small intestine was smeared over with thick adhesive mucus, stained with greenish-yellow bile, which was darker in the lower part of the jejunum but lighter through the ileum. There were one or two small ulcers near the ileo-cæcal valve. The colon contained thin yellow fæces; throughout its whole length the mucous membrane was greatly thickened and coated with pseudomembrane. The descending colon and rectum presented numerous ulcers of various sizes from a quarter of an inch to two inches in diameter, the membrane being softened, thickened, and undermined for some distance around the margins of the large ulcers.—Assistant Surgeon E. J. Marsh, U. S. A. [Nos. 223 to 225, Medical Section, Army Medical Museum, are from this case. The specimens are three successive portions of the greatly thickened colon, the mucous membrane of which is coated with a pseudomembranous layer. In Nos. 224 and 225 there are many follicular ulcers, which in three or four patches have extended into eroding excavations, the largest of which is an inch and a half long by an inch wide.]

CASE 267.—Private Shipman Griffin, company C, 122d New York volunteers; admitted February 15, 1863, with chronic diarrhœa. Died, April 3d. [It appears from the register of the regimental hospital of the 122d New York volunteers, near Falmouth, Virginia, that this man was treated in that hospital during December, 1862, and the early part of January, 1863. January 17th, typhoid fever is entered opposite his name; January 19th, sent to division hospital at Aquia Creek. The register of the hospital of the 1st Division, 6th Corps, shows that he was admitted to that hospital January 19th, and sent to Washington February 14th; the diagnosis recorded is chronic enteritis.] *Autopsy:* The colon was thickened, and presented well-marked follicular ulcers. [The condition of the other organs is not recorded.]—Assistant Surgeon Elias J. Marsh, U. S. A. [No. 203, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the descending colon, which is thickened, and presents a number of follicular ulcers.]

The next thirty-three cases are from the case-book and medical descriptive lists of the HAREWOOD HOSPITAL, Washington, D. C., Surgeon Thomas Antisell, U. S. V., in charge

from October, 1862, to September, 1863; Surgeon Reed B. Bontecou, U. S. V., for the rest of the time:

CASE 268.—Private Nathan L. Brown, company C, 4th Vermont volunteers; admitted September, 1862. Chronic diarrhœa. Died, October 31st. *Autopsy:* The viscera of the thorax were normal. The stomach was pale, but otherwise healthy. The lower part of the duodenum appeared somewhat congested. The jejunum and ileum were congested in patches, the intensity of the congestion increasing toward the ileo-cæcal valve. The colon and rectum were very much inflamed; in the ascending colon there were five ulcers, a large one at the commencement of the descending colon, and another, which appeared to be granulating, in the rectum. The mucous membrane of the rectum was thickened. The liver was normal. The spleen considerably enlarged and very much engorged with blood.

CASE 269.—Private Thomas Burt, company E, 29th Massachusetts volunteers; admitted October 7, 1862. Chronic diarrhœa. Died, October 31st. *Autopsy:* The stomach presented the normal appearance, except that its mucous membrane was pale. The small intestine was congested in patches, which increased in intensity toward the ileo-cæcal valve. At the lower end of the jejunum there was an intussusception three inches long. The colon was very vascular, its mucous membrane thickened and ulcerated throughout; in the descending colon were numerous perforations connecting with the peritoneal cavity. The walls of the rectum were thickened; its mucous membrane of a dark-green color. The liver showed no marked evidence of disease; the gall-bladder was distended with bile. The spleen was very much enlarged and congested.

CASE 270.—Private Perry Hite, company E, 2d Pennsylvania volunteers; admitted September 4, 1862. Chronic diarrhœa. Died, November 2d. *Autopsy:* The thoracic viscera were anæmic, but presented no marked evidences of disease. The ventricles of the heart contained colorless fibrin-clots. The stomach was distended with flatus, but healthy. The duodenum slightly congested. The jejunum and ileum were healthy to within two feet of the ileo-cæcal valve; from thence highly congested and inflamed. The colon was inflamed, ulcerated, and presented gangrenous patches, with general abrasion of the mucous membrane. The rectum was inflamed and its lower portion much ulcerated. The mesenteric glands were enlarged and engorged with blood; the mesentery was much congested. The liver was normal. The spleen enlarged and very much congested.

CASE 271.—Private Michael McMahon, company I, 105th New York volunteers; admitted November 11, 1862. Chronic diarrhœa. Died, November 15th. *Autopsy:* The lungs were healthy. The pericardium contained two ounces of fluid. The heart was somewhat enlarged; its ventricles filled with dark coagula. The liver was normal. The spleen much enlarged, congested, and softened. The stomach was large and inflated; its mucous membrane covered with a pseudomembrane the color of bile. The small intestine was normal in its upper part, somewhat congested in the lower part; just above the ileo-cæcal valve were two ulcers, five inches long and six lines wide, which had nearly perforated the gut. The large intestine was thickened, ulcerated, and covered with dark-colored false membrane, but the ulcers appeared to be cicatrizing. The rectum was in a similar condition to the colon, but even more diseased.

CASE 272.—Private Owen Kenan, company C, 2d New York artillery; admitted October 7, 1862. Chronic dysentery. [The register of the Convalescent hospital, Fort Ellsworth, Virginia, shows that this man was admitted to that hospital August 24th—intermittent fever—transferred to Harewood hospital.] Died, November 26th. This patient was found dead in his bed about midnight by the attendant; for some days previous he had been able to sit up, and was supposed to be getting better. *Autopsy:* There was slight effusion beneath the arachnoid, but the brain-substance appeared healthy. The small intestine was congested in patches. The colon, which was distended with gas, contained fæcal matter of fair consistence; the whole tract of the colon and rectum presented innumerable ulcers in a state of cicatrization. The mucous membrane of the rectum was thickened. The liver was congested; the gall-bladder full of bile. The spleen was much enlarged and softened. Both kidneys were in a state of fatty degeneration, which was most marked in the right.—Assistant Surgeon Josiah F. Day, jr., 10th Maine volunteers.

CASE 273.—Private Jewell F. Colton, company L, 2d Maine cavalry; admitted January 2, 1863. Chronic diarrhœa of three months' standing. This man had the diarrhœal countenance, and a painful bloody discharge from the bowels almost every hour; his pulse was small and frequent. He was treated at first with dilute sulphuric acid and laudanum, and the discharges diminished in frequency to from seven to nine in the twenty-four hours, but continued painful. Subsequently pills of tannin, ipecacuanha and opium were resorted to, under the influence of which the discharges decreased in frequency to four or five daily, the pain ceased, the pulse became fuller and less frequent, and the appetite improved. The pills were then discontinued, and laudanum alone given; the stools diminished to two daily, and the patient's condition apparently improved very much, so that twenty-four hours before his death he was sitting up and writing. Died, February 6th, at 9.15 A. M. *Autopsy:* The abdominal cavity contained about twenty-four ounces of serum. The ileum presented several patches of congestion. The colon was thickened, softened, and ulcerated in many places; some of the ulcers seemed to be cicatrizing. The liver was congested. The spleen enlarged. The kidneys and bladder normal. The mesenteric glands enlarged.—Acting Assistant Surgeon H. Hirshfield.

CASE 274.—Private M. T. Remick, company K, 29th Massachusetts volunteers; admitted February 8, 1863, from Windmill Point hospital. Chronic diarrhœa. He was much emaciated. The stools were frequent, for the most part bilious, yellow, and slimy, but sometimes bloody. Died, February 17th. *Autopsy:* Body much emaciated. The heart and lungs were pale and flabby, but otherwise normal. The omentum was almost entirely absorbed. The stomach was contracted, its walls much thickened. The spleen was hard and congested. The liver was enlarged, but apparently healthy in texture. The

gall-bladder was distended with bile. There were extensive peritoneal adhesions, especially along the course of the colon. The mesenteric glands were somewhat enlarged. The small intestines were much congested. The colon and rectum were much inflamed, with spots of ulceration and softening of the mucous membrane.

CASE 275.—Private Edward McMahon, company E, 71st New York volunteers; admitted December 31, 1862. Dysentery of four months' standing. Died, February 20, 1863. *Autopsy:* Body very much emaciated. There were tubercles in the apex of the left lung. The pericardium contained half an ounce of serum, and colorless fibrin clots were found in the ventricles of the heart. The peritoneum was much congested; the abdominal cavity contained eight ounces of serum. The liver was somewhat enlarged and congested. The spleen and pancreas were small. The stomach, duodenum, and jejunum appeared nearly normal. The mucous membrane of the ileum and colon was thickened and softened; that of the rectum was dark-red and much ulcerated. The bladder contained several ounces of urine.

CASE 276.—Private John A. Chollar, company K, 21st Connecticut volunteers; admitted February 8, 1863, from Windmill Point hospital. Chronic rheumatism, with diarrhœa. This man had a feeble pulse and considerable œdema of the feet and legs, but was not very much emaciated or prostrated when first admitted. At that time the stools were frequent and bloody; they afterward became bilious. Treatment: At first a scruple each of Dover's powder and mercury with chalk, divided into six powders, once every four hours; afterward wine, milk-punch, and brandy in small quantities. Died, February 23d. *Autopsy:* Peritoneal adhesions were found along the whole length of the colon, especially in the transverse portion. The stomach was distended with a liquid containing bile. The intestines were filled with fæcal matter of normal consistence, and highly colored with bile. The small intestine was healthy. The large intestine was ulcerated, especially in the sigmoid flexure and rectum; the ulcers were deeply stained with biliary coloring matter; the follicles of the colon were much enlarged. The liver was normal; the gall-bladder greatly distended with bile. The spleen normal. Some of the matter from the colon ulcers, examined under the microscope, was found to contain pus-corpuscles, fat-globules, debris of tissue, and crystals of cholesterin.

CASE 277.—Private William C. Corey, company E, 20th Michigan volunteers; age 22; admitted January 2, 1863. Chronic diarrhœa. Died, March 11th. *Autopsy:* Body much emaciated; rigor mortis complete; suggillation posteriorly. Right lung healthy; left lung adherent. The pericardium was everywhere adherent. Heart normal. The stomach, duodenum, and jejunum were congested. The ileum was thickened, softened, and ulcerated in several places; some pseudomembrane adherent to its lower portion. The colon was thickened, softened, and presented patches of pseudomembrane and many follicular ulcers. The liver was somewhat enlarged. The spleen, pancreas, kidneys, and bladder normal.—Surgeon Thomas Antisell, U. S. V. [Nos. 156 to 159, Medical Section, Army Medical Museum, are from this case. No. 156 is from the lower portion of the ileum, which is thickened, irregularly coated with pseudomembrane, and presents some superficial ulceration. Nos. 157 to 159 are successive portions of the thickened colon, which is irregularly plastered with pseudomembrane, and presents a number of follicular ulcers.]

CASE 278.—Private Charles S. Postles, company C, 1st Delaware cavalry; age 29; admitted January 25, 1863. Diarrhœa. At the time of admission this man appeared to be in feeble health. He said he had been shipwrecked on the coast of New Jersey in the winter of 1852, and had almost perished from exposure to wet and cold. His feet were frost-bitten, and he had not enjoyed good health since. January 27th: Had a slight chill last night. He complains of pain in the head; mouth somewhat dry; tongue slightly coated and of a brownish color; pulse 100 and easily compressible; eyes somewhat suffused; respiration natural. To take two grains of mercury with chalk every six hours. February 2d: Complains that he cannot sleep; pulse 100. To take four grains of Dover's powder every four hours. February 5th: Pulse about the same; skin continues dry; tongue moister and not so dark; less heat of surface than before; still complains of loss of sleep. Continue the Dover's powder. February 10th: Pulse 95; tongue and mouth moister; skin natural to the touch; slight moisture about the forehead and neck. Continue treatment. February 15th: Pulse 90; tongue clean; skin relaxed; slight perspiration. Stop the Dover's powders. To take a tablespoonful of whiskey every hour. February 18th: Patient still improving; pulse 90, fuller and softer; again complains of sleeplessness. Continue the whiskey. To take six grains of Dover's powder every six hours. March 1st: Continues to convalesce; is able to sit up and walk unsupported several steps; appears cheerful, and has a moderate appetite. March 7th: Slight diarrhœa. To take ten drops of laudanum, with twenty of tincture of catechu, every four hours; brandy in tablespoonful doses. March 15th: Discharges from the bowels, consisting of serum and mucus only, very frequent since last night. The patient is quite prostrated, and refuses to take nourishment. To take four grains of quinine every four hours in a tablespoonful of brandy, and alternating with this every four hours a powder containing two grains of acetate of lead, half a grain of tannic acid, and three-quarters of a grain of opium. An enema of starch and laudanum was also directed. The diarrhœa, however, continued unchecked, and the patient died March 19th, at 6 A. M. *Autopsy:* The pericardium was somewhat thickened, and contained about four ounces of serum. Heart and lungs normal; no pleuritic adhesions. The stomach hung perpendicularly, the pyloric end reaching two inches below the umbilicus; its mucous membrane was normal but somewhat pale. The mucous membrane of the lower portion of the jejunum was dark-red and soft. The ileum was not as red as the jejunum, but presented many ulcerated patches with raised edges; these corresponded in position to the patches of Peyer. The colon was very much thickened, ulcerated, and coated with patches of pseudomembrane. Rectum in the same state as the colon. Liver and spleen normal. The gall-bladder somewhat larger than usual, and filled with bile. The left kidney was greatly enlarged, perhaps six times its normal size, and presented numerous cysts filled with fluid, varying in size from a line to three-quarters of an inch in diameter; the right kidney was also full of cysts, and about twice its natural size.—Surgeon Thomas Antisell, U. S. V. [Nos. 161 to 164, Medical Section, Army Medical Museum, are from this case. No. 161 is a portion of the ileum with hypertrophied villi, and a thickened Peyer's patch in which there are two ulcers. Nos. 162 and 163 are successive portions of the colon plastered with pseudomembrane, which has irregularly separated, exposing the

submucous coat, from which the portions of pseudomembrane project as little islets, giving the appearance of coarse granulations. No. 164 is the cystic kidney above described; the cysts were filled, when fresh, with fluid of various colors—yellow, bluish, brownish, and greenish.]

CASE 279.—Private Thomas Nales, company A, 71st Pennsylvania volunteers; age 26; admitted March 5, 1863. This man was much emaciated; pulse 60 and feeble; tongue furred, white in the centre, edges red, papillæ raised. He had from ten to fifteen bloody purulent looking stools daily; there was severe pain in the lower abdomen, and tenderness on pressure, with anorexia and much thirst. Treatment: Blue mass, opium, solution of pernitrate of iron, sulphate of quinia, milk-punch, &c. Died, April 5th. *Autopsy:* The body was much emaciated; the abdomen flat and sunken. There were pleuritic adhesions on both sides. The heart was normal. The liver pale; the gall-bladder much distended. The spleen was four and a half inches long by two and three-quarters wide. The kidneys normal; the bladder distended with urine. The mucous membrane of the stomach and small intestine was much congested. The colon was much thickened, and there were ulcerated patches in its lower portion. The rectum was ulcerated throughout.

CASE 280.—Private William H. Hawkhurst, company G, 17th Connecticut volunteers; age 30; admitted April 21, 1863, with diarrhœa of some duration. [According to the register of the hospital of the 11th Corps this man was admitted to that hospital, then at Brooks' Station, Virginia, April 14th, and sent to Washington April 20th; no diagnosis.] Stools frequent; pulse 100, small, and quite compressible; urine normal. Obstinate vomiting was a prominent symptom. Treatment: A blister to the epigastrium, bismuth and opium, &c. The vomiting, however, continued, and the patient died April 26th. *Autopsy:* Body not much emaciated. There were old pleuritic adhesions on the right side; lungs healthy. Heart slightly enlarged; mitral valve thickened, its free edges covered with vegetations; the tricuspid valve and the aortic semilunar valves somewhat thickened; foramen ovale open, the opening a quarter of an inch in diameter. The stomach contained half a pint of green grumous fluid; its mucous coat was much thickened, softened, and inflamed, the rugæ very prominent. The mucous membrane of the lower half of the ileum, and of the colon, except the transverse arch, was in a similar condition. Liver somewhat enlarged, its structure healthy; gall-bladder distended. Spleen normal. Kidneys enlarged, their cortical portion pale, their pyramids congested.—Acting Assistant Surgeon N. C. Stevens.

CASE 281.—Private Max Uppenheimer, company E, 41st New York volunteers; age 22; admitted April 21, 1863, from the 11th Army Corps. Chronic diarrhœa of four months' standing, with anasarca for the last two months. He was emaciated and pallid; pulse 120 and feeble; had twelve serous, highly offensive stools daily, which were sometimes involuntary. Treatment: Solution of pernitrate of iron, opium, and port wine. Died, April 30th. *Autopsy:* Body emaciated; extremities œdematous. The heart was smaller than usual, but apparently normal. A small encysted calcareous deposit was found in one of the lungs. The abdominal cavity contained eight pints of serum, with floating shreds of organized lymph; numerous small cysts resembling hydatids were attached to the mesentery. The stomach was small, pale, and empty; its mucous coat appeared to be slightly thickened. The intestines were distended with gas. Appearances of recent inflammation were observed in the lower part of the ileum, particularly within six inches of the ileo-cæcal valve, but no ulceration of Peyer's glands. There were numerous minute ulcers in the colon, some of them penetrating to the peritoneal coat; these were most numerous in the descending colon. The liver was healthy; the gall-bladder distended with bile. The spleen was congested and softened, but normal in size. The mesenteric glands were enlarged and somewhat indurated. The kidneys normal; the bladder distended with urine.—Acting Assistant Surgeon Thomas H. Elliott.

CASE 282.—Sergeant John Fröhlich, company F, 98th Pennsylvania volunteers; age 30; admitted April 21, 1863. Diarrhœa of nearly four months' duration, contracted near Falmouth, Virginia, in the army of the Potomac. Died, May 7th. *Autopsy:* Body much emaciated. The upper part of the right lung was firmly adherent to the thoracic parietes; the lung itself was normal; the lower portion of the left lung was hepatized, the rest of the lung congested; there were extensive pleuritic adhesions on this side. Heart healthy; the pericardium contained three ounces of serum. The liver was normal in size but much congested. The spleen very small. The mucous membrane of the stomach was slightly injected. Duodenum and jejunum normal. The ileum was normal to within three feet of the ileo-cæcal valve; below this point it was dark-brown or blackish, much injected, thickened, but not ulcerated. The large intestine was much thickened and darkly congested, but there was no abrasion of the mucous surface. Kidneys of normal size, but much congested.—Acting Assistant Surgeon Odrey D. Brooks.

CASE 283.—Private Jefferson McCullough, company H, 20th Indiana volunteers; age 23; admitted from field hospital, Falmouth, Virginia, April 21, 1863. Chronic diarrhœa. He was very feeble and much emaciated. Died, May 13th. *Autopsy:* A portion of the lower lobe of the right lung was hepatized. The bronchi contained pus. The heart was normal. The mucous membrane of the stomach and small intestine was pale and softened. The mucous membrane of the lower part of the ileum and large intestine was extensively ulcerated; the membrane between the ulcers was pale and softened, with occasional red patches. The liver was healthy; the gall-bladder distended with bile. The kidneys normal; the urinary bladder empty.—Assistant Surgeon Odrey D. Brooks, 26th Michigan volunteers.

CASE 284.—Private Henry C. White, company A, 25th Ohio volunteers; admitted April 21, 1863. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 25th Ohio volunteers, then at Brooks' Station, Virginia, as admitted March 1st—acute diarrhœa—sent to division hospital March 29th. The register of the hospital of the 1st Division, 11th Corps, shows that he was admitted to that hospital March 29th—chronic diarrhœa—sent to Washington April 20th.] Died, May 15th. *Autopsy:* The body was much emaciated. The lungs and heart were healthy. The pericardium contained a small amount of fluid. The stomach was much injected, and small patches of pseudomembranous lymph were adherent at several spots. The duodenum and jejunum were slightly injected. The mucous membrane of the ileum was much injected, and thickly

covered with lymph similar to that in the stomach. The large intestine was coated throughout with a similar exudation, the rectum partially so; no ulcers were observed anywhere. The liver and spleen were normal. The kidneys large.—Acting Assistant Surgeon A. H. Haven.

CASE 285.—Private Charles Blydenburgh, company C, 71st New York volunteers; admitted June 15, 1863. Chronic diarrhœa. Died, June 30th. *Autopsy:* Body not much emaciated. The lungs were normal. The pericardium contained two ounces of bloody serum; the heart was of a dark-purple color and flabby; it seemed to be stained with blood. The small intestine was healthy. There were numerous ulcers throughout the large intestine; the rectum was much injected, and presented numerous small ulcers. The liver was healthy; the gall-bladder moderately full of bile. The spleen and kidneys normal.—Acting Assistant Surgeon A. H. Haven.

CASE 286.—Private Lorenzo Young, company B, 6th Ohio volunteers; age 20; admitted August 17, 1863. Chronic diarrhœa. This man had been sick about four weeks and was greatly emaciated. His pulse was feeble and irregular; tongue dry; dejections frequent and bloody. He complained of pain and tenderness along the track of the colon. There was no tympanites. Died, August 26th. *Autopsy:* Body much emaciated. Heart and lungs healthy. The liver weighed seventy-one ounces; the gall-bladder was much distended with bile. The spleen healthy, weight nine ounces. The stomach was somewhat injected. The duodenum, jejunum, and upper part of the ileum healthy; the lower part of the ileum was very much injected; twelve well-marked old ulcers were counted within a foot of the ileo-cæcal valve. The colon was much ulcerated, especially in the sigmoid flexure. The kidneys were healthy.—Acting Assistant Surgeon Lloyd Dorsey. [Nos. 151 and 152, Medical Section, Army Medical Museum, are from this case. The specimens are successive portions of the somewhat thickened colon. In the lower part of No. 151 there is an irregular ulcer, six lines in long diameter, which penetrates to the muscular coat. No. 152 presents a number of larger ulcers of similar character. These ulcers have apparently resulted from the separation of diphtheritic sloughs.]

CASE 287.—Private Joseph Gerard, company F, 140th New York volunteers; admitted August 18, 1863. Acute diarrhœa. Died, September 14th, at 4 A. M. *Autopsy:* Not much emaciation. The lungs were somewhat congested. The heart and pericardium normal. The liver was fatty, and weighed about seventy-two ounces; the gall-bladder was distended. The spleen normal. The mucous membrane of the stomach was thickened, softened, and slightly congested near the cardiac orifice. The duodenum was slightly congested; the jejunum healthy. The ileum and colon were congested in patches; in the ascending and descending colon the mucous membrane was softened. The rectum was slightly congested. The kidneys were normal.

CASE 288.—Private Henry Henning, 1st Virginia battery; admitted October 10, 1863. Chronic diarrhœa. Died, October 13th. *Autopsy* the same day: Body slightly emaciated. The upper lobe of the right lung was somewhat adherent; the left lung pale but healthy. The pericardium contained three ounces of serous fluid; the heart was normal. The liver weighed about fifty-nine ounces; the spleen eleven ounces. The duodenum was normal; the jejunum congested; the ileum somewhat congested throughout. The ascending and transverse colon somewhat congested and thickened; an old ulcer was observed at the junction of the transverse and descending colon. The rectum was contracted and thickened; its mucous membrane softened and greenish, but not ulcerated. The kidneys were much congested; weight, nine ounces each; on the under surface of the left kidney was a cyst about an inch in diameter filled with cheesy matter. The interior of the suprarenal capsules was occupied by a grumous mass resembling decomposed blood.

CASE 289.—Private Thomas Nugent, 33d company, 2d battalion, Invalid Corps; admitted September 15, 1863. Chronic diarrhœa. Died, October 14th. *Autopsy:* Body much emaciated. The right lung contained several large tubercular masses in its upper lobe; lower lobes healthy; the left lung was a mass of tubercles, and presented several large cavities. Heart normal. The liver was fatty, and weighed about seventy-five ounces; the gall-bladder was distended. The spleen weighed fourteen ounces. The anterior portion of the stomach was congested. The duodenum was healthy; the jejunum slightly congested; the upper portion of the ileum much congested, the middle portion slightly so; the lower portion was much congested and presented several small ulcers. The cæcum was ulcerated; the ascending colon congested and thickened in patches; the remainder of the colon thickened and ulcerated; the rectum studded with ulcers. The kidneys were healthy.

CASE 290.—Private Hiram D. Bussell, company C, 6th Vermont volunteers; admitted October 10, 1863. Chronic diarrhœa. Died, October 15th. *Autopsy:* Body very much emaciated. Both lungs were studded with small tubercles, some of which had ulcerated. The heart was normal. The liver was slightly hypertrophied and somewhat fatty; gall-bladder distended. Spleen softened, but normal in weight. Stomach and upper portion of duodenum congested. The jejunum was thickened and presented patches of ulceration; the upper portion of the ileum was in the same condition, the lower portion healthy. The ascending and transverse colon were thickened and studded with ulcers; the descending colon and rectum were much thickened and extensively ulcerated. The kidneys were enlarged; near the middle of the right kidney was an abscess of some size.

CASE 291.—Private George W. Berg, company A, 155th New York volunteers; admitted October 18, 1863. Chronic diarrhœa. Died, October 26th. *Autopsy:* No emaciation. Lungs normal; pleuritic adhesions on the left side. Heart normal. The liver weighed about sixty-four ounces. The spleen was softened. The stomach normal. The duodenum, jejunum, and upper ileum were thickened, but not ulcerated. The mucous membrane of the ileum near the ileo-cæcal valve was softened. Peyer's glands were not inflamed, nor were any indications of inflammation observed in the colon. The kidneys were fatty, and weighed about eight ounces and a half each.

CASE 292.—Private C. M. Andrews, 11th New York battery; admitted October 10, 1863. Chronic diarrhœa. Died, October 28th. *Autopsy:* Body greatly emaciated. Right lung normal; the left lung hepatized. Slight effusion into the pericardium. The heart weighed about six ounces. Liver and spleen normal; gall-bladder not distended. The stomach was

slightly congested; the duodenum and jejunum congested and thickened; the ileum also was congested, but there was no ulceration of Peyer's patches. The colon and rectum were congested; the ascending colon somewhat ulcerated. The kidneys were normal.

CASE 293.—Private Charles Benedict, company C, 17th Connecticut volunteers; admitted April 21, 1863. Debility from fever and chronic diarrhœa. Treatment at first opium and tannin, then Dover's powder, afterward quinine and iron. May 26th: Was furloughed. May 29th: Returned from furlough laboring under a relapse. He had twenty thin, yellowish, bloody stools during the day. Treatment: Decoction of flaxseed with opium internally, enemata of starch and opium, nutritious diet, sinapisms to the abdomen. On the 30th there were six stools, and hiccough set in; pulse 160; countenance hippocratic; vomiting; profuse cold sweat. Treatment: Lime-water, pills of opium and camphor, sinapisms to the abdomen and neck. Died, May 31st, at 5 P. M. *Autopsy:* The body was not much emaciated. There were pleuritic adhesions on both sides; firm on the right side, slight on the left. The lungs were pale, but apparently healthy. The heart was rather small, pale, and coated with fat; there was a large, fibrinous, yellow clot in the right ventricle. The liver was mottled and fatty; the gall-bladder distended with greenish bile. The spleen was congested and softened. The stomach and duodenum were injected in patches. The jejunum was lead-colored, portions of it much injected. The ileum was much congested; its solitary follicles were enlarged to the size of small shot. The ascending colon was much injected, and showed the cicatrices of former ulcers; the transverse colon was pale; the follicles were enlarged slightly, with minute depressions on their summits; the rectum was pale, and dotted with points of ulceration extending as far upward as the sigmoid flexure.—Acting Assistant Surgeon H. Hirshfield.

CASE 294.—Private B. M. Terwilliger, company C, 143d New York volunteers; admitted from his regiment August 19, 1863. Chronic diarrhœa. Died, November 5th. *Autopsy:* Body greatly emaciated. The heart was normal. There were slight pleuritic adhesions on both sides; tubercular cavities in the upper lobe of the right lung, its lower lobe hepatized. The liver, spleen, and kidneys were normal. There were patches of congestion throughout the whole intestinal canal, especially in the lower portion of the ileum. The mucous membrane of the stomach was softened; that of the rectum thickened.

CASE 295.—Private John S. Winter, company K, 111th New York volunteers; admitted February 1, 1864, from the army of the Potomac. Chronic diarrhœa. [It appears from the register of the regimental hospital of the 111th New York volunteers, then with the army of the Potomac in Virginia, that this man was treated in that hospital for chronic diarrhœa from December 4, 1863, to February 1, 1864.] Died, February 4th. *Autopsy:* The body was considerably emaciated. The thoracic viscera were normal. The stomach was healthy. The lower ileum was congested in patches, but Peyer's patches were not affected. The large intestine was intensely congested and showed minute ulcers throughout. The liver weighed eighty-six ounces; the gall-bladder was very much distended with bile. The spleen was normal. The kidneys large, friable, and well covered with fat.—Acting Assistant Surgeon Lloyd Dorsey.

CASE 296.—Private Joseph Jabbit, company H, 9th New York State militia; admitted from the army of the Potomac February 1, 1864. Chronic diarrhœa. Died, February 4th. *Autopsy:* Body much emaciated. Thoracic viscera healthy. The peritoneal cavity contained a quantity of fæcal matter. The stomach was distended. The duodenum and jejunum were healthy. The lower ileum was intensely congested. Peyer's patches were healthy. The colon was ulcerated; a perforation the size of a silver dollar was found in the sigmoid flexure. The liver was friable, breaking down readily under pressure, but natural in size. The spleen was very small, weighing but two ounces. The kidneys normal.—Acting Assistant Surgeon J. W. Fitzpatrick.

CASE 297.—Private Henry Miller, company I, 26th Michigan volunteers; admitted February 1, 1864, from the army of the Potomac. Chronic diarrhœa. [It appears from the register of the regimental hospital of the 26th Michigan volunteers, that this man was treated in that hospital, then near Stevensburg, Virginia, for diarrhœa from January 14th to February 1st.] Died, February 6th. *Autopsy:* Emaciation extreme. The right lung normal; in the left lung there were from ten to fifteen patches of lobular pneumonia from the size of a chestnut to that of a hen's egg. The heart was normal. The pericardium contained half an ounce of serum. Liver normal. The spleen somewhat enlarged. The pancreas indurated. The stomach, duodenum, jejunum, and the upper three-fourths of the ileum were healthy; the lower fourth was injected, and its mucous membrane softened. The ascending colon was healthy; the remainder of the large intestine was highly injected, and presented numerous ulcers, particularly in the sigmoid flexure. The peritoneal cavity contained about four ounces of straw-colored serum. The bladder was empty.—Acting Assistant Surgeon N. C. Stevens.

CASE 298.—Sergeant Henry Elmer, company F, 16th Pennsylvania cavalry; admitted February 1, 1864, from the army of the Potomac. Chronic diarrhœa. Died, February 20th. *Autopsy:* Thoracic viscera normal. The liver weighed ninety ounces. The spleen was normal. The duodenum, jejunum, and upper ileum were healthy; the lower third of the ileum and the entire colon were livid, and presented patches of ulceration; the mucous membrane was softened. The kidneys were enlarged and fatty.—Acting Assistant Surgeon J. W. Fitzpatrick.

CASE 299.—Sergeant James T. Rook, company D, 26th Michigan volunteers; admitted February 1, 1864, from the army of the Potomac. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 26th Michigan volunteers, then near Stevensburg, Virginia, as admitted December 22, 1863—diarrhœa—sent to hospital February 1, 1864.] Died, March 13th. *Autopsy:* The body was greatly emaciated. There were slight pleuritic adhesions on both sides, but the parenchyma of the lungs appeared healthy. On the anterior surface of the heart was a small, oblong, semi-cartilaginous patch, with fimbriated edges; it did not involve the muscular walls. The stomach and duodenum appeared healthy. The upper third of the ileum was injected; the lower two-thirds were intensely congested, and the mucous membrane much softened. The colon presented patches of inflammation, but there were no ulcers. The liver and spleen were normal. The kidneys were slightly enlarged; the cortical substance was cream-colored, the pyramids natural.—Acting Assistant Surgeon N. C. Stevens.

CASE 300.—Private William Armstead, company C, 2d United States colored troops; admitted January 17, 1866. Chronic dysentery, contracted while on duty with his regiment in Florida. At the time of admission the patient was in a dying condition, and had profuse hæmorrhage from the bowels; this was controlled by astringent injections, and supporting measures were employed, together with opiates and astringents He rapidly sank, however, and died January 23d. *Autopsy:* The solitary follicles of the ileum were enlarged, and there was a deposit of black pigment in the pâtches of Peyer and in the summits of the villi. The colon was thickened, ulcerated, and coated with pseudomembrane between the ulcers.—Surgeon Reed B. Bontecou. [Nos. 704 to 706, Medical Section, Army Medical Museum, are from this case. No. 704 is a portion of the ileum, taken near its middle, in which the solitary follicles are enlarged and the villi hypertrophied. When fresh, the extremity of each villus presented a black pigment deposit. No. 705 is the lower extremity of the ileum, with the ileo-cæcal valve and a small portion of the cæcum. The last Peyer's patch is somewhat thickened; the surrounding mucous membrane presents the same lesions as No. 704. No. 706 is a portion of the descending colon, which is considerably thickened and ulcerated. The ulcers are fringed with pseudomembrane, which hangs in shreds from their edges.]

The next thirty cases are from the case-book and medical descriptive lists of the DOUGLAS HOSPITAL, Washington, D. C., Assistant Surgeon William Thomson, U. S. A., in charge from February, 1863, to September, 1864, and after September, 1865; Assistant Surgeon William F. Norris in charge from October, 1864, to September, 1865:

CASE 301.—Private W. G. Iredell, company H, 28th New Jersey volunteers; age 38; admitted February 13, 1863. Chronic diarrhœa. February 15th, when first seen by the reporter, the patient was greatly prostrated, emaciated, and without appetite. He had six stools in the twenty-four hours; they were thin, partly dark, partly yellow; occasionally scybala were passed, but no blood. There was not much pain or tympanites; pulse 90; skin dry and cool; intellect dull. To take three grains of quinine and one-eighth of a grain of morphia three times a day. A pint of scalded milk daily, and half diet. February 23d: Seems much better; spirits good; pulse 95; skin moist; tongue clean or nearly so; bowels moved four times in the last twenty-four hours; appetite better. Continue treatment and diet. February 28th: Pulse 100; skin natural; no tormina or tenesmus; bowels moved about four times in the twenty-four hours; appetite good. Continue treatment and diet; a Dover's powder at bed-time. March 6th: Tongue moist; pulse 110; bowels moved four times in the last twenty-four hours. There is a good deal of tenderness on pressure in the left lumbar region; appetite tolerable, eats bread and milk. March 9th: The tenderness on pressure in the left lumbar region is greater, and extends to the inguinal region. Bowels moved but three times in the last twenty-four hours; pulse 120; some sordes on the teeth; subsultus tendinum. Died, March 10th. *Autopsy* ten hours after death: Body much emaciated. The omentum was small, devoid of fat, and its vessels much congested. The walls of the stomach were very thin. There were one or two ulcerated points in the small intestine, and a number of small ulcers in the large, chiefly in the descending colon. The liver, spleen, and left kidney were healthy; the right kidney was enlarged.—Acting Assistant Surgeon Henry L. W. Burritt.

CASE 302.—Private Jacob Mehn, company I, 108th New York volunteers; age 34; admitted February 13, 1863. Typhoid fever. This man was taken sick at Aquia Creek and brought here in a very low and emaciated condition after being sick three weeks. He was very feeble; pulse 110; tongue clean and red; stools liquid and frequent. He was treated with powders of opium and tannin; diet of scalded milk. February 27th: Somewhat better; pulse 95; tongue clean and moist; some appetite; stools less frequent. To take powders containing three grains of quinine and one-twelfth of a grain of morphia three times daily. March 2d: Pulse 85; skin moist; tongue clean but rather dry; bowels moved three times during the day; some tenderness in the umbilical and left iliac regions. Continue treatment; two eggs daily. March 12th: Appearance improved, looks much brighter and seems stronger; has moderate appetite; three stools in twenty-four hours; is still very feeble and greatly emaciated, but there is now no abdominal tenderness; tongue slightly red on the edges and inclined to dryness. Since the 6th has had suppositories of opium and tannin after each stool; milk-punch and beef-tea every four hours. March 17th: Is worse again; abdomen tympanitic and tender, the tenderness being greatest over the descending colon; there is no tenesmus; tongue and skin dry. Continue treatment. March 18th: Very weak; pulse 140; tongue and skin dry; considerable thirst; abdomen very tender and tympanitic. He complains of much pain in the epigastric region; had two stools in the last twenty-four hours, they were light-yellow and liquid; there is no tenesmus; micturition painful; the urine normal. The stomach retains stimulants and nourishment very well, but digestion and assimilation are wanting, and emaciation steadily progresses. Died, March 19th.—Acting Assistant Surgeon H. L. W. Burritt. *Autopsy:* Emaciation extreme. There were recent pleuritic adhesions of the lower lobe of the right lung, which was hepatized; the rest of the right lung and the left lung were normal. The heart was small but normal. The liver presented the nutmeg appearance; it was one-third larger than natural. The spleen was somewhat indurated. The pancreas was firm. The kidneys were natural in size and texture, but the cortical portion was somewhat pale. Stomach much contracted. The lower part of the small intestine was injected in patches. The cæcum contained a number of small superficial ulcers. The mucous membrane of the colon was somewhat thickened, and presented numerous large ulcers, between which the mucous membrane was coated with pseudomembrane. In this case no symptoms observed during life called attention to the pulmonary lesion.—Acting Assistant Surgeon F. M. Holly. [Nos. 288 and 289, Medical Section, Army Medical Museum, are from this case. The specimens are successive portions of the colon. In No. 288 the mucous membrane is irregularly coated with pseudomembrane; in the lower portion of the piece is a large irregular diphtheritic ulcer which penetrates to the muscular coat. In No. 289 there are several similar ulcers, but the mucous membrane between them presents very little adherent pseudomembrane.]

CASE 303.—Private J. S. Livingston, company K, 7th Wisconsin volunteers; age 32; admitted March 23, 1863. Chronic diarrhœa. Had contracted diarrhœa in September, 1862, but continued on duty until Christmas, when he was sent to the regi-

mental hospital for debility, having lost forty pounds in weight. [The register of the regimental hospital shows that he was admitted December 24th, and transferred to division hospital March 7th.] He was then transferred to field hospital, where he remained until March 22, 1863. [He appears on the register of the hospital of the 1st Division, 1st Army Corps, as admitted March 7th—chronic diarrhœa—sent to Washington, D. C., March 22d.] The diarrhœa had continued unchanged, averaging about three stools daily, except when temporarily aggravated by hard work or exposure. There had been very little pain or abdominal tenderness; the stools were small and light-colored; appetite good. His diet had consisted chiefly of hard bread and fresh or salt beef. When admitted to this hospital his pulse was nearly normal; tongue moist, and in the center covered with a yellowish-white fur; the skin dry; he had about three liquid light-colored stools daily; no abdominal tenderness; moderate appetite; micturition was frequent but not painful. He was very much emaciated. ℞. Nitrate of silver one grain, powdered opium and blue mass each half a grain, ipecacuanha quarter of a grain, every four hours. Water acidulated with nitric acid for drink; whiskey and beef-essence. March 27th: Substituted three grains of subnitrate of bismuth with quarter of a grain of sulphate of morphia every four hours. Diet: Milk, rice, mutton broth, eggs. April 7th: Seems somewhat better, but still has two or three stools daily; appetite moderate; tongue clean; is able to sit up a little. Discontinue medicine, and give an enema of one drop of creasote in an ounce of mucilage three times daily. April 15th: Two grains of quinine and ten drops of aromatic sulphuric acid three times daily. April 18th: Had five stools during the day, attended with tormina and tenesmus. Continue the quinine; give also bismuth and whiskey. April 20th: Still has five or six stools a day; bilious vomiting has set in, accompanied by loss of appetite. Stop the quinine. April 22d: The vomiting has ceased, but the diarrhœa continues about the same. He has become considerably emaciated; tongue red and dry. ℞. Opium one-third of a grain, acetate of lead two grains, every four hours. April 27th: Continues about the same. ℞. Elixir of opium twenty drops, subnitrate of bismuth four grains, every four hours. Died, May 8th. *Autopsy:* Old pleuritic adhesions about the lower lobe of the right lung; the posterior part of the upper lobe of the lung was hepatized; left lung normal. The liver was slightly enlarged and of a mahogany color. The intestines were somewhat congested in patches throughout their entire length, the congested patches being of a dark mahogany color, but no ulceration could be detected. Peyer's patches and the mesenteric glands were healthy.—Acting Assistant Surgeon Francis M. Holly.

CASE 304.—Private J. W. Hoyt, company G, 17th Connecticut volunteers; age 22; admitted June 14, 1863. Scrofula and diarrhœa. [This man appears on the records of the hospital of the 11th Corps, Brooks' Station, Virginia, as admitted April 27th—scrofula; no disposition recorded.] The patient was a young man of feeble constitution, broken down by poor diet and fatigue. Has been subject to attacks of diarrhœa for some time, but it is now better. His chief trouble is the presence of scrofulous looking abscesses in the neck and arm; pulse 90. Ordered citrate of iron and quinia, extra diet, milk-punch, &c. June 17th: Two abscesses were opened to-day, one under the ear, the other under the chin; they discharged freely; appetite better; bowels regular; pulse 95. June 20th: Continues better except that new abscesses are forming freely in the neck. Ordered iodide of potassium and quinine in syrup of sarsaparilla. June 22d: Severe diarrhœa has set in; the stools are watery and yellow; pulse 100; great prostration and depression of spirits. ℞. Opium, tannin, catechu, and alum, of each one drachm; make fifteen pills. Take one every four hours until the bowels are checked. June 25th: The diarrhœa is somewhat better, but the condition of the patient otherwise is not improved; pulse 100; tongue dry and clean; skin moist and cool. Died, June 27th.—Acting Assistant Surgeon H. L. W. Burritt. *Autopsy* sixteen hours after death: The lungs were congested posteriorly, and the bronchi filled with thick yellow muco-pus. The heart was normal; its right ventricle was empty, the left filled with mixed coagula and fluid blood. The liver was large, but otherwise normal. The spleen contained several abscesses. The mesenteric glands were enlarged. The peritoneum and omentum were much injected. The lower portion of the ileum and the whole of the large intestine were extensively ulcerated, many of the ulcers perforating the muscular coat.—Acting Assistant Surgeon Carlos Carvallo.

CASE 305.—Private Hugh Patterson, company E, 140th Pennsylvania volunteers; admitted July 29, 1863. Diarrhœa. This man had yellow discharges from the bowels, which contained small lumps of undigested food, but no blood. His abdomen was slightly tender on pressure; pulse 80 and feeble; skin cool; perspiration profuse; tongue coated with a white fur in the centre, red on the tip and edges. He stated that he had frequently suffered from intermittent fever since he entered the army. He was treated at first with pills of tannic acid and opium, and subsequently with pills of persulphate of iron, extract of gentian and opium. These measures seemed to control the diarrhœa somewhat, but on the 9th August he suddenly became delirious, his pupils dilated, his pulse very frequent; coma set in, and he died August 10th. *Autopsy* five hours after death: The brain was examined with great care, but nothing abnormal was detected, except, perhaps, some slight congestion of the pia mater. The transverse colon was inflamed, but not ulcerated. The lungs, heart, liver, spleen, kidneys, and stomach appeared to be normal.—Acting Assistant Surgeon William H. Letterman.

CASE 306.—Private Anthony Arne, company K, 10th New York cavalry; age 27; admitted September 20, 1863. Acute dysentery. This man reported that he had been broken down by long marches in Virginia just after the battle of Gettysburg, and contracted a mild diarrhœa, which he neglected. Two weeks prior to his admission he got his feet wet, and the symptoms became more urgent, assuming a dysenteric character. When admitted he was much exhausted and considerably emaciated. During the twenty-four hours following his admission he had seven painful bloody passages, and sank into a state of stupor approaching coma. Died, September 22d. *Autopsy* twenty hours after death: The mucous membrane of the stomach was abraded. The whole large intestine coated with a diphtheritic layer. The gall-bladder filled with very dark viscid bile. The remaining viscera were normal.—Acting Assistant Surgeon Carlos Carvallo.

CASE 307.—Private Adam Hart, company K, 6th Michigan cavalry; age 30; admitted from the army of the Potomac October 10, 1863. Chronic diarrhœa and consumption. This man was admitted in an advanced stage of chronic diarrhœa; he had also a constant cough and purulent expectoration. He stated that a year since he had copious hæmoptysis, which had recurred at intervals. His family have a phthisical proclivity. October 11th: Prescribed turpentine emulsion and elixir of opium; milk diet. October 19th: His stomach became irritable; the diarrhœa and cough are no better. Stop medicines:

brandy. October 21st: Prescribed tannin and opium. Died, November 3d. *Autopsy* fourteen hours after death: There were tubercles in the apices of both lungs, but no great amount of disease. The colon and rectum were extensively ulcerated. The other viscera were normal.—Acting Assistant Surgeon Francis M. Holly.

CASE 308.—Private George Joslyn, company A, 111th New York volunteers; admitted from the army of the Potomac November 4, 1863. Chronic diarrhœa. This patient was first seen by the reporter January 7, 1864. He was then exceedingly emaciated; his eyes sunken; pulse frequent and feeble. He had a continual desire to go to stool; his dejections were very thin, resembling colored water. He died January 15th. *Autopsy:* The solitary glands of the small intestine were inflamed, some of them ulcerated. There were several large ulcers in the patches of Peyer. The large intestine was contracted to about an inch in diameter, its coats much thickened; its mucous membrane was blackened by a deposit of pigment, and studded with numerous ulcers and cicatrices. The liver and kidneys were fatty. The other organs were normal. The brain was not examined.—Acting Assistant Surgeon Henry Gibbons, jr.

CASE 309.—Private Obed E. Taylor, company F, 106th Pennsylvania volunteers; age 35; admitted from the army of the Potomac February 1, 1864. Chronic diarrhœa. [It appears from the register of the regimental hospital of the 106th Pennsylvania volunteers that this man was treated in that hospital for diarrhœa in November, 1863, and again in January, 1864.] This man had been sick about four months. He was very weak, greatly emaciated, and in a very filthy condition. The stools were frequent, very thin, and of an ash-gray color; had severe tormina and tenesmus. A grain of opium was administered at once, with an ounce of whiskey, and a blister applied to the abdomen. February 2d: Slept very little last night; had several involuntary evacuations. ℞. Acetate of lead two scruples, opium ten grains, ipecacuanha one scruple; make forty powders. Take one three times daily; also a laudanum enema three times daily. Stimulants and milk diet. He continued about the same until February 7th, when symptoms of pneumonia of the lower lobe of the left lung set in, for which a blister was applied to the chest and fluid extract of seneka given internally. Milk-punch and beef-tea were freely administered. Died, February 10th. *Autopsy* six hours after death: Body emaciated; rigor mortis well marked. The left lung presented lobular pneumonia in the first stage. The liver was fatty. Peyer's patches were enlarged and injected. The large intestine was ulcerated and coated with pseudomembrane from the ileo-cæcal valve to the rectum. The right kidney was abnormally small. Acting Assistant Surgeon Carlos Carvallo.

CASE 310.—Private Augustus C. Falls, company K, 1st New York heavy artillery; age 18; admitted from Fort Marcy August 5, 1864. Acute diarrhœa. The patient stated that he had suffered from diarrhœa for two weeks, with five or six passages from the bowels daily. His general condition was good. Under treatment the stools diminished in the course of a day or so to two in the twenty-four hours; but the tongue becoming dry, he was ordered, August 7th, to take an ounce and a half of whiskey at dinner. August 10th: Pulse 100 and feeble. Ordered two ounces of whiskey three times daily. August 16th: The diarrhœa is checked; pulse 100 and feeble; is losing flesh. ℞. Citrate of iron and quinia two grains, three times a day. August 17th: Has a little inflammation of the fauces. Prescribed a gargle. August 25th: There is now no diarrhœa; pulse 90 and stronger; slight conjunctivitis is present, and an abscess has appeared over the left parotid gland. August 27th: The abscess was opened, and nearly half an ounce of healthy pus discharged. September 1st: Slight diarrhœa has again appeared; the abscess is doing well; the patient still loses flesh. Continue the quinine and iron, and the whiskey. September 7th: Is still losing flesh; has slight cough; pulse 90. September 8th: No diarrhœa; discovered a cold abscess in the axilla, which was opened and discharged an ounce and a half of thick healthy pus. On examination eight other cold abscesses were discovered in various parts of the body and limbs; these abscesses were all opened at once. They were situated as follows: One in the right axilla; one on the inner side of the middle third of the arm; one on the inner side of the upper third of the right forearm; one on the inner side of the lower third of the right forearm; one over the left breast; two near the spinal column, just inside of the lower angle of the scapula; one in the lower third of the left thigh, over the course of the femoral artery; one in the calf of the right leg. September 10th: The abscesses are all doing well except the one in the axilla, which discharges a black unhealthy pus. The patient is becoming much emaciated, but his cough is better, and he has little or no expectoration. September 14th: Pulse 92 and pretty good. Treatment continued. September 20th: Nearly all the abscesses have healed; there is no cough. September 29th: Has a severe attack of erysipelas in the face; pulse 110 and feeble. Ordered three ounces of whiskey every four hours, and tincture of the chloride of iron; face painted with tincture of iodine. September 30th: The erysipelas is spreading over the whole face; the left eye is closed. October 2d: The erysipelas is subsiding; pulse 100 and not so feeble. October 4th: Has been failing for the last twelve hours; pulse 120 and feeble; there is again a little diarrhœa. October 5th: Was slightly delirious last night; pulse very weak. Died, October 5th. Two days before death both feet became swollen, and spots of ecchymosis appeared on them, as well as along the course of the veins of the legs and on the chest. The abscess in the axilla discharged up to the day of his death. *Autopsy* sixteen hours after death: Rigor mortis very slight; body very much emaciated; spots of ecchymosis on the chest and lower extremities. The right lung was adherent to the walls of the thorax by bands of false membrane, which were easily torn; there were about three ounces of serum in the right pleural cavity; on section of the right lung it was found full of softened tubercles, especially in its posterior portions; there were two small cavities in the superior lobe, one at its apex, the other in the lower part of the lobe; there were no pleuritic adhesions on the left side; the left pleural sac contained about five ounces of serum; there was a deposit of tubercles in the posterior portion of the left lung, which, however, was not so abundant as in the right lung. The heart was rather small, but healthy. The spleen was healthy. The liver a little enlarged, but otherwise healthy. The right kidney was pale and large, the left healthy. The solitary follicles of the colon were prominent, and there were a number of small ulcers in the colon and rectum. The mesenteric glands were slightly enlarged.—Acting Assistant Surgeon David L. Haight. [Nos. 405 and 406, Medical Section, Army Medical Museum, are from this case. No. 405 is a section of the upper and middle lobes of the right lung, presenting a considerable number of discrete cheesy tubercles of moderate size. No. 406 is a portion of the descending colon, presenting numerous follicular ulcers, in many of which the swollen solitary follicles remain as prominent points in the centres of the ulcers, which extend circularly around them.]

CASE 311.—Private Arnold Wick, company H, 93d New York volunteers; admitted September 9, 1864. Chronic dysentery. [The register of the depot hospital of the 6th Corps shows that this man was admitted to that hospital August 11th—remittent fever—and sent to general hospital September 8th.] The passages were not very numerous at first, but the patient speedily became emaciated, and the stools ultimately very frequent. After a time he was attacked with cough and slight expectoration, but these symptoms were not very troublesome till within a day or two of his death, which took place October 17th. *Autopsy:* Body excessively emaciated. The posterior portion of both lungs was engorged with blood, and heavy enough to sink in water. The whole small intestine was greatly inflamed. Peyer's patches were somewhat prominent, and one, close to the ileo-cæcal valve, was ulcerated; the adjacent solitary glands were enlarged to the size of canary-seed. The large intestine was much thickened, and extensively ulcerated throughout its whole extent. The mesenteric glands were enlarged. The kidneys congested.—Acting Assistant Surgeon Henry Gibbons, jr.

CASE 312.—Private Isaac Shadwick, company H, 17th Vermont volunteers; admitted from the army of the Potomac September 9, 1864. Chronic dysentery. [The register of the depot hospital of the 9th Corps, City Point, Virginia, shows that this man was admitted to that hospital August 21st, and sent to general hospital September 8th; no diagnosis recorded.] Died, October 28th. *Autopsy* seven hours after death: No rigor mortis; body very much emaciated. The lungs, liver, kidneys, and spleen were normal. The small intestine and the greater part of the colon were healthy. The upper portion of the rectum was reddened, and presented numerous spots of ecchymosis; the lower two-thirds of the rectum were thickened, very dark-colored, and were the seat of numerous deep ulcers, most of which had penetrated through the mucous coat and several through the muscular coat; a large ascaris lumbricoides escaped from the intestines whilst a stream of water was being passed through them, so that it was impossible to ascertain from what portion it came. The bladder was distended with dark-colored urine.—Acting Assistant Surgeon Carlos Carvallo.

CASE 313.—Musician John Orleman, company C, 10th New York volunteers; age 16; admitted from City Point, Virginia, September 9, 1864. Typho-malarial fever. The patient was exceedingly weak when admitted. September 12th: There was some delirium and diarrhœa. Tonics and stimulants were administered, with the effect of decreasing the stools to one or two daily until September 29th, when dysentery set in and resisted treatment. October 19th: Well-marked symptoms of pneumonia on both sides were developed. Died, October 28th. *Autopsy* twelve hours after death: There were pleuritic adhesions on both sides posteriorly. The lower lobes of both lungs were hepatized. The liver and spleen were of normal size, but a little paler than natural. The small intestine was healthy. There was extensive thickening and ulceration of the colon and rectum, with considerable constriction of the latter, especially in its middle.—Acting Assistant Surgeon George P. Hanawalt.

CASE 314.—Private Abner H. Mundie, company G, 31st Maine volunteers; admitted from the army of the Potomac September 9, 1864. Chronic diarrhœa and bronchitis. [The register of the depot hospital of the 9th Corps, City Point, Virginia, shows that this man was admitted to that hospital August 14th—debility—and sent to general hospital September 8th.] From the date of admission the patient was somewhat flighty, continually desiring to explain his disease. He was much emaciated and very weak. Vomiting occurred several times; it was sometimes brought on by a paroxysm of coughing. The abdomen was very flat, somewhat painful on pressure; the stools thin and frequent; the tongue moist; pulse very feeble and thready. Died, September 16th. *Autopsy:* The lungs were much shrunken and engorged hypostatically; the ramifications of the bronchi were filled with a frothy fluid. The heart was firmly contracted and healthy. The liver was small and very green both superficially and deeply; the gall-bladder was full of very green bile. The spleen and kidneys were softened. The stomach contained three or four ounces of a dark-greenish fluid; its mucous membrane was softened. The small intestine was normal. The large intestine was thickened, and presented numerous follicular ulcers and some patches of pseudomembrane.—Assistant Surgeon William Thomson, U. S. A. [Nos. 393 and 394, Medical Section, Army Medical Museum, are from this case. No. 393 is a portion of the ascending, No. 394 of the transverse, colon; both present numerous follicular ulcers, one of several lines in diameter. The mucous membrane is thickened, and presents, in No. 394, a number of small patches of adherent pseudomembrane.]

CASE 315.—Private Philip Becker, 27th New York battery; admitted from the army of the Potomac September 9, 1864. Chronic diarrhœa. [This man appears on the register of the depot hospital of the 9th Corps, City Point, Virginia, as admitted August 31st—chronic diarrhœa; no disposition recorded.] He stated that he had been sick a long time; did not know exactly how long, but thought it was more than two months. He had lost a great deal of flesh, and was hardly more than skin and bones; had twenty to thirty passages in the twenty-four hours, consisting of yellowish, thin, flocculent matter; his pulse was feeble and about 100. Ordered a pill containing half a grain of nitrate of silver, three times daily, and laudanum enemata. After the first three days he began to improve, and the stools were reduced in number to three or four daily. He died very suddenly and unexpectedly, September 17th. *Autopsy* eighteen hours after death: The colon and rectum were extensively ulcerated, the mucous membrane hanging in fringes; the ulcers in some places had so nearly penetrated all the coats that they tore in removing the gut, although the greatest care was used. The small intestine was not much diseased. The lower Peyer's patches presented the appearance of the shaved-chin, and the neighboring solitary glands were slightly prominent. The other organs were all examined, but nothing abnormal was observed.—Acting Assistant Surgeon David L. Haight. [Nos. 364 to 366, Medical Section, Army Medical Museum, are from this case. No. 364 is from the ascending, No. 365 from the transverse, and No. 366 from the descending, colon, just above the rectum. All the specimens present extensive ulcers, which are fewest in No. 364 and most numerous and extensive in No. 366. The ulcers penetrate to the muscular coat, and appear to have extended by burrowing in the submucous connective tissue; as a consequence, the mucous membrane hangs out in more or less extensive fringes, which are especially remarkable in No. 366.]

CASE 316.—Private Daniel McDonald, company F, 39th Massachusetts volunteers; admitted from the army of the Potomac September 9, 1864. Chronic dysentery. He stated that he had suffered from frequent attacks of diarrhœa during the summer, and that for the last three weeks he had been in field hospital with a severe attack of dysentery. During the summer

he also had an attack of intermittent fever. [This man appears on the register of the hospital of the 1st Division, 2d Corps, as admitted August 9th—diarrhœa; no disposition is recorded. He is borne on the register of the depot hospital of the same division, City Point, Virginia, as admitted August 13th—intermittent fever—sent to general hospital September 8th.] He is now emaciated and feeble; conjunctivæ tinged with yellow; tongue furred; pulse 80. The abdomen is flat and tender to the touch, especially over the transverse and descending colon; he has also a slight bronchitis. His dysentery was partially controlled by astringents and a proper diet, and he was apparently doing well until September 29th, when he was seized with nausea, vomiting, and increased tenderness in the abdomen. From this time he sank rapidly, his pulse became feeble, his skin cool, and he died September 30th, at 10 A. M. *Autopsy* four hours after death: Rigor mortis well marked. Both lungs were firmly adherent to the sides of the thorax; their apices presented several dense fibrinous bands resembling cicatrices, and contained a number of cretefied tubercles, some of which were quite hard, others of a more cheesy consistence. The heart was healthy. The external surface of both large and small intestine was covered with a yellow croupous lymph, beneath which the peritoneum was slightly reddened. The recto-vesical cul-de-sac was filled with a thin yellowish-green pus, and there was a patch of lymph of considerable size on the fundus of the bladder. The small intestine was normal, except that a large cul-de-sac projected from the ileum, opposite its mesenteric attachment, about sixteen inches above the ileo-cæcal valve. The large intestine was much thickened, and presented both follicular ulcers and extensive ragged erosions; the ulcers were very irregular in size and shape, and were most extensive and numerous near the rectum. The liver, spleen, and kidneys were healthy.—Assistant Surgeon William F. Norris, U. S. A.—[No. 400, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the colon, which presents a few follicular ulcers and a number of somewhat extensive erosions.]

CASE 317.—Private Lewis W. Kopp, company H, 48th Pennsylvania volunteers; admitted September 9, 1864. Chronic diarrhœa and pleurisy. [This man appears on the register of the field hospital of the 2d Division, 9th Corps, as admitted August 21st—diarrhœa—sent to hospital August 27th. He is borne on the register of the field hospital, 9th Army Corps, City Point, Virginia, as admitted August 27th—typhoid fever—sent to general hospital September 8th.] He stated that he had been unable to do duty for several weeks on account of a bad cough and diarrhœa. He had a hacking cough but no expectoration, and a troublesome diarrhœa; was much emaciated; had severe night-sweats; pulse about 90; and the brilliant eye of a patient with hectic fever. Respiration was rude on both sides, and percussion quite flat on the right side posteriorly. He says phthisis is hereditary in his family. The symptoms continued with but little change until the 27th, when, toward nightfall, he was suddenly seized with a feeling of great oppression and became quite unable to keep the horizontal position. This feeling passed off in a few hours, but returned with great violence on the morning of the 30th; he rapidly sank, and died during the evening of the same day. On testing the urine by heat and nitric acid it became almost solid from excess of albumen. *Autopsy* fourteen hours after death: The right lung was congested but healthy; in the left pleural cavity there was a large effusion of a greenish-yellow sero-purulent fluid, which had completely compressed the lung against the vertebral column; both lung and costal pleura were coated with a thick layer of lymph. The heart was covered with a layer of fibrinous lymph, and there was in the pericardium a considerable effusion of serum in which shreds and flakes of lymph floated free. The liver was healthy, but adherent to the diaphragm; the adhesions were old and tough. The spleen was contracted and firm. The ileum presented a few ulcers. The large intestine was thickened and ulcerated throughout its entire extent. The left kidney was healthy; the right kidney was situated over the second lumbar vertebra, completely atrophied, and converted into a large cyst containing several ounces of a clear amber-colored liquid,—a patulous ureter led from it and emptied into the bladder at its usual place.—[Nos. 361 and 362, Medical Section, Army Medical Museum, are from this case. No. 361 is the bladder, right kidney, and bifurcation of the aorta. The kidney is converted into a cyst the size of an orange, with fibrous walls about four lines thick. The cyst is connected by a patulous ureter with the urinary bladder. Two renal arteries the size of crow-quills proceed from the aorta just above its bifurcation and ramify in the walls of the cyst. No. 362 is a portion of the thickened colon, the mucous surface of which presents numerous superficial ulcers resembling those produced by the irregular separation of a diphtheritic layer.]

CASE 318.—Private John F. Bell, company I, 8th New York heavy artillery; admitted from City Point, Virginia, September 9, 1864. Chronic diarrhœa. The patient was much emaciated, and had at the time of admission as many as twelve or fifteen passages in the twenty-four hours. The disease yielded to treatment about the latter part of September, after which, under the use of stimulants, he gained strength rapidly. October 17th: He had a relapse which proved uncontrollable. He died, October 22d, rather suddenly, having a pulse of natural frequency though feeble, and appearing tolerably strong until a few hours before death. *Autopsy:* The colon was thickened and presented numerous follicular ulcers, with some pseudomembrane adhering to the mucous membrane between them. [The condition of the other organs is not recorded.]—Acting Assistant Surgeon R. B. Hitz. [No. 462, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the descending colon just above the sigmoid flexure, presenting great numbers of minute follicular ulcers, between which the mucous membrane is frosted with pseudomembrane.]

CASE 319.—Private Robert Haller, company B, 7th New York volunteers; admitted from the army of the Potomac, September 9, 1864. Chronic diarrhœa. [This man appears on the register of the hospital of the 1st Division, 2d Army Corps, near Petersburg, Virginia, as admitted August 30th—fever—thence he was transferred to the depot hospital of the same division at City Point, Virginia, to which he was admitted September 6th—remittent fever—sent to general hospital September 8th.] Died suddenly, at a drinking saloon near the hospital, January 20, 1865. *Autopsy* sixteen hours after death: Rigor mortis well-marked; feet and legs slightly œdematous; several ecchymosed spots on the legs; slight ecchymosis and a cut on the bridge of the nose, caused apparently by a fall shortly before death; a similar bruise, but no cut, on the forehead. The brain and its membranes appeared to be healthy; the ventricles were full of colorless serum, and there was a moderate quantity of similar fluid in the subarachnoid space. Both lungs were firmly adherent to the thoracic parietes, but otherwise healthy, except that in the lower lobe of the right lung there was a pneumonic patch about three inches in extent, and a small abscess, with ragged walls, about half an inch in diameter. The larynx and bronchial tubes were healthy. The bronchial glands were enlarged, and black

both externally and on section. The œsophagus was normal. Several firm fibrinous bands connected the walls of the heart with the pericardial sac; there was quite an amount of fat on the external surface of the heart; the left ventricle contained a small clot, the other cavities were empty; the mitral valve was slightly thickened, the other valves were healthy; the muscular tissue of the heart was firm; the aorta was healthy. The liver was dark-red, firm, its acini distinct; the gall-bladder contained about an ounce of thin orange-yellow bile. The spleen was healthy. The stomach was full of half-digested meat and vegetables; it appeared to be healthy. The small intestine was healthy. All the coats of the large intestine were thickened. The mucous membrane was softened, and presented a few well-marked ulcerations. The kidneys were slightly fatty; the bladder contracted and empty.

CASE 320.—Private James F. Ward, company C, 21st Pennsylvania cavalry; admitted September 9, 1864. Chronic diarrhœa. [The register of the hospital of the 1st Division, 5th Corps, near Petersburg, Virginia, shows that this man was admitted to that hospital August 29th—diarrhœa—and sent to depot hospital September 2d. According to the register of the depot hospital of the same division he was admitted to that hospital September 3d—remittent fever—and sent to general hospital September 8th.] This man, besides the usual symptoms of chronic diarrhœa, manifested slight aberration of mind for some time. He had an almost continual disgust for food, and became ultimately extremely emaciated. Died, January 22, 1865. *Autopsy* fifteen hours after death: No rigor mortis; excessive emaciation. The brain appeared to be quite normal, as did also the lungs and the heart. The liver was normal. The spleen was somewhat smaller than natural, but its texture normal. The kidneys were small and slightly fatty; the bladder was contracted, and contained a small quantity of urine. The small intestine was nearly healthy throughout, the only thing abnormal being some slight patches of congestion in its lower portion. The large intestine was thickened, and presented on its mucous surface numerous small, dark-colored oval ulcerations, many of which penetrated to the muscular coat. These ulcers were found in all parts of the large intestine from the cæcum to the rectum.—Acting Assistant Surgeon George P. Hanawalt.

CASE 321.—Private John Morbly, company F, 180th Ohio volunteers; age 22; admitted February 5, 1865. Diarrhœa and pneumonia. This man had watery, offensive stools; feeble, rapid pulse; dusky, anxious countenance; labored respiration; dry, dark, thickly coated tongue; low delirium, and considerable stupor. There was marked dulness on percussion over the left side of the chest, but with little crepitation; on the right side small crepitation was heard. The expectoration was scanty and difficult at first, but was fairly established under the use of a combination of fluid extract of ipecacuanha, bicarbonate of soda, and sulphate of morphia. Stimulants and beef-tea were administered from the first. Died, February 7th. *Autopsy* sixteen hours after death: The superior lobe of the right lung was found to be completely consolidated, while the middle and lower lobes were collapsed and but slightly engorged. The superior lobe of the left lung was apparently healthy, and the upper third of the lower lobe was hepatized; the remaining portion was but slightly congested, and readily floated in water. The other organs of the chest were apparently healthy, and nothing abnormal was observed in any portion of the intestinal canal.—Acting Assistant Surgeon George P. Hanawalt.

CASE 322.—Sergeant-major George Nichols, 5th United States cavalry; admitted from Winchester, Virginia, January 18, 1865. Chronic diarrhœa. This patient had suffered from diarrhœa for a year. At times the symptoms were very severe, at other times he had but three or four stools in the twenty-four hours. At present the stools are bloody, and accompanied by tormina and tenesmus. He is greatly debilitated, and had upward of thirty-six scanty stools in the last twenty-four hours. An aperient of castor oil was prescribed, to be followed by quarter of a grain of nitrate of silver and one grain of sulphate of quinia every four hours; also an injection of twenty drops of laudanum in thin starch-water three times a day. Stimulants were also prescribed. January 21st: The stools have diminished to eight or nine daily. The patient complains of a cough, which he says he has had for some time; the sputa are thin and yellow. An expectorant mixture was prescribed. January 22d: He complained of external piles; applied an ointment containing tannic acid. January 24th: Complained of weakness in the back; applied a pitch plaster. January 26th: Ordered tincture of the chloride of iron three times daily. February 5th: Has eight or nine passages in the twenty-four hours; is still much debilitated. ℞. Persulphate of iron fifty grains, peppermint water one ounce. Take thirty drops four times a day. February 10th: There is slight fever and headache, for which a diaphoretic was prescribed. February 12th: Symptoms of acute pleurisy set in. Died, February 14th. *Autopsy* twelve hours after death: Body emaciated; rigor mortis well developed. The left lung was collapsed, but connected to the thoracic parietes, and especially to the diaphragm, by pleuritic adhesions; the left pleural sac contained upward of thirty-two ounces of thin yellow serum in which clots of coagulated lymph floated; the superior lobe of the left lung was healthy, its inferior lobe somewhat hepatized; there were slight recent pleuritic adhesions on the right side. The apex of the upper lobe of the right lung contained tubercular deposits; the rest of the lung was healthy. The colon was ulcerated. The other organs were not examined.—Acting Assistant Surgeon Carlos Carvallo.

CASE 323.—Private Samuel B. Turner, company B, 124th Indiana volunteers; age 20; admitted February 5, 1865. Chronic diarrhœa and consumption. This man had suffered from diarrhœa for ten months; he had, when admitted, from four to six stools daily; was much emaciated; had cough and night-sweats. The number of stools was soon reduced to two in the twenty-four hours; but little change was noted in his general condition till about April 1st, when he had an attack of coryza, soon after which the other symptoms became more serious and he was obliged to go to bed. About the 15th of April epistaxis occurred of such a character as to necessitate tamponing the nostrils. Died, April 22d. *Autopsy:* Body excessively emaciated. Both lungs were filled with softened tubercles; the upper lobe of the right lung was honeycombed with small vomicæ; in the apex of the left lung was a large vomica; there were strong pleuritic adhesions on both sides. The bronchial glands were greatly enlarged. The heart was normal; but the pericardium contained eight ounces of clear serum, and several small spots of ecchymosis were noticed beneath the serous membrane. The spleen and kidneys were normal. The liver was large, and near its anterior border there were two small masses of tuberculous matter. There was extensive ulceration of the intestines from the

duodenum to the rectum. Peyer's patches and the solitary glands, especially, were ulcerated; some of them, not yet ulcerated, appeared to be the seat of tubercular deposits. The mesenteric glands were excessively enlarged, and of a light-yellow color.—Acting Assistant Surgeon Henry Gibbons, jr.

CASE 324.—Private James Partington, company E, 1st Delaware volunteers; age 39; admitted July 14, 1865. Chronic diarrhœa. This patient came from Soldiers' Rest, with the information that he was supposed to be insane. He was in fact partly delirious, a condition which continued until death. He complained of no pain, prayed permission to go to a boarding house, and constantly asked for port wine. He was greatly emaciated; was very thirsty; his tongue parched; pulse feeble and frequent. He exhaled a very fetid odor. Died, July 20th. *Autopsy:* Near the sagittal suture the skull was very thin and translucent over four depressions corresponding to enlarged Pacchionian glands. The brain appeared to contain more blood than normal. The small intestine was pale. The solitary follicles of the large intestine were enlarged, with a darkened areola and a black dot in the centre of each. The spleen was small and soft. The other organs were apparently healthy.—Acting Assistant Surgeon Carlos Carvallo.

CASE 325.—Private Wyatt Perkins, company I, 37th Wisconsin volunteers; admitted July 25, 1865, at about nine o'clock P. M. Chronic dysentery. [According to the register of the hospital of the 1st Division, 9th Army Corps, this man was admitted to that hospital July 18th—acute dysentery—and sent to general hospital July 25th.] The patient was moribund; pulse very weak and fluttering; delirium; hiccough. Died, July 26th, early in the morning, about six hours after admission. *Autopsy* eight hours after death: The stomach was distended and inflamed, especially near the pylorus. The pyloric orifice was contracted. The small intestine was nearly healthy. The large intestine was excessively thickened, and presented on the surface of its mucous membrane a number of irregularly oval sloughs from half an inch to an inch in their long diameter, which were arranged transversely to the gut; these sloughs seemed to occupy nearly the entire thickness of the intestine; the peritoneum alone remained intact. The transverse colon was firmly adherent to the liver. The gall-bladder contained two gall-stones the size of ordinary marbles.—Acting Assistant Surgeon Henry Gibbons, jr.

CASE 326.—Private William Koppen, company C, 7th New York volunteers; age 20; admitted June 5, 1865. Chronic diarrhœa. This man was excessively emaciated, and had severe onychia on several of his fingers and toes. He had typhoid symptoms, such as stupor, loose bowels, and sordes on the teeth; very little fever. Treatment: Tonics and nourishing food. June 27th: Cod-liver oil in porter. July 1st: Severe diarrhœa set in. The former remedies were then discontinued, and two grains of quinine directed thrice daily, with tincture of the chloride of iron every four hours; also milk and lime-water ad libitum. Subsequently quarter of a grain of nitrate of silver and half a grain of opium every four hours. At times the patient complained of excessive pain in the upper third of the left thigh, but could move the hip-joint on the affected side without any pain or inconvenience. July 11th: An abscess was detected in the anterior portion of the left thigh, about three inches below the anterior superior spinous process of the ileum. July 15th: Assistant Surgeon William F. Norris, U. S. A., opened the abscess, evacuating a quantity of thin fetid pus. ℞. Citrate of iron and quinia, four grains, three times daily; an ounce of sherry wine every three hours. In the evening there was high fever and profuse perspiration. July 16th: The discharge still continues; the fever and sweating have increased. July 21st: ℞. Aromatic sulphuric acid, five drops, every three hours. July 22d: The diarrhœa is worse. July 26th: Had eight stools in the last twenty-four hours, accompanied by dysenteric symptoms. July 28th: Is losing strength; countenance sharp; profuse perspiration. July 29th: Ten stools. August 1st: Delirious. Died, August 3d, at 3.30 A. M. *Autopsy* ten hours after death: Body excessively emaciated. The abscess was found to extend to the exterior of the capsule of the left hip-joint. There were slight pleuritic adhesions on both sides, apparently of recent date. The lungs were healthy. The liver fatty. The spleen enlarged and softened. The kidneys normal. Peyer's patches were very visible. The rectum was ulcerated, the ulcerations varying from the size of a pea to that of a large almond. The mucous membrane was thickened.—Acting Assistant Surgeon Carlos Carvallo.

CASE 327.—Private Arnold Gelhouse, company H, 37th Wisconsin volunteers; age 44; admitted from the field hospital of the 9th Army Corps, July 25, 1865. Chronic dysentery. In this case the most noticeable symptoms were distressing tenesmus and a very rapid pulse from the beginning. Eight grains of subcarbonate of bismuth and one of opium, to be taken every three hours, were ordered at first, but with little benefit. Opium suppositories were next resorted to, which somewhat lessened the pain and tenesmus, but did not check the frequency of the stools. Injections of nitrate of silver, two grains to the ounce of water, four times a day, were next directed, with some relief to the patient; but his strength gradually gave way, the abdomen became tympanitic, breathing labored, and he died, August 7th, at 12.30 A. M. *Autopsy* twelve hours after death: There were numerous old pleuritic adhesions on both sides. The lungs and heart were healthy. The spleen was of natural size, but quite soft. The small intestine was nearly normal. The large intestine was ulcerated from one end to the other; the mucous membrane of the rectum was almost entirely destroyed, only a few shreds remaining. Just below the sigmoid flexure there was a perforation half an inch in diameter; although there were no signs of fæces having escaped into the abdominal cavity, there was considerable peritonitis around the perforation and in the course of the colon generally.—Acting Assistant Surgeon George P. Hanawalt.

CASE 328.—Private William Mahar, company G, 10th United States infantry; age 19; admitted August 26, 1865. Diarrhœa. The patient was quite weak and pale. He stated that he had a chill two or three days previously, but none since. He had suffered from diarrhœa for some days, with from four to eight watery stools in the twenty-four hours. The order for his admission stated his disease to be typhoid fever, but no evidences of that disorder were observed. The pulse at his wrist counted 44, but an intermediate beat was heard over the heart; there was some slight abdominal pain, but no tenderness on pressure in the right iliac region; there was no delirium; his tongue was clean, moist, and slightly reddened; he complained of thirst. Ordered pills of nitrate of silver and opium, and a mixture of quinine and muriatic acid. August 28th: Pulse 64, heart-beat normal; the other symptoms are unchanged. The patient remains quite rational. August 29th: At 9.30 A. M. I was

called to see him, with the intelligence that he had a fit. I found him cold; his pulse weak; respiration infrequent; face pale; eyes wide open and turned upward; pupils very much dilated; corners of mouth twitching—*risus sardonicus*. I attempted to rouse him, and asked what is the matter? He replied, I don't know, and in a moment expired. Artificial respiration was attempted, with no result. *Autopsy* five hours after death: No rigor mortis. The lungs were healthy. The left side of the heart was firmly contracted, the right greatly distended with blood. The pericardium contained five or six drachms of serum. The liver, spleen, and kidneys congested, but otherwise normal. The mucous membrane of the intestines was inflamed, but not ulcerated. The mesenteric glands were enlarged. There were no indications whatever of typhoid fever, and no satisfactory evidence of the cause of death. [It does not appear from the record that the head was examined.]—Acting Assistant Surgeon Henry Gibbons, jr.

CASE 329.—Corporal William A. Harper, company K, 2d New York heavy artillery; age 31; admitted October 4, 1865. Chronic diarrhœa, from which he had been suffering two months and a half. The patient was very weak and emaciated, and suffered from almost constant nausea. He had ten or twelve liquid discharges daily. Stimulants, subcarbonate of bismuth, nitrate of silver, creasote, lime-water and milk, &c., were tried without success. The patient was unable to retain food or medicine, whether administered by the mouth or rectum. October 13th: He complained of pain in the left side of the chest, which was found to be dull on percussion; on auscultation large crepitation was heard. Carbonate of ammonia was prescribed, but was rejected. Flannel cloths saturated with turpentine and alcohol were applied to the chest, but with little effect. Died, October 21st. *Autopsy* fourteen hours after death: Rigor mortis well marked; body much emaciated. The brain was not examined. The left pleural sac contained about six ounces of fluid in which a few shreds of lymph floated; there were both old and new pleuritic adhesions on this side. The posterior two-thirds of the inferior lobe of the left lung was pneumonic; the superior lobe almost entirely healthy, as was the whole right lung. The liver was apparently healthy. The spleen small and hard. The kidneys were normal. The small intestine was inflamed and congested, with small patches of ulceration scattered over its mucous surface; the solitary glands seemed to be the seat of most of the ulcers; Peyer's patches were slightly engorged. The large intestine was inflamed but not ulcerated. The mucous membrane of the stomach near the pylorus was ulcerated, the ulcers resembling those of the small intestine.—Acting Assistant Surgeon George P. Hanawalt.

The next ninety-six cases are from the case-book of LINCOLN HOSPITAL, Washington, D. C.; Surgeon Henry Bryant, U. S. V., in charge from the date of the first case to May, 1863. After several temporary changes, Assistant Surgeon Roberts Bartholow, U. S. A., took charge from August 21st to December, 1863, when he was relieved by Surgeon J. Cooper McKee, U. S. A., who was still in charge at the date of the last case. In twenty-eight of the cases the autopsies were made and reported by Assistant Surgeon George M. McGill, U. S. A.; in thirty-nine, by Assistant Surgeon Harrison Allen, U. S. A.;* and in seventeen, by Acting Assistant Surgeon H. M. Dean.

CASE 330.—Private William S. Fetely, company B, 121st New York volunteers; admitted January 2, 1863. Typhoid fever. Died, January 12th. *Autopsy* six hours after death: The right lung was normal; the lower lobe of the left lung was in the state of gray hepatization; the upper lobe was congested; there was a considerable quantity of serous effusion in the left pleural cavity. The heart was normal, but contained a very large and tenacious clot. The small intestine was normal. The rectum was contracted and its walls were thickened. The liver was normal, except that in the inferior part of the left lobe there was a small calcareous deposit. The spleen was normal. The kidneys were large.—Assistant Surgeon George M. McGill, U. S. A.

CASE 331.—Private H. M. Foster, company A, 142d New York volunteers; admitted December 30, 1862. Typhoid fever. Died, January 13, 1863. *Autopsy* twenty-four hours after death: There were tuberculous deposits throughout the substance of the right lung, especially in its middle lobe, which was also much congested; the upper lobe of the left lung contained tuberculous deposits; the lower lobe was in the stage of red hepatization. The heart, liver, spleen, pancreas, and kidneys were normal. The jejunum and ileum were congested at irregular intervals, the congested portions being contracted and thickened. The descending colon was so much contracted that its caliber was less than that of the small intestine. The mesenteric glands were enlarged and tuberculous.—Assistant Surgeon George M. McGill, U. S. A.

CASE 332.—Sergeant Daniel W. Lyons, company K, 145th New York volunteers; age 21; admitted January 11, 1863. The first notes were taken January 14th. The diagnosis at that time was typhoid fever; the usual symptoms of that disease were present, and the patient was delirious at times. There was no perceptible change until January 17th, when he complained of a severe pain in his chest. On percussion slight dulness was detected over the lower lobe of the left lung, but nothing abnormal was discovered by auscultation. He had a slight cough, with rusty-colored expectoration. The treatment was at first stimulant; on the appearance of pulmonary symptoms an expectorant mixture was ordered, with counter-irritation over the seat of pain. Died, January 19th. *Autopsy* one hour after death: There was some effusion in the subarachnoid space and

* September 14, 1864, Dr. Allen presented to the Pathological Society of Philadelphia a brief "*Synopsis of Autopsies made at Lincoln General Hospital*," to which the reader is referred.—(Proceedings of the Pathological Society of Philadelphia, in the American Journal of the Medical Sciences, January, 1865, page 133.) In this paper he analyzes the appearances observed in forty-one cases of diarrhœa and dysentery, thirty-five of fever, twenty-one of pneumonia, and five of diphtheria. The notes of Dr. Allen's autopsies, from which the accounts here presented have been condensed, were not contained in the case-books of Lincoln hospital turned in to the Surgeon General's Office at the close of the war, but have since been copied into them from the originals, loaned for the purpose.

in the lateral ventricles. Strong adhesions were found on the anterior surface of the right lung; the right lung weighed eighteen ounces and a quarter, the left thirteen ounces and a half; the lower lobe of the left lung was congested hypostatically and presented a circumscribed region of hepatization; stellate spots of black pigment were scattered through the upper lobe. The heart weighed eight ounces and a half. The spleen weighed seventeen ounces and a half and was of a dark-purple color. The liver was pale and weighed seventy-four ounces. The kidneys weighed five ounces and three-quarters each. Ulcerations were observed on the transverse rugæ of the jejunum. The colon was contracted. The mesenteric glands were greatly enlarged.—Assistant Surgeon George M. McGill, U. S. A.

CASE 333.—Private Hiram H. Ames, company G, 78th New York volunteers; age 37; admitted January 11, 1863. Chronic diarrhœa of some six months' standing. The patient was very weak and much emaciated; he complained but little; the stools averaged about six daily. Died, January 20th. *Autopsy* twenty-two hours after death: There was slight effusion in the subarachnoid space; the veins of the pia mater were full. The brain weighed fifty-four ounces. The right auricle and ventricle of the heart contained large, firm, white fibrinous clots; the left ventricle a small clot of the same character. Throughout the right lung there were circumscribed condensations of tissue, apparently the result of inflammation, presenting the features of red and gray hepatization; these varied from the size of a pea to that of a large walnut; when excised they sank in water; the left lung contained only one area of condensation, which was found in its upper lobe; both lungs were full of blood; they weighed nineteen ounces each. The liver was full of blood; it was firm and had a granular appearance; the gall-bladder was small, the bile dark and viscid. The spleen weighed four ounces and a quarter; the pancreas three ounces and a half. The left kidney weighed six ounces and a quarter, the right six ounces. The mesenteric glands were large. The stomach was irregularly congested, its mucous membrane soft. The mucous membrane of the middle third of the jejunum was slate-colored; the valvulæ conniventes of the jejunum indistinct. The mucous membrane of the lower third of the jejunum and of the ileum was reddened and very soft; the intestinal walls were extremely thin; just above the ileo-cæcal valve the redness was more intense, attaining a brilliant purple color, and some gray patches of pseudomembrane adhered to the surface. Large numbers of ulcers were found throughout the large intestine, some of them rather indistinct, others with very sharp edges; they were of very irregular form. The mucous surface of the rectum presented a honeycombed appearance, and was coated with gray pseudomembrane. The whole large intestine was thickened.—Assistant Surgeon George M. McGill, U. S. A. [Nos. 154 and 155, Medical Section, Army Medical Museum, are from this case. The specimens are two successive portions of the thickened colon, with adherent patches of pseudomembrane on the mucous surface and a number of follicular ulcers.]

CASE 334.—Private Michael Murray, company K, 1st United States artillery; admitted December 29, 1862. Chronic diarrhœa. The patient, when admitted, had also cough, thirst, and typhoid symptoms. January 12th: Troublesome hiccough set in. Died, January 20, 1863, at 6 P. M. *Autopsy* twenty-one hours after death: The brain weighed forty-six ounces and a half. The lower lobes of both lungs were congested posteriorly, and in parts could not be inflated; the right lung weighed twenty-three ounces, the left twenty-one ounces. The heart was empty, and weighed six ounces and a half. The liver weighed forty-two ounces; it was of a reddish-brown color and faintly mottled. The mucous membrane of the intestines was slate-colored and quite soft; in the ileum, cæcum, and ascending colon it was very thin; in the transverse and descending colon there were a number of ulcers. The rectum was not much diseased. The kidneys weighed five ounces and a half each.—Assistant Surgeon George M. McGill, U. S. A.

CASE 335.—Private Charles N. Blake, company B, 4th Vermont volunteers; admitted January 2, 1863. Chronic diarrhœa. Died, January 25th, at 8 A. M. *Autopsy* twenty-nine hours after death: Height five feet five inches; body somewhat emaciated; the abdomen was discolored, and there were purpuric spots on the front of the chest. The brain weighed fifty-two ounces; it was light colored and of normal consistence; the choroid plexuses pale; the pons and medulla congested; the sinuses of the dura mater full of coagulated blood; the subarachnoid space contained a considerable quantity of liquid. Both lungs contained miliary tubercles, and in places masses of cheesy tubercle, especially in the lower lobe of the left lung; in the same lobe there was a large cavity which communicated anteriorly with a bronchial tube of the third magnitude; the right lung weighed thirteen ounces, the left twenty ounces and a quarter. The heart weighed four ounces and a quarter; its muscular tissue had a somewhat gelatinous appearance; the right and left ventricles each contained a small clot; there was very little fat about the heart; the lining membrane of the aorta was reddened as far as its bifurcation; the bronchial glands were much enlarged, white internally, and contained pus in places. The liver weighed forty ounces; scattered throughout its substance were numerous miliary tubercles; the bile was dark colored and viscid; there was a considerable deposit of tuberculous matter upon the under surface of the diaphragm immediately above the right lobe of the liver. The spleen weighed seven ounces; it was of a light reddish-brown color, and contained numerous miliary tubercles. The right kidney weighed five ounces and a quarter, the left kidney five ounces; both kidneys contained tubercles, especially in their lower portions. The pancreas weighed two ounces. The mesenteric glands were slightly enlarged, and some of them were tuberculous. The stomach was large; its mucous membrane soft near the pyloric orifice. Numerous round, hard, small bodies were observed on the mucous membrane of the duodenum; some of them were translucent; the mucous membrane was of a pale purplish color. In the upper part of the jejunum was a small white body a line in diameter, which was surrounded by a reddish areola; other similar white bodies occurred farther down; Peyer's patches were dotted with black pigment; the solitary glands were enlarged and hard; the ileum was red, congested, and presented extravasations of blood into its mucous membrane. In the large intestine the mucous membrane was very thin, and there were several dark congested patches in the rectum.—Assistant Surgeon George M. McGill, U. S. A.

CASE 336.—Private Alpheus D. Northrup, company G, 37th Massachusetts volunteers; admitted January 2, 1863. Chronic diarrhœa. Died, January 28th. *Autopsy* ten hours after death: Height five feet ten inches; body greatly emaciated; the blood was fluid. The brain weighed forty-three ounces; it was of a light color and firm consistence; there were firm pleuritic adhesions on both sides. Both lungs were quite full of blood; the right lung weighed seventeen ounces and a half;

there was a slight deposit of tubercles in its upper lobe; the surrounding lung-tissue was tough and partially solidified; the inferior lobe was intensely congested and partly hepatized; portions sank in water. The left lung weighed thirteen ounces and a half; the posterior part of its lower lobe was in a state of atelectasis, and several of the lobules were consolidated. The heart weighed five ounces and a half; its substance was very flabby and of a deep-red color; the left auricle contained a small fibrinous clot; the other cavities were empty; the pericardium contained half an ounce of clear serum. The liver weighed thirty-five ounces and a half; it was full of blood, rather soft, and faintly mottled; the gall-bladder was small and filled with dark viscid bile. The spleen weighed three ounces and three-quarters; it was decidedly tough. The pancreas weighed two ounces. The right kidney was pale, and weighed three ounces and a quarter; the left kidney weighed four ounces and a quarter; the base of its pyramids was congested. The mucous membrane of the stomach was thin. There were several patches of congestion, almost resembling ecchymosis, in the lower portion of the jejunum; its mucous membrane was thin; in the upper part of the ileum the mucous membrane was thin and easily scraped off. On the mucous membrane of the upper part of the large intestine there were patches of a whitish exudation, which, farther down, covered the whole surface; still lower down there were numerous irregular, nearly circular, ulcers, surrounded by zones of white granular matter; the rectum was dark-colored, and presented numerous black spots in which were other ulcers; the adjacent surface was frosted with granules of white fibrinous matter.—Assistant Surgeon George M. McGill, U. S. A.

CASE 337.—Private Alonzo D. Snow, company D, 137th New York volunteers; admitted from regimental hospital at Fairfax Station, Virginia, January 18, 1863. Chronic bronchitis. This patient was very much debilitated and had constant diarrhœa. Died, February 1st. *Autopsy* three hours after death: There was considerable post mortem rigidity, although the body was still warm. The brain weighed forty-six ounces and a half; there was a small quantity of pus in the lateral ventricles; the superficial veins were full of dark blood; the substance of the brain was of a dark color and soft. The right pleural sac contained about a pint of dirty yellowish liquid. The right lung weighed fifteen ounces and a quarter; its superior lobe was marked by a deposit of melanic matter following the course of the ribs; the middle lobe was congested anteriorly; scattered through the parenchyma of the lower lobe were a number of small irregular vomicæ containing a puruloid fluid; these cavities apparently did not connect with the bronchial tubes; in some cases bronchial tubes were found passing through them and surrounded by their contents without opening into them; the bronchial tubes contained a considerable quantity of frothy muco-pus; the left lung weighed twelve ounces and a quarter; there was some congestion in both lobes, and melanic matter in irregular patches at the apex. The pericardium was closely adherent to the surface of the heart. The tissue of the heart was firm and red; the right auricle was completely occupied by a dense black and white clot; in the right ventricle there was a pyramidal fibrinous clot, which extended into the pulmonary artery; the left ventricle also contained a small clot. The liver weighed fifty-eight ounces; it was of a uniform dark color externally, internally it approximated the nutmeg appearance; the gall-bladder was filled with very light watery bile. The spleen weighed six ounces and a half; it was somewhat softened and much congested; its color a very dark purple. The pancreas weighed two ounces and a half. The right kidney weighed four ounces and a half, the left kidney five ounces and a half. There was considerable softening of the mucous membrane through the whole alimentary tract, so that it tore with ease under the finger-nail. The ileum was congested at irregular intervals; the spots were at first of a light-orange color, which subsequently changed to a dark-brown. The large intestine was congested and its mucous membrane softened.—Assistant Surgeon George M. McGill, U. S. A.

CASE 338.—Private C. R. Johnson, company B, 36th Massachusetts volunteers; admitted February 8, 1863. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 36th Massachusetts volunteers as admitted December 2, 1862—dysentery—returned to duty December 16th. He subsequently appears on the same register as admitted January 22, 1863—typhoid fever—sent to general hospital January 24th.] He walked into the ward carrying his knapsack, but appeared somewhat exhausted by the fatigue of the journey. During the afternoon he had several loose dejections, and one at midnight. He received ten grains of Dover's powder, and rested tolerably during the night. Next morning he complained of pain and soreness in the abdomen. The diarrhœa still continued. In the evening his symptoms were more urgent, the abdomen being somewhat tense and tender. Pills of blue mass and opium were prescribed. Died, February 10th, having just previously been out of bed to evacuate his bowels. *Autopsy* twelve hours after death: Height five feet seven inches; body not much emaciated; age apparently about 35 years; rigor mortis marked. The brain weighed forty-six ounces; it was of light color and normal consistence. The right lung weighed twenty-three ounces, the left eighteen ounces and a half; both lungs were congested and marked with pigment in bands corresponding to the ribs; a calcareous concretion was found at the apex of the left lung. The bronchial tubes were congested. The heart was firm and red; it weighed nine ounces and a half. The semilunar valves of the aorta were thickened and their adjacent edges adherent to each other. There was a large fibrinous clot in the right side of the heart, none in the left. The peritoneum was extensively inflamed. The liver weighed fifty ounces and a half; it was light colored, flabby, its acini distinct; the gall-bladder contained six drachms of very thick black bile. The spleen weighed three ounces and a half; it was soft, flabby, and of a dark-red color. The pancreas weighed two ounces and three-quarters; it was very light colored and firm. The right kidney weighed five ounces and a half, the left four ounces and a half; both kidneys were light colored and tough. The stomach was large. The valvulæ conniventes became indistinct in the lower portion of the jejunum, and the mucous membrane acquired a light slate color. The ileum was slate-colored and contracted. The colon was very much thickened and extensively ulcerated; one of the ulcers near the cæcum had perforated. The rectum was thick, soft, and readily torn, but not ulcerated. The bladder was hypertrophied.—Assistant Surgeon George M. McGill, U. S. A.

CASE 339.—Private David Fenstermaker, company K, 48th Pennsylvania volunteers; age 26; admitted from the hospital of the 2d Division, 9th Corps, Windmill Point, Aquia Creek, Virginia, February 8, 1863. Chronic diarrhœa, contracted at Fredericksburg. He had been sick a month, was emaciated, and had twelve to fifteen evacuations daily. His tongue was dry and brown, his features shrunken, and there was slight tenderness over the abdomen. ℞. Mercury with chalk, ten grains,

tannic acid two grains, quinine six grains; make eight pills. Take one every two hours. Half an ounce of brandy every hour. February 9th: Much the same; diarrhœa slightly less. February 10th: Diarrhœa worse again; stools involuntary. Died, February 11th. In this case the use of beef-tea seemed to aggravate the diarrhœa.—Acting Assistant Surgeon Daniel Weisel. *Autopsy* two hours after death: Height five feet ten inches; no rigor mortis; body somewhat emaciated. The brain weighed forty-eight ounces and a half; it was light-colored and soft; the pia mater was somewhat congested. The right lung weighed thirty-five ounces and a quarter, the left forty-eight ounces and a half; the right lung was congested throughout and presented a number of isolated hepatized lobules; the central portion of the upper lobe of the left lung and an irregular area in the lower lobe were also in the state of red hepatization; the rest of the lung was congested; the bronchial tubes on both sides were inflamed, the bronchial glands large and black. The heart weighed eight ounces and a quarter; its muscular tissue was firm and red; there was but little surrounding adipose tissue; the right cavities contained black clots which weighed an ounce and a quarter. The pericardium contained an ounce of serum. The liver weighed fifty-nine ounces and a half; it was firm, finely mottled, and generally congested; the gall-bladder contained a small quantity of light-yellow viscid bile. The spleen weighed eleven ounces and a quarter; it was of a dark-purple color, very firm and congested, its trabeculæ indistinct. The pancreas weighed two ounces and three-quarters; it was light-red and firm. The suprarenal capsules were normal. The right kidney weighed nine ounces, the left nine ounces and a half; the cortical substance of both kidneys had a peculiar light flesh color; their capsules were very readily torn off. The stomach was rather large, its mucous membrane soft. The mucous membrane of the small intestine was reddened; the valvulæ conniventes very distinct. The ascending colon was dark colored; its mucous membrane soft; its glands distinct and slightly enlarged; the transverse colon was contracted; its mucous membrane slate-colored, thin, soft, and presented a number of small ulcers; the descending colon was dilated; but, with this exception, presented the same appearances as the transverse colon. In the sigmoid flexure and rectum the ulcers were still larger and more numerous.—Assistant Surgeon George M. McGill, U. S. A.

CASE 340.—Private Alexander R. Bowser, company B, 139th Pennsylvania volunteers; age 26; admitted January 2, 1863. Diarrhœa. The patient had been sick ten days and was much reduced. The stools numbered eight to ten daily and were very thin and watery. He had no appetite; the tongue was dry; there was little or no abdominal tenderness. ℞. Blue mass thirty grains, ipecacuanha and opium of each two grains; make ten pills. Take one every two hours; on alternate hours ten grains of chlorate of potassa. Beef-tea, wine-whey, brandy. January 11th: The number of stools has been reduced to three or four daily, and are more consistent; the tongue is moister and shows some tendency to clean; the appetite has improved somewhat. January 22d: There are now two stools daily; the tongue is quite moist and clean. January 28th: The diarrhœa has returned with increased severity without any apparent cause. January 30th: The diarrhœa is no better; he complains for the first time of pain in the abdomen; the tongue is dry and brown; sordes on the teeth and gums. Typhoid fever was diagnosticated. Ordered stimulants and beef-tea to be given freely, also ten grains of chlorate of potassa every two hours. February 2d: The patient is much reduced; the diarrhœa but little better; the abdominal pain continues. Symptoms of pneumonia on the right side have made their appearance; there is considerable stupor, and he can scarcely be aroused to take nourishment. February 7th: There is great stupor; had fourteen involuntary stools last night. Died, February 13th, at 6.15 A. M.—Acting Assistant Surgeon Daniel Weisel. *Autopsy* fourteen hours after death: Height five feet eight inches; body emaciated and quite rigid. The brain weighed forty-nine ounces and a half; it was light colored and soft. The right lung weighed thirty-six ounces and a quarter, the left twenty-two ounces and a quarter; there were a number of cretefied tubercles in each; the middle lobe of the right lung was congested, the lower lobe hepatized, partly red, partly gray; the anterior portion of the upper lobe of the left lung was slightly congested, the lower lobe very much congested; there was but little black pigment in either lung. The bronchial tubes on both sides contained pus; their walls were thickened and the caliber of the tubes increased. The heart weighed seven ounces and a half; its muscular substance was pale; there was but little adipose tissue about it; there was a black clot in the cavities of the right side, a white fibrinous clot in those of the left; the clots weighed an ounce; the pericardium contained an ounce of fluid. The liver weighed sixty-two ounces and a quarter; it was of a light yellowish brown color and considerably mottled superficially, its acini indistinct; there were numerous peritoneal adhesions between the liver and the parietes of the abdomen; the gall-bladder contained a small amount of thick yellowish bile. The spleen weighed nine ounces and a half; it was of a dark brick-red color, tolerably firm, its trabeculæ distinct; like the liver it was firmly bound to the adjacent parts by peritoneal adhesions. The pancreas weighed two ounces and a half; it was light colored and firm. The suprarenal capsules weighed three-fourths of an ounce; they were large, red, and tough, with thick whitish borders and hard centres. The kidneys were firm and slightly congested; in the lower part of the right kidney was a small cyst. The urinary bladder was empty. The cardiac extremity of the stomach was slightly congested. The upper two-thirds of the jejunum were congested, its lower third blackened; in the latter portion the mucous membrane was thin and the valvulæ conniventes indistinct. The ileum was distended and slightly congested, its solitary glands enlarged; a number of patches of exudation of a grass-green color were observed in the ileum; they were arranged transversely to the length of the gut and parallel to each other; the lowest of them was three inches above the ileo-colic valve; it was quite granular in appearance; there were also a number of ulcers in the ileum which were surrounded by areas of congestion. The cæcum was intensely congested; its mucous membrane and that of the colon presented patches of pseudomembrane similar to those in the ileum, which increased in number and extent, until in the sigmoid flexure they formed an almost continuous coating to the mucous membrane. There were also a number of ulcers in the descending colon, sigmoid flexure, and rectum; many of them were coated with the pseudomembrane; when this was removed their bases were red and resembled granulations.—Assistant Surgeon George M. McGill, U. S. A.

CASE 341.—Private John Curdy, company E, 140th New York volunteers; admitted December 30, 1862. Typhoid fever. [This man appears on the register of the regimental hospital of the 140th New York volunteers as admitted November 14th—fever; no disposition recorded.] When the first notes were taken, January 24th, the patient was emaciated; pulse 95; severe cough; expectoration muco-purulent; bowels loose, three or four evacuations daily; appetite tolerably good. Treatment:

Nutritious diet, tonics, and astringents. Died, February 14th. His mind remained clear to the last. *Autopsy* three hours after death: Height five feet four inches; body somewhat emaciated; no rigor mortis; apparent age 28 years. The brain weighed forty-six ounces; it was of a light color and moderately firm. The right lung weighed twenty-eight ounces and a half, the left thirty-one ounces and a half; both were blackened externally by deposits of pigment, and contained abundant deposits of tubercles, many of which were softened; several large vomicæ were found in the upper lobe of each lung; the total capacity of these cavities was estimated at about twelve cubic inches; the remaining portion of the upper lobes was solidified. The bronchial tubes were congested, contained pus, and those leading from the solidified lobes were plugged with fibrinous exudation; extensive pleuritic adhesions, corresponding with the consolidated lobes, existed on both sides. The heart weighed seven ounces and a half; it was flabby and presented but little adipose tissue externally; the blood was fluid, but coagulated readily; the pericardium contained eight fluid drachms of a greenish-yellow fluid. The peritoneum generally was inflamed and slight adhesions had taken place. The liver weighed forty-eight ounces; it was of a dark brick-red color, firm, very faintly mottled, its acini rather indistinct; minute miliary tubercles were observed on its surface; the gall-bladder contained four drachms and a half of thin straw-yellow bile. The spleen weighed seven ounces and a half; it was of a blood-red color, firm, and contained miliary tubercles. The pancreas weighed three ounces and a half; it was of a light slate color and firm. The right kidney weighed four ounces and three-quarters, the left kidney four ounces and a quarter; both kidneys were firm and light colored; the right contained tubercles. The suprarenal capsules were of medium size, tough, and of an ochre color. The stomach was large; its mucous membrane thick and soft. The duodenal glands were enlarged. The mucous membrane of the small intestine was thin; the valvulæ conniventes indistinct, and disappeared in the lower part of the jejunum. The lower third of the ileum was congested, and the patches of Peyer in this region were ulcerated. Other ulcers, not seated in Peyer's patches, were situated as follows: In the upper part of the jejunum was a ragged ulcer, with a soft centre and raised sharply-defined edges; on the outside of the gut its situation could be detected by a moderately hard white ring corresponding to its internal edges. In the inferior third of the jejunum was a small ulcer on a raised base, surrounded by irregular congestion; viewed from the outside its situation was marked by a white spot. A similar ulcer, of medium size, occurred still lower down, and in the upper portion of the ileum were a number of small ulcers of the same general character. One ulcer in the lower third of the jejunum exhibited on the peritoneal surface a number of small white round masses supposed to be tubercles. The cæcum was congested and ulcerated, as was also the ascending and transverse colon; one large ulcer in the transverse colon measured two and a half by two inches; the mucous membrane of the rectum was slate colored; it presented a number of ulcers and some formations which were thought to be deposits of tubercle. The mesenteric glands were enlarged.—Assistant Surgeon George M. McGill, U. S. A.

CASE 342.—Private Aaron Bridge, company F, 13th New Hampshire volunteers; admitted February 8, 1863. Chronic diarrhœa. Died, February 14th. The patient was comatose for several days before his death; just before he died, however, the coma disappeared, and he was able to converse quite rationally. *Autopsy* thirty-three hours after death: Height five feet six inches; body emaciated; rigor mortis slight; apparent age 55 years. The brain weighed fifty-two ounces and a half; it was firm and of a pinkish color. The right lung weighed fourteen ounces and a half, the left eighteen ounces; there were some calcareous concretions in both lungs; some of the lobules of the upper lobe of the left lung were in a state of gray hepatization; its lower lobe was congested; some of the bronchial tubes leading from the consolidated lobules contained pus, others were plugged with fibrin. The heart weighed nine ounces and a quarter; there were fibrinous clots on both sides, which, together, weighed an ounce and a quarter; the pericardium contained some reddish-brown serum. The liver was firm, its acini distinct; it weighed fifty-three ounces and a half; the gall-bladder contained about three ounces of thin dark-green bile. The spleen weighed six ounces and a quarter; it was of dark color and natural consistence; its trabeculæ were distinct. The pancreas weighed two ounces and a half; it was soft and yellowish. The right kidney weighed five ounces and a half, the left five ounces; both were light colored, firm, and lobulated; the bladder was full of urine. The stomach was distended, its mucous membrane congested. The duodenal glands were somewhat enlarged. The ileum was distended; in the upper third its mucous membrane was intensely congested; its solitary glands were large, and a dot of black pigment appeared in the centre of each; Peyer's patches were large in the lower third of the ileum; they were not generally diseased, but some of them presented small ulcers, which in no case, however, involved the whole patch; moreover, some of the Peyer's patches appeared healthy; some of the solitary follicles were ulcerated. The solitary glands of the colon were enlarged, and presented central dots of pigment; the descending colon was slightly congested.—Assistant Surgeon George M. McGill, U. S. A.

CASE 343.—Private Henry Shomberg, company B, 54th New York volunteers; admitted February 19, 1863. Chronic diarrhœa. Died, February 22d, at P. M. *Autopsy* thirteen hours after death: Height five feet five inches; apparent age 28 years; body emaciated; some rigor mortis. A cleft palate was observed, and the cicatrix of an operation for hare-lip. There was a curvature of the spine to the left. The brain weighed fifty ounces; was light colored and of firm consistence. The right lung weighed thirteen ounces and three-quarters, the left eleven ounces; both lungs contained a large quantity of melanic matter, arranged externally in bands corresponding to the course of the ribs, internally following the blood-vessels; in the lower lobe of the left lung there was a calcareous mass the size of a pea; both lungs were congested. The heart weighed nine ounces and a half; there was much adipose tissue on its surface; two of the aortic valves were thickened and their free borders nodulated; on one of them was a firm red outgrowth the size of an apple-seed; on the anterior flap of the mitral valve there was an atheromatous patch; there were small white fibrinous clots in both ventricles; the pericardium contained a moderate quantity of fluid. The liver weighed sixty-two ounces and a half; it was pinkish-yellow, with indistinct acini, its capsule firmly adherent; the gall-bladder contained half an ounce of thin reddish-green bile; there were strong adhesions between it and the transverse colon. The spleen was light-brown and weighed nine ounces. The pancreas was pink, firm, and weighed three ounces and a quarter. The right kidney weighed eight ounces and a quarter, the left seven ounces and a half; each kidney contained a small cyst; the cortical substance of both was pale, the pyramids purplish-red. The stomach was irregularly congested, especially in its fundus; it was somewhat enlarged and its mucous membrane softened. The small intestine was somewhat dilated and very

thin, its mucous membrane quite soft. The solitary glands of the ileum were enlarged, conical, and white at their apices; several small dark-bordered ulcers, unconnected with Peyer's patches, were observed. The mucous membrane of the colon and rectum was congested; in the sigmoid flexure it was softened.—Assistant Surgeon George M. McGill, U. S. A.

CASE 344.—Corporal Hiram A. Scott, company A, 137th New York volunteers; age 23; admitted from regimental hospital, Fairfax station, Virginia, January 18, 1863. Typhoid fever. When admitted had frequent pulse, dry skin, and some cough. Dulness on percussion was observed on the right side of the chest. The expectoration was scanty at first, but subsequently became free. Died, February 23d. *Autopsy* fifteen hours after death: Height five feet seven inches; body emaciated; rigor mortis slight. The brain weighed fifty ounces; it was slightly congested and of a pale flesh color, its substance slightly softened; the subarachnoid space contained two ounces and a half of serum. The right lung weighed twenty-four ounces and a half, the left twenty-one ounces and a half; both pleural sacs contained serum, in all about three pints; both lungs contained much black pigment; the lower lobes of both were solidified, and the bronchial tubes leading to them inflamed. The bronchial glands contained much black pigment; three of them on the right side were somewhat enlarged. The heart weighed eleven ounces; firm white clots were found in both sides; they weighed two ounces. The liver weighed eighty-four ounces and a half; it was soft, and presented the nutmeg appearance; the gall-bladder contained six drachms of thin, dirty-yellow bile. The spleen weighed seven ounces and a half; was of a brick-red color internally, and tolerably firm; on its surface was a white fibrous band, by which the organ appeared somewhat constricted. The pancreas was firm, weighed three ounces, and was of a light straw-color. The right suprarenal capsule was large, the left small; they were of a dark coffee-color and tough. The right kidney weighed five ounces, the left five ounces and a quarter. The stomach was slightly larger than usual; its mucous lining was somewhat softened. The mucous membrane of the small intestine was soft; the edges of the valvulæ conniventes congested. The large intestine was distended and congested throughout its whole length. The mucous membrane of the rectum was soft, much discolored, and covered with pseudomembrane. The mesenteric glands were enlarged.—Assistant Surgeon George M. McGill, U. S. A.

CASE 345.—Private Alonzo Russell, company C, 7th Wisconsin volunteers; admitted February 19, 1863. Consumption. [This man appears on the register of the hospital of the 1st Division, 1st Army Corps, Windmill Point, Aquia Creek, Virginia, admitted January 18th—chronic diarrhœa—sent to general hospital February 18th.] On admission this patient was extremely exhausted. He was much emaciated, and complained of cough, and pain in both lungs and in the abdomen. The sputa were somewhat purulent, and mixed with blood. There was dulness on percussion below both clavicles, and mucous rales were heard on both sides of the chest. He had three or four loose evacuations daily; had but little appetite; the abdomen was tender on pressure. Stimulants and nourishing diet were directed. Died, February 25th.—Acting Assistant Surgeon E. E. Andrews. *Autopsy* sixteen hours after death: Height five feet eight inches; body emaciated, somewhat rigid; apparent age 28. The brain weighed forty-four ounces and a half; was light colored and soft. In two places, one on each side of the longitudinal sinus, the Pacchionian bodies had attained great size, producing absorption of the dura mater, internal table, and diploë. The right lung weighed seventeen ounces and a quarter, the left twenty-one ounces and a half; both were congested hypostatically; there was a tubercular deposit the size of a filbert in the anterior edge of the upper lobe of the left lung; another the size of a pea in the apex of the right lung. The bronchial glands were dark and hard. The heart weighed six ounces; it was firm, red, and contained no clots; the usual amount of adipose tissue was present. The pericardium contained an ounce of serum. The liver weighed thirty-six ounces; scattered through its substance were a number of miliary tubercles; two drachms of light-colored watery bile were found in the gall-bladder. The spleen weighed three ounces and a quarter; it was of a dark-brown color, firm consistence, and filled with tubercles. The pancreas weighed two ounces and one-eighth; it was dark colored and very firm. The suprarenal capsules were large and tough. The right kidney weighed four ounces and a quarter, the left four ounces and a half; they were very much congested. The stomach was congested almost to ecchymosis; its mucous membrane soft, the congestion and softening extending into the duodenum. The upper part of the jejunum was slate-colored; other portions of the intestinal mucous membrane were congested. The solitary and agminated glands were normal.—Assistant Surgeon George M. McGill, U. S. A.

CASE 346.—Private Ely Olp, company I, 135th Pennsylvania volunteers; admitted January 27, 1863. Chronic diarrhœa. This patient, when admitted, had ten or twelve evacuations daily; was extremely emaciated; tongue furred; pulse 80; no cough or expectoration noticed. Anodynes and astringents were given, which somewhat diminished the number of evacuations; the strength of the patient was supported by wine and ale; but the stools became very offensive and putrid, the appetite failed, and the patient gradually sank. Died, February 25th. *Autopsy* six hours after death: Height five feet five inches and a half; apparent age about 38 years; body much emaciated; no rigor mortis. The brain weighed forty-eight ounces and a half; it was of a light color, soft and flabby; there was but a small quantity of subarachnoid fluid. The right lung weighed thirteen ounces and a quarter, the left eleven ounces and a quarter; tuberculous deposits were found in all the lobes of both lungs, but especially in their apices; but little softening of these deposits had taken place; the surfaces of both lungs presented an excess of black pigment. The bronchial glands were large, firm, and black. The heart was firm, and weighed eight ounces; there was a large white clot in its right side, a mixed clot in the left; the clots weighed two ounces and a quarter. The pericardium contained six drachms of straw-colored serum. The mucous membrane of the œsophagus was softened and ulcerated for a space which extended from two inches below its commencement downward four inches; there were several separate ulcers, some of which were coated with a greenish disorganized substance. The liver weighed forty ounces and a half; it was mottled purple and white, the acini distinct; miliary tubercles were found in all parts; the gall-bladder contained two drachms of a watery light-brown bile. The spleen weighed three ounces and three-quarters; it was tough, firm, and light colored. The pancreas weighed three ounces and three-quarters; it was flesh-colored and firm. The suprarenal capsules were rather large, and together weighed a quarter of an ounce; they were of a dark coffee-color and tough; in the upper part of the left capsule there were two small cysts. The stomach was natural. The glands of the duodenum distinct. The mucous membrane of the upper third of the jejunum was black, that of the middle third green, the lower third greenish-red; the upper third of the ileum was congested;

the mucous membrane throughout the small intestine was soft; the solitary glands were swollen; Peyer's patches inflamed; within eight inches of the ileo-cæcal valve were a number of small light-colored ulcers with raised edges; the valve itself was blackened by pigment deposits. There was some congestion in the cæcum, but not much in the ascending colon; in the transverse and upper third of the descending colon there was irregular congestion, with ulceration, and deposits of pseudomembrane.—Assistant Surgeon George M. McGill, U. S. A.

CASE 347.—Private M. H. Wray, company H, 135th Pennsylvania volunteers; age 35; admitted February 19, 1863. Diarrhœa. This patient was sent to field hospital in Virginia several months ago with œdema of the legs; subsequently he had an attack of measles, and this was followed by diarrhœa. When admitted he was extremely emaciated, complained of pain and tenderness over the abdomen; had frequent stools; pulse scarcely perceptible; skin cold and cadaverous; tongue moist and free from any fur; feet cold. Died, February 25th. Treatment: Blue mass and opium, Dover's powder, &c. Diet: Boiled milk, toast and tea, beef-tea, brandy. *Autopsy* nineteen hours after death: Height five feet nine inches; no rigor mortis. The brain weighed fifty-five ounces and a half; it was full of blood, and the vessels of the pia mater were injected. The right lung weighed twelve ounces and a half, the left eleven ounces; both lungs contained an excess of black pigment, and were congested hypostatically. The heart weighed seven ounces and three-quarters, and contained mixed clots which weighed two ounces. The pericardium contained two ounces of fluid resembling mucilage of acacia. The liver weighed thirty-eight ounces, was full of blood, of a reddish coffee-color and firm consistence, the acini indistinct; the gall-bladder contained two drachms of a very viscid and dark-green bile. The spleen weighed two ounces and three-quarters, was of a dark-red color and normal consistence; it contained a small nodule of cheesy matter. The pancreas weighed two ounces and a half. The suprarenal capsules were very small and tough. The left kidney weighed four ounces and a quarter, the right four ounces; they were both very dark colored and tough. The stomach was slightly congested in the fundus and toward the pyloric orifice; its mucous lining was soft. The duodenal glands were slightly enlarged. The valvulæ conniventes in the duodenum and jejunum were not well developed; the upper part of the jejunum was congested, the lower part of a light slate-color; the solitary glands were enlarged; the mucous membrane of the ileum was soft and deeply congested, but both the solitary glands and the glands of Peyer appeared to be normal. The mucous membrane of the cæcum was soft and dark colored. Congested patches were noticed at the splenic and sigmoid flexures of the colon; in the latter the mucous membrane was brownish-red. Assistant Surgeon George M. McGill, U. S. A.

CASE 348.—Private Peter Manning, company B, 49th Pennsylvania volunteers; admitted February 19, 1863. Consumption. [This man appears on the register of the hospital of the 2d Division, 6th Corps, Windmill Point, Aquia Creek, Virginia, admitted January 20th—diarrhœa; no disposition recorded.] This patient was extremely emaciated and prostrate when admitted. He had a severe cough, with copious purulent expectoration; he was also suffering from diarrhœa, and had six or eight evacuations daily. His cheeks were flushed; pulse from 100 to 120; he complained of pain in both lungs, but especially in the left. Nourishing diet, wine, and anodynes were administered. Died, February 26th. *Autopsy* five hours and a half after death: Height five feet one or two inches; body much emaciated; rigor mortis marked; apparent age 30. The brain weighed forty-two ounces; it was light colored and quite firm; the veins of the pia mater were full of blood. The right lung weighed twelve ounces and a half, the left thirty-three ounces. The bronchial glands were large, soft, and black. The heart weighed seven ounces and a half; it was firm and dark-red; there was very little adipose tissue externally; there was a large, firm, black clot in the right auricle, and mixed clots in both ventricles; the clots weighed four ounces. The pericardium contained five ounces of purulent serum in which flakes of lymph floated. The liver presented the nutmeg appearance; it weighed fifty-nine ounces and a half; the gall-bladder was empty. The spleen weighed four ounces, was of a very dark-purple color and unusually firm. The pancreas was flesh-colored, firm, and weighed three ounces and a half. The suprarenal capsules were remarkably large, firm, and dark-brown internally. The right kidney weighed four ounces, the left four and a quarter; both kidneys were dark-red and firm. The fundus of the stomach was congested. There was an area of congestion in the middle of the jejunum, and patches of congestion in the ileum; the solitary follicles of the ileum were slightly enlarged, and two of Peyer's patches, one in the lower part of the jejunum, the other in the ileum, were thickened; the remaining Peyer's patches were healthy; in the vicinity of the thickened patches the intestine was contracted. There were a number of congested spots in the ascending and transverse colon. (The intestines were not examined until thirty-eight hours after death.)—Assistant Surgeon George M. McGill, U. S. A.

CASE 349.—Private Addison Bowley, company C, 3d Vermont volunteers; admitted January 2, 1863. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 3d Vermont volunteers, excused from drill on account of diarrhœa, November 12, 1862, and again December 1st; in hospital with diarrhœa December 10th—sent to general hospital January 2d.] This patient had been suffering from diarrhœa three months. He was of scrofulous diathesis; about 30 years old; had large prominent blue eyes and dark hair. The action of his heart was violent, suggesting hypertrophy of that organ, and he complained of a sense of oppression in the præcordia. Pulse small, at times almost imperceptible; countenance cadaveric. Died, February 27th, at 7 P. M.—Acting Assistant Surgeon Henry F. Condict. *Autopsy* twenty hours after death: Height six feet; body very rigid; no emaciation. The brain weighed fifty-four ounces and a half; it was light colored and firm; there was an unusual quantity of serum in the subarachnoid space and in the ventricles. The right lung weighed twenty-five ounces, the left twenty-one; six pints of serum were taken from the pleural cavities; all the lobes of both lungs contained miliary tubercles, which were most abundant in their posterior portions; the lower lobes were hypostatically congested. The bronchial glands were tuberculous. The heart was soft, flabby, and weighed ten ounces; it was surrounded by a moderate quantity of adipose tissue; the heart-clots weighed one ounce and a quarter. The pericardium contained eight ounces of serum. The liver weighed eighty-seven ounces; it was of a brownish-purple color, mottled, its acini distinct, and had miliary tubercles on its surface; the gall-bladder was empty. The spleen weighed twelve ounces and a half; it was of a dark-purple color, and had miliary tubercles both on its surface and internally. The pancreas weighed three ounces and a quarter. The suprarenal

capsules were large, soft, and coffee-colored. The right kidney weighed nine ounces and three quarters, the left eleven ounces and a half; both of them were light colored, friable, and slightly congested inferiorly. The stomach was large, its rugæ prominent. The mucous membrane of the duodenum was congested and softened. There was irregular congestion of the lower fourth of the jejunum, and the whole of the ileum, alternating with slate-colored patches. The valvulæ conniventes were indistinct; the mucous membrane thin; the solitary follicles enlarged. The large intestine was dilated, its walls thin, its mucous membrane bluish and softened. There were several ulcers, each about the size of a three-cent piece, in the colon and rectum. On the peritoneal surface of the intestines were numerous miliary tubercles, which were particularly conspicuous in positions corresponding to the patches of Peyer.—Assistant Surgeon George M. McGill, U. S. A.

Case 350.—Private John C. Claus, company B, 43d New York volunteers; admitted February 24, 1863. Chronic diarrhœa of four months' duration; he had also a gunshot wound of the left foot, received at Fredericksburg. He was exceedingly emaciated, and had from two to four loose stools daily. Died, February 28th.—Acting Assistant Surgeon Daniel Weisel. *Autopsy* thirty-eight hours after death: Height five feet six inches; no rigor mortis; body very much emaciated. The brain weighed forty-eight ounces and a half; it was firm, injected with blood, the ventricles full of serum; there were old pleuritic adhesions on both sides. The lobes of the lungs were interadherent; the right lung weighed eighteen ounces, the left sixteen; posteriorly all the lobes of both lungs were intensely congested. The bronchial glands contained a great deal of black pigment. The heart weighed five ounces and a half; it was soft and flabby; there was no adipose tissue about it. The pericardium contained no fluid. The liver weighed thirty-nine ounces; it was dark-brown, firm, its acini indistinct; the gall-bladder contained two drachms of reddish viscid bile and a gall-stone quarter of an inch in diameter. The spleen weighed three ounces and a quarter; it was purple, friable, intensely congested inferiorly, its trabeculæ indistinct. The pancreas was of a dark slate-color, and weighed one ounce and three-quarters. The suprarenal capsules were large, tough, and of a dark coffee-color. The kidneys weighed four ounces each; they were dark colored, tough, and congested inferiorly. The rugæ of the stomach were indistinct. The jejunum was of a reddish slate-color; in its middle third a few inches of the tube were extremely dilated and very thin; the ileum was deeply congested. There were numerous ulcers, varying from the size of a pin's head to that of a half dime, in all parts of the large intestine; they were largest and most abundant in the sigmoid flexure and rectum; these ulcers, in the colon, were chiefly arranged in rows corresponding to the longitudinal muscular bands; many of them penetrated to the muscular coat.—Assistant Surgeon George M. McGill, U. S. A.

Case 351.—Private Smith Austin, company H, 33d New York volunteers; admitted February 20, 1863. Chronic diarrhœa. [This man appears on the register of the hospital of the 2d Division, 6th Army Corps, Windmill Point, near Aquia Creek, Virginia, admitted January 18th—diarrhœa; no disposition recorded.] He had been sick for five months. He was feeble, emaciated, his abdomen tender, and he had from six to eight loose passages daily. Ordered tonics and supporting treatment. February 26th: Symptoms of pneumonia in the right lung made their appearance. Died, March 2d, at 6 A.M.—Acting Assistant Surgeon Daniel Weisel. *Autopsy* eighteen hours after death: Height five feet seven inches; body emaciated; no rigor mortis. The brain weighed fifty-one ounces and a half; it was dark-gray and soft; the third and fourth ventricles contained an unusual quantity of serum; some sand-like granules were found in the pineal gland. The right lung weighed twenty-five ounces and a half, the left twenty-one ounces and a half; there were old pleuritic adhesions on both sides, which were very numerous on the left side; there was some lobular pneumonia in the posterior part of the middle lobe of the right lung, and a patch of red hepatization in the lower lobe; both these lobes were considerably congested, as was also the lower portion of the left lung. The bronchial tubes leading to the lower lobes of both lungs were also congested. The bronchial glands were of normal size but dark colored. The heart weighed nine ounces and a quarter, the clots three-quarters of an ounce; there was but a small amount of adipose tissue on the surface of the heart; there were several fibrous adhesions between the posterior wall of the left ventricle and the pericardium. The liver weighed forty-three ounces and a half; it was reddish-brown, tinged with slate-color, and quite firm; the gall-bladder contained nineteen drachms of yellowish, very viscid bile. The spleen weighed seven ounces; it was firm and of an irregular purplish slate-color, its trabeculæ well marked. The pancreas weighed two ounces and a half; it was firm and of a reddish slate-color. The suprarenal capsules were tough, light colored, and together weighed half an ounce. The kidneys were lobulated, and weighed four ounces and a half each; they were friable, slightly congested, and of a purplish-red color. The stomach was normal. The duodenal glands were large and distinct. The jejunum was quite thin, irregularly congested, and near the ileum dark slate-colored. The mucous membrane of the ileum was also slate-colored, and easily scraped off with the finger-nail. Peyer's patches were distinct and yellowish. There were a few ulcers in the cæcum and ascending colon, and a number of small black spots with whitish centres, which, when pressed, exuded a gelatinous substance; in the transverse colon there were numerous small ulcers with whitish borders, coated over with whitish lymph; there were also several ulcers in the sigmoid flexure and rectum.—Assistant Surgeon George M. McGill, U. S. A.

Case 352.—Private Peter W. Homer, company F, 1st New Jersey cavalry; age 26; admitted January 2, 1863. Typhoid fever, contracted a month previously at Fredericksburg. The patient was very much reduced, emaciated, had an exhausting diarrhœa, from ten to twelve thin watery evacuations daily, and much abdominal tenderness. Was ordered tonics, stimulants, and nourishing diet. January 15th: Some slight improvement is noticed; there are but six evacuations in the twenty-four hours. January 20th: Diarrhœa still better. The abdominal tenderness is subsiding, but erysipelas has set in. The eruption extended over the face and a portion of the scalp, but disappeared in the course of a few days, after which the diarrhœa grew worse again, there being about ten evacuations daily. The patient became exceedingly weak, could be aroused with difficulty, and his death was almost hourly expected till February 2d, when he began again slowly to improve. By the 15th the evacuations were reduced to one or two daily; they were of greater consistence, and he began to gain appetite and strength. February 24th: Is not so well; ate no breakfast; the diarrhœa is again troublesome; tongue furred. February 25th: Pneumonia was recognized: there was much cough, pain in the chest, and rusty sputa. Died, March 2d, at 10 P.M.—Acting Assistant Surgeon Daniel Weisel. *Autopsy* twenty-six hours and a half after death: Height five feet five inches and a half; body rigid and emaciated. The brain

weighed forty-eight ounces; it was very firm, of a grayish color, its blood-vessels injected. The right lung weighed twenty ounces, the left seventeen and a half; there was but little pigment in either; the lower lobe of the right lung was hepatized; the middle lobe and the lower lobe of the left lung were affected by lobular pneumonia. The bronchial glands were of normal size and dark color. The heart weighed nine ounces and a quarter; was quite firm; there was but little adipose tissue about its base; there was a white fibrinous clot in the right auricle and ventricle, which extended into the pulmonary artery; in the left cavities there was a similar clot, which extended into the aorta; these clots weighed eight ounces and three-quarters. The pericardium contained five drachms and three-quarters of serum. The liver weighed fifty-two ounces; it was firm, irregularly mottled, its acini indistinct; the gall-bladder contained six drachms of greenish-brown viscid bile. The spleen weighed five ounces and a half; it was moderately firm, of a dark-red color; its trabeculæ were distinct. The pancreas weighed two ounces and a half; it was flesh-colored and firm. The suprarenal capsules were large, yellowish, and rather friable. The right kidney weighed six ounces and a quarter, the left eight ounces and a half; both were light colored but firm. The mucous membrane of the fundus of the stomach was red; near the pylorus slate-colored; its rugæ were distinct. The duodenum was slate-colored and stained with bile; the jejunum slate-colored and slightly congested; the ileum was dark-yellow and congested in places; its lower portion had a smooth ironed look. The large intestine was of a dark slate-color and congested; the fæcal matter in it had a peculiarly offensive odor.—Assistant Surgeon George M. McGill, U. S. A.

Case 353.—Private Charles E. Edgely, company F, 13th New Hampshire volunteers; age 21; admitted February 18, 1863. Chronic diarrhœa. Had been sick three weeks, the symptoms being debility, chills, cough, and diarrhœa. When admitted he was much emaciated, but slept pretty well, and had a good appetite. February 20th: Pneumonia supervened. He had a slight chill, and took to his bed complaining of cough and excessive weakness; subcrepitant rales were heard on both sides; after a few days the rales on the right side were replaced by puerile respiration, on the left side by bronchial respiration and bronchophony. Died, March 7th. *Autopsy* nine hours and a half after death: The body was very rigid and slightly emaciated. The brain weighed fifty-two ounces and a half; it was firm and of a flesh color. On section the puncta vasculosa were quite conspicuous; the pia mater was congested; the subarachnoid fluid abundant. The right lung weighed twenty-two ounces and a quarter, the left thirty-eight and a half; the lower lobe of the right lung was very much congested; its upper lobe contained a few consolidated lobules. The right bronchial tubes were congested. There were extensive old pleuritic adhesions on the right side. The lower lobe of the left lung was in a state of gray hepatization; its substance was friable, and exuded pus on pressure. Recent pleurisy was manifested by false membrane covering the whole surface of the lower lobe, most of the upper, and binding the lobes together. The bronchial tubes proceeding from the hepatized lobe were obstructed by white fibrinous plugs. The heart was firm, its valves normal; in its right side was a firm fibrinous clot which extended into the pulmonary artery; a similar clot in the left side extended into the aorta; in the left side there were also some black coagula. The pericardium contained an ounce of light greenish-yellow serum. The liver weighed seventy-four ounces and a half; it was congested, firm, its acini distinct; the gall-bladder contained ten drachms of light straw-colored bile. The spleen weighed fifteen ounces; it was quite firm, and of a dark-purple color with whitish spots. The pancreas weighed three ounces and a quarter; it was quite full of blood. The suprarenal capsules were small, of a light coffee-color, and soft. The right kidney weighed six ounces and a half, the left seven and a quarter; both were pale, but firm. There was some congestion in the stomach, the mucous membrane of which was soft. In the upper part of the jejunum the mucous membrane was congested and of a dark-purple color; below, the congestion was irregular, and regions of apparently healthy mucous membrane were observed. The ileum was congested and distended with gas. Peyer's patches were slightly thickened and injected. The mucous membrane of the cæcum had a dark-purple color; the ascending colon was but slightly congested, the transverse colon intensely so, the descending colon appeared healthy; the rectum presented the same dark-purple congestion which was observed in the cæcum.—Assistant Surgeon George M. McGill, U. S. A.

Case 354.—Private Jacob Giles, company E, 14th United States infantry; age 20; admitted December 30, 1862. Chronic diarrhœa. The first notes were taken January 6, 1863, when the patient had suffered from diarrhœa for five months. He had bloody discharges and was troubled with piles at times. He was quite weak, thin, and pale, and had a dark-red tongue. January 10th: There were but three passages during the last twenty-four hours, and they were more natural. The patient thinks himself better, but is very much emaciated. February 2d: Still appears to improve. Croton oil mixed with tartar emetic has been freely applied to his abdomen for several days; the skin is very sore, but the pustules are imperfectly formed. He has about two painless passages daily. His appetite is returning. He complains at times of pain in the left shoulder and in the region of the spleen. Subsequently to this date the patient grew steadily feebler, though the stools seldom exceeded two daily. Croton oil was applied to his abdomen a number of times, but the skin seemed possessed of a singular resisting power. He died March 13th. It may be mentioned that during the first three weeks after admission the treatment of this case consisted in the administration of an emetic dose of ipecacuanha three times daily. *Autopsy* thirty-seven hours after death: Height five feet five inches; rigor mortis slight; body very much emaciated. The brain weighed fifty-three ounces; it was darker colored than usual, very full of blood, and quite firm; the vessels of the pia mater were not remarkably full; the commissura mollis was absent. The right lung weighed sixteen ounces and a quarter, the left twenty and a quarter; the lower lobe of the left lung and the posterior portion of the upper lobe were in a state of congestion bordering on hepatization; portions of the lower lobe readily sank in water, and much puruloid fluid issued from the section on pressure. The bronchial tubes of these lobes were congested in transverse lines. The lower lobe of the right lung was hypostatically congested; the remaining lobes normal. The bronchial glands were of the usual size, and black internally. The heart was flabby; it weighed, unopened, seven ounces; there was no adipose tissue on its exterior; the right ventricle contained a thin fibrinous clot. The pericardium contained four drachms of milky serum. The liver weighed thirty-nine ounces and a half; it was light reddish-brown, firm, its acini distinct; the gall-bladder contained fourteen drachms of light-yellow bile. The spleen weighed three ounces; was light-red, and firm; its trabeculæ were marked. There was a very small supplementary spleen. The pancreas was flesh-colored, firm, and weighed two ounces. The suprarenal capsules weighed together three-quarters of an ounce; the substance of the left was ash-colored, the right mottled

dark-purple and white. The right kidney weighed five ounces and a quarter; the left five ounces and a half; they were light-colored and firm. The mucous membrane of the stomach was normal, with the exception of a large patch of irregular congestion near the pylorus. The duodenal glands were large. The upper third of the jejunum was normal; in the middle third Peyer's patches were distinct; the mucous membrane presented irregular patches of arborescent congestion, and was frosted with pseudo-membrane; the same condition was observed in the ileum, which was more congested, and in its lower portion of a dark slate-color; Peyer's patches in the ileum had a mammillated appearance; the gut was very thin. In the cæcum and ascending colon the mucous membrane was brownish-red, and the granulated pseudomembranous frosting continued; in the transverse colon the pseudomembrane occurred in larger patches, which, when scraped off, exposed a reddened and abraded surface; farther down the patches became still larger, and covered a great portion of the surface; in the rectum, when the false membrane was removed, a blackish ulcerated base was found; two inches above the anus were three ulcers, each about one-third of an inch in diameter, with sharply cut edges, which extended to the muscular coat. The mesenteric glands were large and soft.—Assistant Surgeon George M. McGill, U. S. A.

CASE 355.—Private William Allerdist, company D, 20th New York volunteers; German; admitted January 2, 1863. Chronic diarrhœa and anasarca. Died, March 16th. *Autopsy* twenty hours after death: Height five feet four inches; body slightly emaciated; apparent age 28. The brain weighed fifty ounces and a quarter; there was some effusion in the sub-arachnoid space; in other respects the brain was healthy. The heart was small; it had very little adipose tissue about it; the valves were normal; the right side was filled with black clots. The pericardium contained a moderate quantity of fluid. Both lungs contained a considerable number of whitish cheesy tubercles; in the apices of their upper lobes these were surrounded with a considerable quantity of melanic matter; the lower lobes were congested and purplish on section. The bronchial tubes were congested and dilated; the larger tubes filled with a frothy mucoid serum. The right lung weighed twenty-two ounces and a quarter, the left twenty-three ounces and three-quarters. The liver weighed forty six ounces and a half; it was firm, full of blood, very finely mottled and smooth purplish-brown. The spleen weighed three ounces and a half; it was firm, full of blood, its trabeculæ distinct. The left kidney weighed eight ounces and a half, the right seven ounces; the cortical substance of the kidneys was ash-colored, the bases of the pyramids of a deep-blood color, the capsules separated readily. The suprarenal capsules were large, greenish-yellow internally, and very friable. In the interior of the left suprarenal capsule were several loose yellowish bodies of a fibrinous appearance. The pancreas was normal and weighed two ounces and a half. The stomach was large, its fundus congested. The mucous membrane of the duodenum was thin and soft; that of the jejunum was of a yellowish-ash color in its upper portion, purplish lower down; the ileum was dilated, its walls quite thin; all the patches of Peyer except the first were congested and dotted with black points. The cæcum was dilated and congested; the ascending colon at first presented a deep-purple color; farther up it was greatly contracted, of a deep-ash color with purple spots; the solitary glands had dark spots in their centres; the transverse colon was also much contracted; the descending colon, sigmoid flexure, and rectum were ulcerated; in the descending colon the ulcers were chiefly grouped along one of the longitudinal bands; they were of moderate size and had indistinct edges; in the sigmoid flexure they appeared as little pits, with indistinct edges, and were irregularly scattered over the mucous membrane; in the rectum they were of larger size, and quite irregular in shape.—Assistant Surgeon George M. McGill, U. S. A.

CASE 356.—Private George Shertle, company D, 48th Pennsylvania volunteers; admitted from the hospital at Windmill Point, Aquia Creek, Virginia, February 8, 1863. Chronic diarrhœa. Died, March 21st, at 12.30 A. M. *Autopsy* thirty-six hours after death: Height five feet seven inches; no rigor mortis; body extremely emaciated; apparent age 20. The brain weighed forty-three ounces and a half; the veins of the pia mater and of the brain were congested; the gray matter was darker colored than usual; the pineal gland was absent. The right lung weighed eleven ounces and three-quarters, the left seven ounces and a quarter; the posterior portion of the upper and middle lobes of the right lung was congested, the rest of the lung normal. There were old pleuritic adhesions on the left side. The left lung was collapsed, and some portions carnified. The larger bronchi contained a quantity of muco-pus. The heart weighed six ounces and a half; its substance was quite firm; there were white fibrinous clots in both sides; that in the left side extended into the aorta. The liver weighed forty-four ounces and a half; it was quite firm, and full of dark-colored blood; the gall-bladder contained six drachms of light-yellow watery bile. The right kidney weighed five ounces and a half, the left six ounces; in the right kidney, which was generally congested, were a number of white points the size of millet-seed, which upon section yielded a puruloid matter; in the upper part of the left kidney was an abscess the size of a hazel-nut, full of bluish-white pus; this kidney also contained small white purulent deposits similar to those in the right kidney, but not so numerous. The spleen weighed four ounces and a quarter; it was firm, of a reddish purple color, its trabeculæ distinct. The suprarenal capsules were dark-yellow and friable; the left capsule was quite large. The pancreas was dark colored, and weighed an ounce and three-quarters. The mucous membrane of the stomach was thin and congested. The duodenum was dilated, its glands large. The valvulæ conniventes of the jejunum were generally of a purplish color, while the rest of the mucous membrane was normal; the middle third of the ileum was intensely congested; in places there were extravasations of blood; Peyer's patches were well developed, most of them dark colored, and presenting a mammillated appearance. The mucous membrane of the cæcum and ascending colon presented a number of dark-purplish congested spots and ulcers of variable size, which were generally small and superficial; in the transverse colon, which was irregularly congested, there were but a few small ulcers; in the descending colon there were none; the ulcers were numerous in the sigmoid flexure and rectum, which were intensely congested.—Assistant Surgeon George M. McGill, U. S. A.

CASE 357.—Private James C. Hull, company H, 15th Connecticut volunteers; admitted February 8, 1863. Diarrhœa and debility. Died, March 26th. *Autopsy* eight hours after death: Height five feet five inches and a half; body very much emaciated; rigor mortis slight. The brain was quite firm, and weighed forty-six ounces and a half. The right lung weighed thirteen ounces, the left eight ounces; the posterior portion of the right lung was very much congested, the left healthy. The heart weighed seven ounces; its structure was firm; a mixed clot was found in the right side, none in the left. The liver

weighed thirty-three ounces and a quarter; its color was darker than usual; the gall-bladder contained from four and a half to five ounces of bile. The spleen was very firm, and weighed two ounces and a half. The pancreas weighed one ounce and a half. The right kidney weighed five ounces and a half, the left seven ounces and a quarter; both were of firm consistence. The rectum was ulcerated extensively and superficially, the ulcers being covered with a grayish-yellow pseudomembrane. The rest of the intestine was laid aside for examination, but was accidentally lost.—Assistant Surgeon George M. McGill, U. S. A.

CASE 358.—Private Stephen Chambers, company F, 145th Pennsylvania volunteers; admitted February 20, 1863. Diarrhœa and ascites. Died, March 30th. *Autopsy* two hours after death: Height five feet five inches and a half; body rigid and considerably emaciated. The brain was firm and weighed forty-seven ounces and three-quarters; there were several globular cysts in the choroid plexus, giving it a racemose appearance. The lungs were anæmic and bluish; there was slight lobular emphysema of the apex of the right lung, and in its posterior part a carnified spot which measured two inches by an inch, was of deep-purple color on section, and sank in water; a similar carnified spot was observed in the lower lobe, which was adherent posteriorly. The pulmonary pleura between the lobes was roughened by a number of minute whitish points of exudation. The upper lobe of the left lung was normal, but bound to the lower lobe by tough adhesions; its edge was also adherent to the pericardium; the right lung weighed fifteen ounces and three-quarters, the left fifteen and a quarter. The pericardium contained twenty-seven drachms of serum. The heart was flabby, its surface œdematous; there was no adipose tissue about it, and it contained no clots; the valves were healthy. The aorta presented several small whitish spots of atheroma just above the semilunar valves. The arteries of the body were filled with black blood. The abdominal viscera were agglutinated together and to the abdominal parietes by firm recent adhesions. The omentum was obliterated. The liver was congested, presented the nutmeg appearance, and weighed fifty-five ounces and a quarter. The spleen was rather firm, of a uniform dark-lake color on section, and weighed seven ounces and a quarter. The suprarenal capsules were rather dark colored. The right kidney was pale, of a light-ash color, its pelvis highly injected; it weighed five ounces; the left kidney was similar to the right, and weighed five ounces and three-quarters. The pancreas was normal, and weighed two ounces and a quarter. The mucous membrane of the œsophagus and stomach was pale; the duodenum yellowish; the jejunum of a stone-gray color; Peyer's patches were pale and inconspicuous; the solitary glands not observable; the summits of the villi, especially on the valvulæ, presented blackened points. The mucous membrane of the large intestine was of a dark-gray color; that of the rectum of a dark dirty red; the entire large intestine, externally, was irregularly coated with a greenish exudation of lymph. In the cæcum there was a ragged dark-green ulcer.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 359.—Private Charles Bufleb, company F, 14th Connecticut volunteers; admitted from Finley hospital, Washington, D. C., March 18, 1863. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 14th Connecticut volunteers, admitted January 15th—typhoid fever—sent to general hospital January 25th. He does not, however, appear on the register of the Finley hospital.] Died, April 3d. *Autopsy* one hour after death: Height five feet six inches; no post mortem rigidity; apparent age 30 years; there was diffuse suppuration of both parotid glands. The brain was firm, and weighed thirty-eight ounces and a half. The mucous membrane of the trachea was pale. The ramifications of the bronchi were filled with phthisical sputa. Miliary tubercles were disseminated through the right lung, most abundantly in its apex; on the surface of the upper lobe were long streaks of black pigmentary matter following the courses of the ribs; some of the lobules of this lobe were emphysematous, others carnified; the right lung weighed twenty-one ounces; its lobes were united together by recent lymph; the left lung was collapsed and presented nothing abnormal. The heart was pale; weight five ounces and a half; there was a good deal of adipose tissue on its external surface; there were no heart-clots. The aorta was slightly atheromatous just above the semilunar valves. The liver was purple externally, yellowish-purple internally; it weighed thirty-two ounces; the gall-bladder contained four drachms and a half of dark tenacious bile. The right kidney weighed seven ounces and a quarter, the left eight ounces; the cortical substance of both was pale, the pelves injected; the left kidney was rather darker colored than the right. The suprarenal capsules were large and dark colored. The spleen weighed three ounces; it was purple externally, light brownish-red internally, its texture firm. The pancreas weighed two ounces. The stomach was very small, the summits of its rugæ congested. The mucous membrane of the last five feet of the ileum was of a dark-purple color; Peyer's patches were normal, but in the neighborhood of the ileo-cæcal valve the solitary glands were tumefied. The mucous membrane of the large intestine was firm, generally dark colored, in some places purple; the solitary glands were numerous but healthy; there were no ulcers. The omentum was almost entirely void of fat, and extended to the pubis.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 360.—Private Walter Evans, company E, 111th Pennsylvania volunteers; age 21; in service twenty-three months; health previous to enlistment very good; admitted January 18, 1863. Chronic diarrhœa, from which he had suffered more or less for six months. He is anæmic, somewhat emaciated, and has about eight very copious evacuations daily of a thin gelatinous substance tinged with blood; the abdomen is tender. To take tincture of the chloride of iron, twenty drops, three times daily; also tannin and opium pills. To be confined to bed. Diet strictly farinaceous. This treatment was persevered in for about ten days, by which time he was much improved, the number of stools being reduced to three or four daily. The violence of the disease soon, however, returned after some slight imprudence, when he was put upon cod-liver oil, with tincture of the chloride of iron, and low diet. Solution of persulphate of iron and opium were subsequently tried, without any advantage; also the following: ℞. Extract of nux vomica eight grains, nitrate of silver two grains and a half, opium five grains; make ten pills. Take one every six hours. Under the influence of the last prescription the stools were again reduced to one or two daily, but the patient did not improve in strength or flesh. March 31st: He was suddenly seized with severe pneumonia. Died, April 3d.—Acting Assistant Surgeon Daniel Weisel. *Autopsy* thirteen hours after death: Height five feet five inches; rigor mortis moderate; some emaciation. The bronchial tubes were filled with a dark-purplish fluid. The upper lobe of the left lung was in the state of gray hepatization; on pressure a muco-purulent fluid exuded from its cut surface in large quantity; the lower part of the upper lobe and the upper part of the lower lobe of the right lung were hepatized, the rest of the lung congested; the right lung

weighed twenty-one ounces, the left twenty ounces. The heart weighed eight ounces; there was very little fat on its external surface; in the right auricle and ventricle was a firm fibrinous clot which extended into the pulmonary artery; in the left cavities was a similar but smaller clot which extended into the aorta. The pericardium contained six drachms and a half of fluid. The liver had the nutmeg appearance, and weighed seventy-five ounces and a half; the gall-bladder contained very little bile. The spleen was soft, of a dark-mulberry color, and weighed six ounces and a quarter. The left kidney weighed nine ounces and a half, the right eight ounces and a half; both kidneys were firm, their cortical substance of a light-pink color, the pyramids purple. The pancreas weighed three ounces. The stomach was dark colored, almost black in the fundus. The mucous membrane of the small intestine was firm and of a variegated pink; Peyer's patches were not enlarged, and the solitary glands were inconspicuous. The solitary glands were numerous in the cæcum and also in the vermiform appendix; the rest of the large intestine was of a dark-purple color mixed with red.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 361.—Private Albert Hopkins, company E, 89th New York volunteers; age 43; enlisted December 4, 1861; admitted February 8, 1863. Chronic diarrhœa. The first notes were taken April 1st. At that time the patient still suffered from diarrhœa. He said that he contracted the disease in September, 1862, and had not been free from it since. He had on an average four thin watery passages daily. He was weak and somewhat emaciated. There was marked tenderness on pressure over the abdomen, but no enlargement of the liver or spleen could be detected. His face was nearly covered with a pustular eruption resembling acne; his feet and legs were œdematous. On examination of the urine nothing abnormal was detected. The heart and lungs appeared to be healthy. His mind was disturbed, and at times he appeared to be perfectly demented. He was ordered to take, every three hours, a pill containing a grain and a half of acetate of lead and a grain each of opium and capsicum; also a laudanum enema at night. Farinaceous diet. April 7th: Has had but two passages in the past twenty-four hours; complains of severe pain in the loins. Ordered half an ounce of castor oil. Discontinue the pills until the oil operates. Also six dry cups over the seat of pain. April 16th: Since last date the patient has resumed the pills and seems a little better, but still complains of pain in the back. Continue treatment. Again apply six dry cups over the seat of pain. April 25th: I learned that he was in the habit of getting various kinds of indigestible food from the sutler; he was, therefore, confined to his bed. May 1st: The discharges from the bowels are nearly natural, and the patient is again allowed to sit up. May 7th: He was seized with severe pain in the loins, which was relieved by dry cups. May 8th: He had a return of the pain, which was not relieved by cups, but yielded to the influence of a large opiate enema. It was observed that his back was œdematous. May 9th: He had a severe epileptiform convulsion, preceded by retention of urine. The urine was drawn off by the catheter. On examination it was found to contain nothing abnormal. May 10th: He had four convulsions, and was delirious from this date until death. Died, May 16th, at 12.15 A. M.—Acting Assistant Surgeon G. K. Smith. *Autopsy* ten hours and three-quarters after death: Height five feet four inches; body rigid; no emaciation. The brain was apparently healthy; weight forty-five ounces and a quarter. The trachea and bronchial tubes, including the smaller ramifications, were filled with a fine bronchial secretion; the mucous lining was slightly injected. The upper lobe of the right lung was small and of a grayish color anteriorly; posteriorly it was congested; there were old adhesions at its apex, and the pigmentary deposit was rather abundant; the middle and lower lobes were also hypostatically congested. The left lung was congested posteriorly in a similar manner; on the surface of its lower lobe were numerous small ecchymosed spots. The heart was normal. The pericardium contained two drachms of fluid. The liver weighed sixty-nine ounces; there was a thin layer of recent lymph on its upper surface; on section it was of a pale flesh-color, its acini almost obliterated; the gall-bladder contained eleven drachms of ochre-colored bile. The spleen was six inches long and four inches wide, of a dull lake color and very soft. The pancreas was normal; it weighed two ounces and three quarters. The right kidney weighed seven ounces and a quarter, the left seven ounces and a half; the cortical substance of both was rather pale. The œsophagus was pale; the stomach slightly congested; the small intestine apparently normal. The large intestine was inflated with gas; its mucous membrane was slate-colored.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 362.—Private George Johnson, company H, 17th Mississippi infantry, (Confederate;) admitted May 13, 1863. Chronic diarrhœa. He was much emaciated and very weak. The motions were frequent, fluid, of a dark-green color and very fetid. His pulse was quick, compressible, and irregular; his skin hot; face flushed; tongue parched, smooth, covered with a brownish fur, and fissured; teeth and lips coated with nearly black sordes. He complained of pain in the chest, also of tenderness in the abdomen; wandered in his mind and was restless, being kept in bed with difficulty. He had at first a slight dry cough with a little frothy expectoration; this, however was soon changed, the cough becoming more violent, the sputa viscid and rusty, the breathing hurried, painful, and very difficult. On auscultation, bronchial respiration and bronchophony were heard on both sides. Treatment: Stimulants, tonics, anodynes, laudanum injections, and counter-irritation to the chest. Died, May 21st.—Acting Assistant Surgeon B. P. Brown. *Autopsy* eighteen hours after death: Body emaciated; some rigor mortis; height five feet ten inches and a half; apparent age 30 years. The brain weighed fifty-five ounces; was of firm consistence, and not congested. The œsophagus was natural, its mucous lining yellow. The lining membrane of the trachea was darkish green in color; it contained much bronchial secretion, and minute quantities of pus adhered between the cartilaginous rings. The lobes of the right lung were interadherent, and the whole lung was covered externally by recent lymph; on section the upper lobe appeared flabby, of a dark-reddish color, and contained a large quantity of black pigment; on pressure a fine bronchial secretion exuded; the middle and lower lobes were in a state of red hepatization, except parts of the lower lobe, which had advanced to gray hepatization. The upper lobe of the left lung was divided into three distinct lobes; its pigmentary matter was very abundant; the posterior part of this lobe was congested, and of a dark-purple hue; the lower lobe was hepatized, dark-purple, with much pigment externally, and coated by recent lymph; on section the hepatized tissue was of a purplish-red color; the right lung weighed fifty-two ounces and a half, the left thirty-eight and a half. The heart weighed twelve ounces and a quarter; its right side contained a large recent fibrinous clot which extended into the pulmonary artery; the lining membrane of the left ventricle had a dark tinge. A slight atheromatous deposit was observed in the aorta just above the semilunar valves. The pericardium contained an ounce of serum. The liver weighed seventy-one ounces; its parenchyma

was pale, the acini well defined; the gall-bladder contained an ounce of bile. The spleen was soft, and weighed ten ounces and a half. The pancreas was of normal color, and weighed four ounces and a half. The right kidney weighed ten ounces and a half, the left nine and a half; both kidneys were pale and flabby. The stomach was of a dark slate-color, tinged with ochre in the fundus, and pale near the pylorus. The small intestine was apparently healthy, of a pale color, and filled with pasty tenacious fæces; Peyer's glands and the solitary follicles were not conspicuous. The mucous lining of the large intestine was mottled of a pale-gray color, and coated in patches with a peculiar diphtheritic exudation, which was most prominent on the mucous folds; in some places there were superficial ulcerations. The intestines were moderately distended with flatus.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 363.—Private John A. Hopper, company E, 22d New Jersey volunteers; admitted April 19, 1863. Diarrhœa and pneumonia. [This man appears on the register of the regimental hospital of the 22d New Jersey volunteers, then near Belle Plain, Virginia, as admitted April 8th—typhoid-remittent fever—sent to general hospital April 18th.] Died, May 25th. *Autopsy* forty-seven hours after death: Height five feet eleven inches; some rigor mortis; skin dry and furfuraceous. The brain weighed forty-seven ounces and a quarter. The œsophageal mucous membrane was pale and soft; that of the trachea highly congested and soft. The upper and middle lobes of the right lung appeared on section of a deep reddish-purple color, and exuded a large amount of frothy bronchial secretion; they floated in water; the lower lobe was of a blackish-purple color, and presented emphysematous patches on its surface; it exuded a dark venous fluid, but little or no bronchial secretion; the left lung was similar in appearance to the right. The two pleural sacs contained six ounces and three-quarters of bloody serum. The heart weighed eleven ounces and a quarter; its right side contained a soft venous clot, the left ventricle a small white clot. The spleen was soft, pultaceous, and of a dark-lake color; it weighed twelve ounces and three-quarters. The liver was pale, its acini distinct; it weighed fifty-eight ounces; the gall-bladder contained seven drachms of bile. The pancreas weighed two ounces and a quarter. The right kidney weighed four ounces and a half, the left four and a quarter. The stomach was distended with gas; its mucous membrane blackish near the pylorus, the rest natural. The duodenum was much discolored by dark-purplish patches; the rest of the small intestine, except near the ileo-cæcal valve, was healthy; Peyer's patches were pale, not ulcerated or elevated; near the ileo-cæcal valve were numerous circular superficial ulcers penetrating to the submucous tissue; the solitary glands were prominent, but their contents were not blackish; those of the vermiform appendix were prominent. The large intestine was pale; a superficial ulcer of some size, with a blackish base, was found in the ascending colon; about eighteen inches from this was a smaller ulcer with ragged edges, and a short distance from this a third ulcer, not unlike the first, but more ragged. The intestines were distended with gas, especially the colon. The omentum contained very little fat.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 364.—Private William L. Snyder, company A, 12th United States infantry; admitted April 20, 1863. Chronic rheumatism. [This man appears on the hospital register of the 12th United States infantry, taken sick April 6th—diarrhœa—sent to general hospital April 19th.] Died, June 2d, of chronic diarrhœa. *Autopsy* twenty-four hours after death: Height five feet seven inches; body emaciated; rigor mortis slight. The brain was healthy and weighed fifty-four ounces. The mucous membrane of the œsophagus was firm and of a light-purple color. The trachea contained much bronchial secretion; its mucous membrane was purplish. Both lungs were pale stone-gray externally, lake-red on section, and yielded on pressure a fine bronchial secretion mixed with venous blood; they were permeated with air throughout; on the posterior surface of the lower lobe of the right lung was a small patch of old lymph; the right lung weighed nineteen ounces, the left twenty-four ounces. No fluid was found in the pericardium. The heart weighed nine ounces; in its right side was a very small fibrinous clot; in the left side large mixed clots which extended into the aorta; the valves were healthy. The liver weighed forty-five ounces; the gall-bladder contained six drachms of very dark-colored bile. The pancreas weighed three ounces and a quarter; it was healthy, and of a pale flesh-color. The spleen weighed six ounces. Both kidneys were pale; the right weighed seven ounces, the left seven ounces and a half. The mucous membrane of the fundus of the stomach was blackish, the rest mottled gray and crimson. The small intestine was healthy, but much distended with gas; Peyer's patches healthy and not ulcerated. The mucous membrane of the large intestine was slate-colored, but there were no ulcers except one or two small ones near the anus. The transverse colon was much distended with gas. The omentum small, almost denuded of fat, and pushed up toward the diaphragm.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 365.—Private Charles Peifer, company B, 52d New York volunteers; enlisted August 14, 1861; admitted February 27, 1863. Chronic diarrhœa. The patient stated that he had enjoyed good health until June, 1862, when he contracted diarrhœa on the peninsula; had been in regimental or general hospital ever since. He caught cold in January, 1863; since that time he has had more or less cough and dyspnœa. June 22, 1863, when this memorandum was taken, the patient was in a dying condition. He had dyspnœa, constant inclination to cough, and much mucous rattling in the throat. Chest resonant on percussion, but hepatic dulness as high as the fifth rib. His feet are swollen, and have been so for the last six weeks. He is exceedingly weak, and his general appearance is that of a consumptive. He has constant diarrhœa; tongue clean and red; pulse 102; abdomen painful on pressure. He died June 23d. *Autopsy* four hours after death: Height five feet six inches; upper part of body very much emaciated; abdomen swollen; legs œdematous. The lining membrane of the trachea was pale, that of the bronchial tubes purplish. The upper lobe of the right lung was adherent to the thoracic parietes, and infiltrated with tubercles; it contained a cavity the size of a chestnut near its apex; this cavity was filled with pus; in the lower lobe were a number of cheesy tubercles the size of marrow-fat peas; the pulmonary tissue between these tubercles was congested. There were firm pleuritic adhesions on the left side. In the apex of the upper lobe of the left lung were numerous disseminated tubercles; the lower lobe was congested. The right lung weighed twenty-five ounces, the left twenty-four. The pericardium contained two drachms of limpid serum. The heart weighed eight ounces; the right auricle and ventricle contained large clots, the left auricle a small one. The liver presented the nutmeg appearance; it measured thirteen inches by six, and was two inches thick; the gall-bladder contained seven drachms of blackish-green bile. The spleen weighed thirteen ounces and

a half, was moderately firm, and of a dull-lake color. The pancreas weighed three ounces and a quarter. The right kidney weighed five ounces, the left five and a quarter; both kidneys were pale, their cortical substance yellowish. The omentum was contracted and doubled up under the stomach. The mucous membrane of the stomach was slate-colored. The duodenum was healthy. Peyer's patches were ulcerated. The large intestine was thickened and extensively ulcerated.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 333.—Private David Walker, company D, 49th Pennsylvania volunteers; admitted July 30, 1863. Chronic diarrhœa. Had suffered from this disease since April 12th. When admitted he was very much emaciated, and had considerable fever; tongue flabby and furred; pulse 64; bowels loose; stools thin, and varying from four to twelve daily; appetite poor. August 7th: Is very restless; has no appetite; suffers much from thirst; tongue parched; has high fever, and some sordes on the teeth; lies in a half unconscious state. August 8th: The stools are involuntary, quite watery, and produce green stains on linen. Died, August 9th. *Autopsy* twenty-three hours after death: Body emaciated; rigor mortis well marked; apparent age 23; height five feet nine inches. The brain was moderately firm, and weighed forty-nine ounces and a half. The mucous membrane of the trachea was of a greenish color, probably due to post mortem change. The lymphatic glands at the bifurcation of the trachea were very large, soft, greenish, and contained some calcareous matter. The right lung weighed seventeen ounces and a half; the posterior portion of its upper and middle lobes and the whole of the lower lobe were engorged with venous blood; the left lung weighed fourteen ounces; its upper lobe was congested at the apex, healthy elsewhere; the lower lobe was œdematous, purplish exteriorly; on section a large quantity of thin watery fluid poured out. The heart weighed six ounces and a half; its valves were healthy; it contained no clots; the endocardium was purplish. The liver was very flabby; it weighed forty-three ounces; the gall-bladder contained four drachms of bile. The spleen was firm and of a mahogany color; it weighed six ounces. The pancreas was healthy, and weighed three ounces. The cortical substance of the kidneys was pale, the pyramids purple, the pelves bluish; the kidneys weighed five ounces and a half each. The walls of the small intestine were quite thin; its mucous membrane presented a dark-purple congested appearance; Peyer's patches, which were not swollen, were of a dingy stone color, with central dots of pigment in the follicles composing the patches. The large intestine presented nothing remarkable except in its lower portion, where the mucous membrane was of a deep crimson color; there was no ulceration or exudation of lymph on its surface.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 367.—Private Elbridge C. Crane, company D, 1st Maine cavalry; admitted August 18, 1863. Chronic diarrhœa. [This man appears on the hospital register of the Cavalry corps of the army of the Potomac, Warrenton Junction, Virginia, admitted August 15th—diarrhœa—sent to general hospital August 18th.] Died, August 23d. *Autopsy* seven hours and a half after death: Body well developed; rigor mortis strong; apparent age 20; height five feet six inches. The brain was firm, and weighed fifty-four ounces; the pia mater was injected, particularly on the external side of the left hemisphere. The lateral ventricles contained half a drachm of clear serum slightly tinged with blood. The mucous membrane of the upper portion of the œsophagus was pale, toward the cardiac orifice it was darker colored. The mucous membrane of the upper portion of the trachea was pale, lower down it was purplish between the rings. The bronchial gland at the bifurcation of the trachea contained a calcareous deposit. The right lung weighed twelve ounces and a half, the left ten ounces; both lungs were congested. The pericardium contained a drachm and a half of fluid. The heart weighed eight ounces; its valves were healthy; the right auricle was filled with a soft black clot, which extended into the right ventricle and thence into the pulmonary artery; there were no clots on the left side. The liver was of a light-purple color, its acini well marked, its capsule readily torn; it weighed sixty-seven ounces; the gall-bladder contained eight drachms of dark greenish-brown bile. The spleen was very firm, of a liver-color on section, and weighed five ounces and a half. The pancreas was pale but healthy, and weighed two ounces and a half. The right kidney weighed four ounces; weight of the left not recorded; both were slightly congested, their capsules readily torn, their pelves pale. The suprarenal capsules were lighter externally than internally, and of a brownish-ochre color. The mucous membrane of the stomach was firm and of a grayish color. The small intestine was healthy, except in its lower third, where the mucous membrane was congested. The mucous membrane of the large intestine presented a ragged appearance, due to the irregular distribution of a diphtheritic exudation; this was of a light-greenish color, and lay in a thick layer on the surface; those portions of the membrane which were not covered by the exudation presented an angry inflamed appearance and minute ecchymosed spots.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 368.—Private John A. Poer, company D, 4th Georgia (rebel) infantry; age 23; admitted August 3, 1863. Chronic diarrhœa. Died August 23d. *Autopsy* twenty-seven hours after death: Body emaciated; rigor mortis slight; height five feet seven inches. The brain was healthy, and weighed forty-eight ounces and a half. The mucous membrane of the œsophagus was of a deep-yellow color throughout, roughened above, smooth below; that of the trachea was pale, slightly purplish between the rings; the trachea contained a brownish fluid. The right lung weighed fifteen ounces and a quarter, the left twelve and a half; the lower lobes of both lungs were deeply congested. The pericardium contained half a drachm of fluid. The heart weighed eight ounces and a half; the right ventricle contained a long fibrinous clot, which extended a short distance into the pulmonary artery; the left cavities were filled with venous blood, part of which formed a soft clot in the ventricle. The liver was healthy, and weighed forty-eight ounces. The spleen was unusually firm, of a dark grayish-red color internally, grayish-green externally; it weighed five ounces. The pancreas was healthy, and weighed two ounces and a half. The right kidney weighed five ounces and a quarter, the left five and a half; in both the cortical substance was pale and slightly injected on the surface, the pyramids purple, the pelves pale; at the upper portion of the right kidney there was a depressed softened spot in which the parenchyma was undergoing some degenerative change. The small intestine was healthy. The large intestine was extensively ulcerated. The ulcers were small, mostly distinct, but occasionally confluent; they had blackish borders and pale bases. In the lower portion of the intestine the mucous membrane was dark colored, and presented a few patches of discolored shreddy exudation.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 369.—Private Orange Pickett, company K, 7th Michigan cavalry; age 33; admitted August 18, 1863. Chronic diarrhœa. [This man appears on the register of the hospital of the Cavalry corps of the army of the Potomac, then near Warrenton Junction, Virginia, admitted August 16th—diarrhœa—sent to general hospital August 18th.] Died, August 24th. *Autopsy* twenty hours and a half after death: Body not emaciated; rigor mortis strong; height five feet six inches. The brain was healthy, and weighed fifty-four ounces; the lateral ventricles contained but little fluid. The mucous membrane of the œsophagus was pale above, of a light-ochre color toward the cardiac orifice. The trachea contained a small quantity of frothy secretion; its mucous membrane was pale with purplish spots, the spaces between the rings being of a darker hue than the rings themselves. There were extensive old pleuritic adhesions on the right side. The right lung weighed nineteen ounces and a half; it was congested throughout, but sections floated in water; the left lung also was congested, and weighed eighteen ounces and a half. The pericardium contained four drachms and a half of fluid. The heart weighed ten ounces; its valves were healthy; its right cavities contained a large fibrinous clot which extended into the pulmonary artery beyond its bifurcation; the left cavities contained a smaller clot. The liver was firm, its acini well marked, its capsule readily elevated; it weighed seventy-six ounces and a half; the gall-bladder contained eight drachms and a half of thick tar-like sienna-brown bile. The spleen weighed fourteen ounces; it was of a dark flesh-color externally; its trabeculæ were prominent, its texture unusually firm. The pancreas was firm and of a dull white color. The kidneys were flabby, and weighed five ounces and a half each; their cortical substance was unusually pale, with slightly injected vessels, the pyramids of a darker hue, the pelves of a delicate pink; the left kidney was somewhat more injected than the right. The small intestine presented nothing abnormal except in its lower third; here the mucous membrane was of a dark-purple color and greatly softened, being readily detached by the finger-nail; the purple color seemed to be below the surface, and was surmounted by a tawny-green appearance resembling an exudation; this was due to the altered color of the villi, as was evident on placing the specimen under water; Peyer's patches were not affected, and the solitary glands were not visible. The large intestine, from one end to the other, presented extensive ragged confluent ulcerations; the surface was studded irregularly with elevated patches of a dark-red color, which at first sight resembled mucous membrane, but which were found to consist of a soft exudation-product readily removed by the finger.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 370.—Private Robert Johnson, company I, 11th North Carolina (rebel) infantry; admitted August 3, 1863. Chronic diarrhœa. Died, August 25th. *Autopsy* four hours and a half after death: Body greatly emaciated; rigor mortis very strong; apparent age 20; height five feet six inches. The brain was pale, of normal consistence, and weighed forty-six ounces and a half; the veins of the pia mater contained but a small quantity of blood; the lateral ventricles contained a drachm of clear serum. The right lung weighed twelve ounces, the left nine and a half; both lungs were of a grayish-slate color anteriorly, and posteriorly pink with purplish patches; a considerable quantity of dark venous blood escaped from cut surfaces on pressure; the lower lobe of the right lung presented posteriorly a hard spot about two inches in diameter, which extended into the parenchyma about half an inch, and was apparently the result of former inflammation; numerous delicate adhesions were found between the lobes of the left lung. The mucous membrane of the upper part of the œsophagus was very pale, in the lower part it was slightly injected; that of the larynx and trachea was also pale; the spaces between the tracheal rings were slightly purple. The trachea contained a small quantity of yellowish-white mucus. The pericardium contained a drachm and a half of clear light straw-colored fluid. There was some emphysema of the cellular tissue surrounding the pericardium. The heart weighed eight ounces and a half; its valves were healthy; the right cavities contained a firm fibrinous clot of a dirty reddish hue, which extended into the superior vena cava and the pulmonary artery; the left ventricle contained a mixed clot. The surface of the liver was light purple with yellowish spots; internally it was of a yellowish chocolate color; its acini were well marked; it weighed forty-seven ounces; its left lobe was very small, ($4\frac{1}{2} \times 2\frac{1}{2} \times 1$ inch;) the gall-bladder contained an ounce and a half of clear straw-yellow bile with a yellowish flocculent sediment. The spleen weighed three ounces and a half; its surface was in part purplish-blue, in part greenish-slate color, the interior was of a chocolate-red; the Malpighian bodies were numerous and well marked; the organ was rather firmer than usual. The pancreas was firm, yellowish-white, and weighed three ounces. The kidneys were pale, and weighed four ounces and a half each; the right kidney presented on its upper part two elliptical cysts about a quarter of an inch in long diameter. The rugæ of the stomach were unusually well marked. The mucous membrane of the jejunum and upper part of the ileum was pale; in the lower third of the ileum it presented a purplish appearance, and Peyer's patches were somewhat injected. The cæcum was of a deep-purple color; the whole tract of the large intestine presented numerous minute round ulcers, which were thickly crowded together; in the sigmoid flexure and the rectum were irregular patches of a tawny-green color, varying in size from an inch and a quarter to half an inch in diameter, from which the mucous membrane appeared to be entirely removed.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 371.—Corporal John A. Pitts, company B, 7th Wisconsin volunteers; age 35; admitted June 24, 1863. Chronic diarrhœa. This man was healthy when enlisted. He was first taken sick while on duty near Falmouth, Virginia, about a month and a half ago. Has now four or five watery light-colored passages daily. September 1st: About the beginning of last month the patient seemed in a fair way to recover. He is now much worse, the passages numbering eight or more daily; the abdomen is sunken and painful to the touch, the tongue dry and red. He is very much emaciated. Died, September 10th. *Autopsy* twenty hours after death: Body slightly emaciated; some rigor mortis; height five feet seven inches. The brain was firm, and weighed fifty-four ounces; the vessels of the pia mater contained rather less blood than usual; the ventricles were empty. The mucous membrane of the œsophagus was of a greenish-blue color, in its lower part it was slightly yellow; that of the trachea was pale, slightly purple between the rings; there was a small quantity of frothy mucus at the bifurcation of the bronchial tubes. The lungs were crepitant throughout, but congested posteriorly, especially in the lower lobes; on section of these a good deal of venous blood exuded, mixed with frothy serum. The heart weighed nine ounces; its right cavities contained a small fibrinous clot which extended into the pulmonary artery; the left cavities were contracted and empty. The liver was healthy, and weighed fifty-one ounces and a half; the gall-bladder contained five drachms of thick greenish bile of the consistency of molasses. The pancreas was normal, and weighed two ounces. The spleen weighed four ounces and a half; its capsule was

greenish and somewhat corrugated; it was lobed at its upper extremity; its interior of a reddish chocolate-brown color; the Malpighian corpuscles and the trabeculæ were prominent. The kidneys were healthy; the right weighed five ounces and a half, the left five ounces. The mucous membrane of the stomach was a greenish color, with minute bloody points at the pyloric extremity. The small intestine was healthy, except that the lower part of the ileum was much congested, and presented at one spot, near the ileo-cæcal valve, a greenish exudation. The large intestine was extensively ulcerated throughout its whole course; the ulcers were generally of an ovoid form, their long diameter transverse to the course of the intestine; they varied in size from that of a split-pea to that of a pin's head, many of them surrounded by a greenish exudation of lymph; and a similar exudation appeared on the mucous surface between the ulcers.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 372.—Private Joseph Matthews, company G, 9th New York cavalry; admitted September 12, 1863. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 9th New York cavalry, admitted September 1st —remittent fever. He is borne on the register of the hospital of the Cavalry corps of the army of the Potomac, admitted September 8th—dysentery—and sent to general hospital September 12th.] Died, September 14th. *Autopsy:* Height five feet eight inches; apparent age 35. The brain was healthy; it weighed forty-six ounces, and contained little or no fluid. The trachea contained a few masses of tenacious mucus; its mucous membrane was purplish. The right lung weighed nineteen ounces; its upper lobe was much congested; the middle lobe was bound to the thoracic parietes by old adhesions; the left lung weighed thirteen ounces and a half; both lobes were engorged with blood. The heart weighed eight ounces and a half; the right auricle was empty; its lining membrane was dark-red; the right ventricle contained a quantity of venous blood, and a thin fibrinous clot which extended into the pulmonary artery; the left auricle contained a small firm fibrinous clot. The liver was healthy; the gall-bladder was full of yellowish turbid bile. The spleen was firm, and weighed four ounces and a half. The pancreas was pale and firm; it weighed three ounces. The right kidney weighed five ounces; its cortical substance was of an ash-red color and rather flabby; the left kidney weighed four ounces and a half; its cortical substance was of a dark-purple color and firm. The œsophagus, stomach, and small intestine presented nothing abnormal. The mucous membrane of the cæcum and ascending colon was of a dark-green color, and presented a number of large ulcers with ragged excavated borders; in the transverse and descending colon, as far as the sigmoid flexure, the mucous membrane was thickened and covered in many places with a characteristic exudation.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 373.—Private George W. Beam, company F, 1st Pennsylvania cavalry; age 42; admitted September 12, 1863. Chronic diarrhœa. [This man appears on the register of the hospital of the 1st Pennsylvania cavalry, admitted August 11th —intermittent fever. He is borne on the register of the hospital of the Cavalry corps of the army of the Potomac, admitted August 15th—intermittent fever—returned to duty August 30th. No subsequent record can be found prior to his admission to Lincoln hospital.] Died, September 16th. *Autopsy* thirteen hours after death: Height five feet nine inches; rigor mortis slight; body not much emaciated. The vessels of the pia mater were slightly distended with blood; the ventricles contained three drachms of fluid; the brain was a little softer than usual, but otherwise healthy; it weighed fifty-three ounces and a half. The mucous membrane of the œsophagus was firm; its upper portion had a faint purplish tinge, the lower portion was light-yellow. The trachea contained a quantity of frothy secretion; its mucous membrane was pale, but had a slight purplish tinge between the rings. The lungs were of a dark bluish-slate color externally. The right lung weighed seventeen ounces and a half; its upper and middle lobes were bound together by old adhesions; it was crepitant throughout, of a dirty red mottled with green on section, and venous blood mixed with frothy mucus exuded from the cut surfaces on pressure; the lower lobe was rather more congested than the others; the left lung weighed sixteen ounces, and presented the same characteristics as the right. There was very little pericardial fluid. The heart weighed eight ounces; its right cavities contained large, firm, fibrinous clots, which extended into the pulmonary artery beyond its bifurcation; the left ventricle contained a small fibrinous clot extending into the aorta; there was a small quantity of venous blood in the left auricle. The liver weighed sixty-four ounces; it was unusually pale, its capsule readily separated, its acini indistinct; the gall-bladder contained a drachm of thick orange yellow bile. The pancreas was white and firm; it weighed three ounces and a half. The spleen was firm; its parenchyma was of a pale chocolate-color; it weighed four ounces and a half. The right kidney weighed four ounces, the left four and a half; the cortical substance of both was pale, the pyramids injected, the pelves pale. The small intestine was healthy down to the lower part of the ileum, the mucous membrane of which was of a deep-purplish color, thickened and coated with shreds of coagulated lymph, which was in some places yellowish, in others of a dark-green hue. The cæcum presented a few ovoid ulcers with marked vascular congestion around them. The lower part of the large intestine was extensively ulcerated, the mucous membrane in some places being almost entirely destroyed; the ulcers were small, ovoid, and the mucous membrane between them was coated with a thick layer of lymph, which was greenish in some places, reddish in others.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 374.—Private Mark Colgin, company M, 13th Pennsylvania cavalry; admitted September 17, 1863. Chronic diarrhœa. Died, September 18th. *Autopsy* four hours after death: Body not much emaciated; rigor mortis well marked; apparent age 20; height five feet five inches. The veins of the pia mater were moderately filled with dark blood; the ventricles contained half a drachm of grayish fluid; the brain was firm and apparently healthy; it weighed forty-seven ounces. In the upper part of the œsophagus there were a number of slightly elevated white maculæ, between which the mucous membrane was of a light-purple color; in the lower part of the œsophagus the membrane was reddish. The trachea was full of thick frothy mucus; the membrane over the rings was pale, between them it was unusually purple. The exterior of the lungs was of a grayish-purple with bluish spots, which were most numerous posteriorly; on incision both lungs were found to be congested posteriorly, and a quantity of frothy mucus exuded; the lobes of the right lung were bound together by old fibrinous bands. The pericardium contained nine drachms of straw-colored fluid. The heart weighed thirteen ounces; its right cavities contained venous clots; the lining membrane of the right auricle was reddened; the left auricle was empty, its lining membrane pale; the left ventricle contained a small venous clot. There was a small quantity of straw-colored serum in the abdominal cavity. The omentum was loaded with fat. The liver was healthy; it weighed fifty-nine ounces; the gall-bladder contained six drachms of orange-yellow

bile. The pancreas was normal, and weighed two ounces and a half. The spleen was soft, of a dark-purplish color internally, the Malpighian corpuscles well-marked; it weighed thirteen ounces and a half. The kidneys weighed five ounces each; both were slightly congested, the right most so. The mucous membrane of the stomach was pale, with a few reddish points; that of the small intestine was unusually pale. In the lower part of the ileum Peyer's patches were slightly elevated, and one of them near the cæcum ulcerated; the solitary glands were enlarged, reddened, and slightly ulcerated. The mucous membrane of the large intestine was also generally pale; in its upper portion it presented numerous bright-red spots with ulcers in their centres; these were apparently the solitary glands, which here, as in the small intestine, seemed to be the chief seat of the disease. The mesenteric glands were enlarged.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 375.—Private Edward McCann, company G, 69th Pennsylvania volunteers; age 34; admitted September 12, 1863. Chronic diarrhœa and hepatic abscess. Died, September 27th. *Autopsy* fourteen hours after death: Height five feet ten inches; some rigor mortis. The brain weighed fifty-two ounces; it was somewhat soft. The mucous membrane of the trachea was generally pale, the spaces between the rings slightly purplish. The right lung weighed nine ounces and a half; it was pale and anæmic except the lower lobe, which was somewhat congested posteriorly; the left lung weighed eight ounces, and presented the same appearances as the right; both lungs were peculiar from the absence of the frothy bronchial secretion usually seen on section. The pericardium contained six drachms of fluid. The heart weighed eight ounces; in the right auricle there was a large fibrinous clot which extended upward into the descending vena cava, downward into the ventricle, and thence into the pulmonary artery; the left side of the heart also contained a fibrinous clot, but of smaller dimensions than that in the right. The liver measured eleven by eight by five inches; it contained a number of purulent deposits; these appeared on the external surface as whitish circular spots, about an inch and a half in diameter, surrounded by a purple areola; some of them had a little fibrinous lymph adhering over them; between them the surface of the liver was mottled with yellow and red; on section the parenchyma was pale except immediately around the deposits, where it was congested. The spleen was firm and dark colored; it weighed five ounces and a half. The right kidney was healthy, and weighed four ounces and a quarter; the left kidney was markedly congested, and weighed four ounces and a half. The small intestine appeared to be perfectly healthy. The large intestine, from the cæcum down, was extensively ulcerated; the mucous membrane between the ulcers was of a dark stone-gray color, and not covered by any exudation; the ulcerated patches, however, had a thin diphtheritic coating on the exposed muscular coat.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 376.—Private Hezekiah S. Palmer, company E, 42d Mississippi (rebel) volunteers; admitted August 18, 1863. Chronic diarrhœa. Died, October 10th. *Autopsy:* Rigor mortis not marked; body not much emaciated. The brain was healthy; it weighed fifty-two ounces. The right pleural sac contained three ounces and a half of fluid, the left four ounces. The trachea was filled with a thin bronchial fluid; its mucous membrane was pale. The right lung weighed nineteen ounces and a half; its upper and middle lobes appeared pale on section, and exuded a quantity of thin bronchial secretion; the lower lobe was congested, and the bronchial secretion was mixed with blood; this lobe was bound to the thoracic parietes by old fibrinous adhesions; the left lung weighed twenty-three ounces and a half; its upper lobe resembled that of the right lung; the lower lobe was purplish-red externally, with a quantity of shreddy recent lymph adhering to its surface; the upper two-thirds of this lobe were in a state of red hepatization. The heart weighed ten ounces and a quarter; its valves were healthy; the right auricle contained a venous clot, the right ventricle a large, soft, fibrinous one; there was a thin ribbon-like clot in the left auricle. The liver weighed forty-seven ounces; it was pale, firm, its capsule easily torn, its acini prominent; the gall-bladder contained eight drachms of brownish flocculent bile. The spleen was readily broken up; it weighed ten ounces and a half. The pancreas weighed three ounces and a quarter. The right kidney weighed five ounces and a half, the left five. The intestines were anæmic and of a stone-gray color externally; the mucous membrane was flaccid and pale; the valvulæ conniventes were nowhere prominent, and in some places were absent; the mucous membrane was extremely soft and readily removed. This case is interesting inasmuch as chronic diarrhœa had existed for a long time and no ulceration of the large or small intestine was observed after death.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 377.—Drummer David Ebert, company I, 126th New York volunteers; admitted from the army of the Potomac September 12, 1863. Chronic diarrhœa. Died, October 22d, of diphtheria and pneumonia. *Autopsy* thirty-six hours after death: Apparent age 22; height five feet eleven inches; some rigor mortis; body not much emaciated. The brain weighed fifty-seven ounces and a half; it was moderately firm; there was but little fluid in the ventricles; the pia mater was moderately injected. The œsophagus was pale except at its upper portion, where it was of a mottled purple color, and covered by a diphtheritic exudation continuous with that lining the pharynx and larynx; the mucous membrane of the larynx and trachea was of a dark-purple color, and coated with a thick consistent layer of diphtheritic membrane which extended into the bronchial tubes; this pseudomembrane was also of a purple color, being darkest on the side next the mucous membrane. The right lung weighed thirty-three ounces and a half; the greater portion of its upper lobe and the posterior part of the middle lobe were in the stage of red hepatization; there were also a number of hepatized lobules in the lower lobe, the dark color of which contrasted strikingly with the brighter red of the intervening congested but still permeable parenchyma; the left pleural cavity contained twenty-four ounces of straw-colored serum. The left lung weighed twenty ounces and a half; its upper lobe was emphysematous anteriorly, posteriorly it was infiltrated with yellow serum, and portions sank in water; the lower lobe was in a similar condition in its upper portion, its lower portion was hepatized red; in the apex of this lung there were a few tubercles, some of which had become cretefied. The pericardium contained an ounce of fluid. The heart was healthy, and weighed nine ounces and a quarter; the left ventricle contained a whitish fibrinous clot mottled with red in the centre and ragged on its edges. The liver weighed fifty-seven ounces and a half; it was engorged with purple blood, its parenchyma extremely soft, its acini prominent on account of the venous engorgement of the portal veins; the gall-bladder contained ten drachms of dark-green moderately viscid bile. The pancreas was flesh-colored, and weighed two ounces and three-quarters. The spleen was pultaceous and of the color of elderberry juice; it weighed four ounces and three-quarters. The kidneys were much congested; the right weighed five ounces.

the left five and a half. The small intestine was healthy except in the lower third of the ileum, where Peyer's patches and the solitary glands were slightly elevated and whitened. The large intestine was contracted, the mucous membrane being in consequence thrown into tortuous folds; it was congested near the cæcum, and of a stone-gray color elsewhere.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 378.—Private Kinkin Clark, company C, 44th North Carolina volunteers; admitted October 20, 1863. Chronic diarrhœa. Died, October 24th. *Autopsy* twenty-two hours after death: Apparent age 45; height five feet nine inches; rigor mortis slight; body not much emaciated. The brain was firm, and weighed fifty-one ounces and a half; there was but little fluid in the ventricles. The mucous membrane of the trachea was irregularly purplish in spots, between which it was pale. The lungs were engorged with venous blood, but crepitant throughout; the right lung weighed fifteen ounces and a half, the left fourteen ounces. The pericardium contained nine drachms of fluid. The heart was normal, and contained no clots except a very small one in the right ventricle. The liver weighed seventy ounces and a half; its substance was normal in color and consistence, except at the left extremity of the left lobe, where it was firmer than elsewhere, coated by old exudations, and attached to the spleen; the gall-bladder contained six drachms of bile resembling coffee-grounds. The spleen was firm, and weighed twenty-three ounces; it was of a pale grayish-blue externally, and of a dark-mulberry color internally; it was firmly agglutinated to the liver; the adhesion was extremely thick, and cut like cartilage. The pancreas was of normal consistence, and weighed four ounces. The kidneys were large; the right measured five inches by two and a half, and weighed seven ounces and a half; the left measured five inches by three, and weighed eight ounces; the cortical substance of both was pale but injected, the section appearing as if sprinkled with red pepper; the bases of the pyramids were of a very dark-purple color, the capsules readily elevated, the pelves highly injected. The mucous membrane of the small intestine was softened and of a stone-blue color, which increased in intensity toward the ileo-cæcal valve; the agminated glands were not elevated or thickened, but presented a few ulcers which varied from the size of a mustard-seed to that of a split-pea; the solitary glands were prominent, but not ulcerated. The ileo-cæcal valve was the seat of an irregular shallow ulceration. The cæcum was intensely congested, its solitary glands conspicuous and whitish; the mucous membrane of the rest of the large intestine was softened and of a pale yellowish-slate color.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 379.—Sergeant Benjamin Russell, company I, 13th Massachusetts volunteers; admitted October 24, 1863. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 13th Massachusetts volunteers, admitted September 24th—acute diarrhœa—sent to division hospital October 15th. He is borne on the register of the hospital of the 2d Division, 1st Corps, admitted October 19th—chronic diarrhœa—sent to general hospital October 24th.] Died, October 25th. *Autopsy* twenty hours after death: No rigor mortis; body much emaciated; apparent age 34; height five feet eight inches. The brain was healthy, and weighed forty-seven ounces. The mucous membrane of the trachea was readily torn; it was generally pale, but somewhat purplish between the rings. The right lung weighed twenty-nine ounces and a quarter; its upper lobe was hepatized posteriorly and presented at its apex a tubercular deposit about the size of a chestnut, in which there was a cavity partly filled with softened tubercular matter; the middle lobe was in the stage of gray hepatization; it was coated externally with a thick layer of lymph; the lower lobe was in the stage of splenization; a large amount of greenish frothy fluid exuded on pressure; the lobe was covered posteriorly with old adhesions. The left lung weighed twenty-two ounces and a half; its upper lobe contained a number of small vomicæ, the lower lobe was in the stage of gray hepatization. The pericardium contained seven drachms of fluid. The heart weighed six ounces and a half; its valves were healthy; the endocardium was of a dark-purple color; both cavities contained soft whitish clots and a considerable quantity of venous blood; the clot in the left side was larger than that in the right. The liver was healthy; it weighed forty-two ounces and a half; the gall-bladder contained an ounce and a half of dark-brown very viscid bile. The spleen weighed four ounces and a half; it was of a dark-mulberry color and rather friable. The pancreas was healthy, it weighed an ounce and three-quarters. Both kidneys were congested; the right weighed four ounces, the left four and a half. The small intestine was healthy, except that its walls were thin; Peyer's patches were not elevated. The large intestine from the rectum upward was extensively diseased; numerous small punctated ulcers were observed along the tract; the mucous membrane was thickened and irregularly covered by a fine granular exudation which was most abundant near the rectum; the cæcum was of a dull-slate color, the colon congested.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 380.—Private Samuel Ryckman, company C, 6th Michigan cavalry; admitted July 30, 1863. Chronic diarrhœa. Died, October 27th. *Autopsy* sixteen hours after death: Height five feet ten inches; no rigor mortis; emaciation extreme. The brain was somewhat soft; it weighed forty-seven ounces and a half. The mucous membrane of the trachea was pale. The right lung weighed fifteen ounces and three-quarters; its upper lobes were healthy, the lower lobe somewhat congested, and a tenacious mucus exuded from the bronchial tubes on pressure. The left lung weighed fourteen ounces and a half; in its apex was a mass of tubercle the size of a walnut, which was just beginning to soften; the lower lobe was in a state of venous congestion, the mucous membrane of its bronchial tubes inflamed; the bronchial glands were large, soft and black. The pericardium contained two drachms of fluid. The heart was healthy; it weighed seven ounces and a quarter. The liver was of firm consistence, pale-yellow color, and fatty; it weighed fifty-seven ounces and three-quarters; the gall-bladder contained ten drachms of bile. The spleen was firm, of a dark-mulberry color on section, and weighed ten ounces and a half. The pancreas weighed two ounces and three-quarters. The kidneys were slightly congested; the right weighed five ounces and a quarter, the left three and three-quarters. The upper portion of the small intestine was healthy; in the lower part of the ileum the mucous membrane was thin, soft, and congested; the valvulæ conniventes were almost obliterated; Peyer's patches were of a dull-slate color, but not prominent or ulcerated. The large intestine was extensively ulcerated from the cæcum to the anus; some of the ulcers were very deep, their outlines exceedingly irregular, their bases of a dark blue-stone color; no solitary glands were visible, and no diphtheritic membrane was present. In the transverse colon the ulceration was very superficial.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 381.—Corporal Charles P. Stevens, company B, 126th New York volunteers; age 33; admitted September 12, 1863. Chronic diarrhœa. Died, November 5th. *Autopsy* twenty-four hours after death: Height five feet nine inches; rigor mortis well marked; emaciation extreme; abdomen covered with numerous spots. The brain weighed forty-nine ounces; there was a drachm of fluid in the ventricles. The mucous membrane of the trachea was extremely pale. The right lung weighed twenty-four ounces; there were a few tubercles in the lower part of its upper lobe; the middle lobe was free from them, and they were numerous in the lower lobe, in which they were associated with intercurrent pneumonia, which in some parts had advanced to gray hepatization; the lower lobe of the left lung was in much the same condition; its upper lobe was free from tubercles; bronchitis was present on both sides, especially in the lower lobes. The pericardium contained six drachms of straw-colored serum. The heart and its valves were healthy; there was a small fibrinous clot in the right side, none in the left. The liver presented the nutmeg appearance, and weighed fifty ounces; the gall-bladder contained six drachms of dark reddish-brown bile. The spleen was quite firm, and weighed four ounces. The pancreas weighed two ounces. The kidneys were firm and rather pale; the right weighed four ounces, the left five. The walls of the small intestine were very thin; the mucous membrane was soft, the vessels congested. The mucous membrane of the large intestine was ulcerated; most of the ulcers were irregular in form, and blackish, with rather low abrupt walls; toward the cæcum they were small and punctated; wherever the mucous membrane remained intact, it was whitish and lardaceous in appearance, except near the rectum, where it was uniformly pink.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 382.—Private Thomas Shannon, company F, 42d New York volunteers; age 25; admitted September 12, 1863. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 24th New York volunteers, admitted August 24th—diarrhœa—sent to general hospital September 10th.] The patient stated that he had been sick four months; was extremely emaciated; his hair was dry and long; his eyes were dim, but ulceration of the cornea had not yet taken place; the skin was of a dull yellowish-slate color, and slightly furfuraceous; the abdomen was much depressed; the feet and toes were persistently cold, the toes bluish. About the 13th of October he began to sink rapidly, but with singular vitality he reacted from a condition bordering upon death, and for several weeks improved so greatly that hopes of his recovery were entertained. He subsequently became languid and exhausted, the diarrhœa became again more violent, and he died November 19th, at 7.30 A. M. *Autopsy* six hours after death: Height five feet nine inches; rigor mortis well marked; body much emaciated. The brain was healthy, and weighed fifty-seven ounces; the ventricles contained a drachm of serum; the quantity of subarachnoid fluid was larger than usual. The mucous membrane of the trachea was pale. The right lung was collapsed, and weighed eight ounces and a half; it contained an abundance of pigment and some softened tubercles at its apex; the left lung was also collapsed, and weighed nine ounces. The pericardium contained six drachms of serum. The heart was healthy, and weighed eight ounces; its right cavities contained a soft black clot, and a similar one was found in the left ventricle. The liver was of a pale-yellowish color, apparently fatty; it weighed fifty-five ounces and a half; the gall-bladder contained eight drachms of dark tar-like bile. The spleen was firm, of a reddish mahogany-color, and weighed eight ounces and a half. The kidneys were pale and anæmic; the right kidney weighed three ounces and a half, the left four and a half. The pancreas was hard and tallow-like; it weighed two ounces. Seven feet above the ileo-cæcal valve the mucous membrane of the small intestine assumed a granular appearance, which became more marked farther down, assuming more and more the characters of an exudation of lymph. The exudation was arranged on the surface of the valvulæ conniventes, or in lines parallel to them, for they were quite indistinct, and in some places entirely obliterated; toward the ileo-cæcal valve the deposit was yellowish, pultaceous, and resembled the false membrane in diphtheria; just above the ileo-cæcal valve, midway between the mesenteric attachment and Peyer's patches, there was an ulcer which had perforated the ileum and communicated with a perforating ulcer in the cæcum; between the two ulcers was a small cavity containing pus, which was bounded by the intestinal walls, the iliac muscle, and a portion of the great omentum, which had become adherent, and appeared to have prevented the extravasation of the intestinal contents into the abdominal cavity. The colon was ulcerated throughout.—Assistant Surgeon Harrison Allen, U. S. A. [Nos. 116 to 118, Medical Section, Army Medical Museum, are from this case. Nos. 116 and 117 are successive portions of the thickened ileum; the mucous membrane is coated with pseudomembrane, and presents a number of ulcers. In No. 117 the opening of the abscess above described into the ileum is seen. The corresponding portion of the cæcum was, unfortunately, not preserved. No. 118 is a portion of the colon of the same patient, which is greatly thickened, and coated with pseudomembrane.]

CASE 383.—Private William O. Pollard, company C, 44th North Carolina (rebel) volunteers; admitted October 25, 1863. Chronic diarrhœa. Died, November 19th. *Autopsy* next day: Height five feet ten inches; no rigor mortis. The brain was healthy, and weighed fifty-seven ounces. There were no pleuritic adhesions. The right lung weighed seventeen ounces, the left fifteen; the lower lobes of both were congested hypostatically. The pericardium contained four ounces of fluid. The heart weighed nine ounces; its right cavities contained a large flesh-colored clot, the left cavities a similar but smaller clot; the valves were healthy. The liver weighed fifty-seven ounces; its parenchyma was pale and not very firm, its capsule readily torn; the gall-bladder contained ten drachms of dark-green very viscid bile. The spleen weighed seventeen ounces; it was tolerably firm, and of a dark mahogany-color. The pancreas weighed three ounces. The kidneys were pale and flabby; the right weighed six ounces, the left seven. The large intestine was very much ulcerated, and presented the appearance commonly found in long-existing diarrhœa.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 384.—Private John Finch, company A, 47th North Carolina (rebel) volunteers; admitted October 25, 1863. Chronic diarrhœa. Died, November 26th. *Autopsy:* Apparent age 48; height five feet seven inches; some rigor mortis; body very much emaciated. The brain was apparently healthy, and weighed fifty-two ounces and a half; the ventricles contained two drachms of turbid serum tinged with blood. The trachea was slightly purplish toward its bifurcation, but pale elsewhere. The right lung weighed sixteen ounces; the posterior portion of its upper and the whole of its lower lobe were in the stage of red hepatization; the left lung weighed fifteen ounces; it was crepitant throughout; its bronchial tubes contained a pus-like secretion.

The pericardium contained a drachm of fluid. The heart was healthy; there was a small white clot in the right side, none in the left. The liver was dark-brown in color, of normal consistence, and weighed forty ounces; the gall-bladder contained ten drachms of molasses-colored viscid bile. The spleen was firm, of a dark mahogany color, and weighed four ounces and a half. The pancreas weighed two ounces. The kidneys were healthy; the right weighed three ounces, the left three and a half. The large intestine was extensively ulcerated, presenting the appearance of one large roughened ulcer.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 385.—Private Joseph Gerrold, company E, 10th Vermont volunteers; admitted November 23, 1863. Chronic diarrhœa. Died, November 29th. *Autopsy:* Height five feet eight inches; rigor mortis slight; body emaciated. The brain was healthy, and weighed forty-seven ounces; the ventricles contained two drachms of fluid. The epiglottis had a yellowish-pink color. The mucous membrane of the larynx was of a bluish cast; that of the trachea was purplish over the interspaces, whitish over the rings. The right lung weighed twenty-one ounces; the posterior portion of its upper and lower lobes was congested, the rest of the lung healthy; the left lung weighed twenty-four ounces; it was intensely congested, and the central portion of the base of its upper lobe was in the stage of red hepatization. The pericardium contained a drachm of bloody fluid. The heart and its valves were healthy; there was a large whitish clot in its right side extending into the pulmonary artery; in the left side there was a smaller clot of the same character. The liver was congested; the gall-bladder contained four drachms of slightly viscid brown-red bile. The spleen was seven inches long, by five and a quarter wide and three and a half thick; it had a dark purplish mahogany-color, and was very firm. The kidneys were pale, the left being paler than the right; the right kidney weighed six ounces, the left five and a half. The pancreas weighed two ounces. The small intestine was extremely congested; large intestine the same; the mucous membrane of the large intestine was of a dark-greenish color. The diagnosis recorded in this case was chronic diarrhœa, but none of the characteristic lesions of that disease were found. There was no ulceration, no intumescence of the solitary glands, &c. The patient died most probably of pneumonia.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 386.—Private Ephraim York, company C, 19th Maine volunteers; admitted November 23, 1863. Acute diarrhœa. Died, December 4th. *Autopsy* next day: Rigor mortis marked; body considerably emaciated; surface slightly jaundiced. The brain was healthy; it weighed fifty-three ounces; the lateral ventricles contained a drachm of fluid. The pharynx was in a state of chronic inflammation; the walls were much thickened, the constrictor muscles very pale, the mucous membrane of a dim yellowish-gray color; beneath it were numerous small abscesses about the size of peas. The epiglottis was thickened and slightly injected on its free anterior border. The mucous membrane of the larynx had the same color as that of the pharynx, except over the cricoid cartilage, where it was of a stone-blue color. The left side of the rima glottidis was tumid and coated by a whitish-yellow exudation, beneath which was an ulcer with ragged irregular edges; the base of the epiglottis on the same side also presented several ulcers, which had everted edges and were filled with a tenacious pus-like exudation; on the right side of the base of the epiglottis there was a small ulcer about the size of a buckshot; the superior borders of the chordæ vocales were also ulcerated, more extensively on the right than on the left side; these ulcers were comparatively superficial, and were coated by a whitish deposit of lymph. The mucous membrane of the trachea was yellowish-gray down to its bifurcation, where it was of an intense red. The right lung weighed twenty-seven ounces; it was very much congested, and filled with a sanguineous fluid, which poured forth on section, but crepitated on pressure everywhere; the left lung was in the same condition as the right, and weighed twenty-eight ounces. The pericardium contained an ounce and a quarter of yellow serum. The heart weighed eleven ounces; its right side contained a large, firm, fibrinous clot, with but little venous admixture; a smaller clot was found on the opposite side. The liver was firm, rather pale, and weighed forty-five ounces; the gall-bladder contained four drachms of bile. The pancreas was purplish and unusually thick. The spleen weighed twelve ounces. The right kidney weighed six ounces, the left seven ounces; both kidneys were of a dark-purple color, the pyramids being a shade or two darker than the cortical portion. The intestines were healthy, except that the lower part of the large intestine was congested.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 387.—Private Andrew Eckstine, company K, 52d New York volunteers; admitted November 23, 1863. Chronic diarrhœa. Died, December 6th. The immediate cause of death was supposed to have been imprudence in eating oysters. *Autopsy:* Height five feet one inch; rigor mortis not very well marked; body much emaciated. The brain was firm; its ventricles contained a drachm of fluid. The œsophagus was slightly purplish in its superior portion, of a greenish-ochre at the cardiac extremity. The larynx and trachea were pale. The right lung was congested, especially its lower lobe; it contained an excess of frothy bronchial secretion; the upper lobe of the left lung was in the same condition; the lower lobe was in the stage of gray hepatization. The pericardium contained two ounces of fluid. The heart was healthy; its right cavities were filled by a large venous clot, which extended into the pulmonary artery. The liver was firm, its acini well marked; there were many dark-brown spots on the surface of the organ and disseminated through its substance; the gall-bladder contained three drachms of dark-green very viscid bile. The spleen had a dark sienna-brown color and was quite firm; it measured four inches and a half by three. The pancreas was whitish and moderately firm. The cortical substance of the kidneys was pale, the pyramids injected. The small intestine was pale, anæmic, and had an ironed-out appearance; its solitary glands were conspicuous. The large intestine presented a great number of punctated ulcers, some of which were becoming confluent; the mucous membrane was of a lively red.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 388.—Private Joseph Harbaugh, company D, 6th Maryland volunteers; admitted November 23, 1863. Chronic diarrhœa and semi-gangrenous feet. [This man appears on the register of the regimental hospital of the 6th Maryland volunteers, then at Brandy Station, Virginia, admitted November 14th—typhoid fever—sent to general hospital November 23d.] Died, December 8th, at 6 P. M. *Autopsy* twenty-one hours after death: Height five feet eight inches; rigor mortis marked; body emaciated. The brain was healthy, and weighed fifty ounces; the ventricles contained a drachm of fluid. The mucous membrane of the trachea was injected. The right lung weighed twenty-four ounces; the anterior part of its upper and the whole

of the middle lobe were somewhat emphysematous; the posterior portion of the upper lobe was filled with an excessive amount of bronchial secretion, and inferiorly was in the stage of red hepatization; the lower lobe was engorged and of a dark-purple color, but crepitated under pressure; the left lung was healthy, but congested hypostatically; it weighed thirteen ounces. The pericardium contained ten ounces of fluid. The heart weighed ten ounces; its valves were healthy; the right cavities contained a large mixed clot. The liver was healthy, and weighed sixty-four ounces; the gall-bladder contained two and a half ounces of bile. The spleen was moderately firm, of a dark-purple color; it weighed eight ounces. The pancreas weighed three ounces. The kidneys were anæmic, their cortical substance unusually pale; the pyramids were also pale, but darker than the cortical substance; the right kidney weighed five ounces, the left six ounces. The large intestine presented the usual appearances of chronic diarrhœa; the ulcers were superficial, not confluent, and tinged with a delicate pink color; this condition extended some distance into the small intestine, the mucous membrane of which was congested, while the solitary glands were conspicuous and of a dark-purplish color; Peyer's patches were of a still darker color, but not elevated or ulcerated. [The condition of the feet is not recorded.]—Assistant Surgeon Harrison Allen, U. S. A.

CASE 389.—Sergeant James H. Morse, company D, 8th Pennsylvania cavalry; admitted September 17, 1863. Quotidian intermittent fever and chronic diarrhœa. Died, December 15th. *Autopsy* seventeen hours after death: Height five feet five inches; no rigor mortis. The posterior parts of the meninges were considerably congested; the brain was firm, and weighed forty-eight ounces and a half; the ventricles contained a drachm of serum. The œsophagus was pale throughout; the larynx and trachea were also pale; at the bifurcation of the trachea there was a quantity of bronchial secretion. The right lung weighed twenty-three ounces; the anterior and superior portions of its upper lobe were healthy, the posterior and inferior portions hepatized; the lower lobe was partly carnified, partly splenified; the left lung was healthy, and weighed sixteen ounces. The pericardium contained five drachms and a half of fluid resembling the white of an egg. The heart weighed eleven ounces and a half; a very small whitish-yellow clot, the size of a horse-chestnut, was found in the right side, one of similar dimensions and appearance in the left side; the valves were healthy. The liver had the nutmeg appearance, was quite fatty, and weighed sixty-three ounces; the gall-bladder contained two ounces and a half of dark-green bile, in which there was considerable sediment of an intense green color. The spleen was somewhat softer than usual, of a dark-purple color, and weighed twelve ounces and a half. The pancreas was firm, white, and weighed three ounces. The kidneys were pale and apparently fatty; the right weighed six ounces, the left six and a half. The intestines were bound together and to the abdominal parietes by fibrinous bands; the mucous membrane of the small intestine was healthy to within two feet of the cæcum; Peyer's patches and the solitary glands were not prominent; the large intestine was ulcerated throughout, most of the ulcers being punctated; they were most marked along the longitudinal bands.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 390.—Private Peleg Mitchell, company D, 16th Maine volunteers; age 61; admitted October 19, 1863. Diarrhœa and erysipelas. This man was taken sick with diarrhœa near Fairfax Court-House, Virginia, October 16th. His bowels were moved from ten to fifteen times daily; his stomach was irritable. October 23d: The patient vomits continually; tongue coated with thick white fur; pulse 108 and scarcely perceptible; extremities cold. November 3d: Is much better; the vomiting has ceased and the diarrhœa is nearly checked. November 13th: The bowels have been quite regular for a day or so, but are loose again. He had rheumatic pains when admitted, which have now disappeared. December 14th: Facial erysipelas has set in and the diarrhœa has returned; the discharges are frequent; the abdomen is tender; pulse 110 and feeble. December 16th: The erysipelatous symptoms are better, but the patient is much prostrated; the diarrhœa continues. December 18th: The erysipelas has nearly subsided; the prostration continues; there is no pain, and the evacuations are involuntary but not very frequent. Died, December 19th. This patient had from six to eight ounces of milk-punch per day. *Autopsy* next day: Body not emaciated; adipose tissue quite abundant. Brain not examined. The lower lobes of both lungs were congested; the lungs otherwise were healthy. The heart was paler than natural. The liver had the nutmeg appearance to a slight degree. The pancreas was white and firm. The spleen was firm, very dark, and filled with black blood. The kidneys were congested. The mucous membrane of the ileum was perfectly healthy, and there was no enlargement of the closed glands. [The condition of the large intestine is not recorded.]—Assistant Surgeon Harrison Allen, U. S. A.

CASE 391.—Private Samuel Hill, company F, 41st North Carolina (rebel) volunteers; admitted December 5, 1863. Chronic diarrhœa. [This man appears on the hospital register of the Old Capitol prison, taken sick October 28th with typhoid fever.] Died, December 21, 1863. *Autopsy* twenty-seven hours after death: There was some rigor mortis. The posterior part of the upper lobe of the right lung and the upper portion of the middle lobe were semi-splenified and friable, but did not sink in water; the rest of both lungs was normal. The pericardium contained five drachms of fluid. The heart was normal. The liver and kidneys were congested. The pancreas was whitish and moderately firm. The spleen small and firm. The ileum was very much congested, and presented some punctated ulcers. The large intestine was extensively ulcerated. The mesenteric glands were not enlarged.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 392.—Private William Jenkins, company C, 44th North Carolina (rebel) volunteers; admitted from Old Capitol prison October 20, 1863. Chronic diarrhœa. Died, December 31st. *Autopsy* twelve hours after death: Apparent age 21. The pharynx and larynx were healthy. The lungs were congested posteriorly; the middle lobe of the right lung was in a state of gray hepatization. The pericardium contained two ounces and a half of fluid. The heart was healthy. The liver was healthy. The spleen measured seven inches and a half by four; it was very firm. The pancreas was healthy. The kidneys were rather small and pale. The small intestine was healthy. The cæcum was somewhat congested. The ascending and transverse colon were not diseased; the descending colon and rectum were ulcerated and coated with a diphtheritic exudation.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 393.—Private Abraham Keller, company A, 6th Maryland volunteers; admitted November 23, 1863. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 6th Maryland volunteers, admitted October

22d—diarrhœa—sent to general hospital November 2d] Died, December 31st. *Autopsy:* A number of lobules in the left lung were hepatized gray; the right lung was healthy. The deep-seated cervical lymphatic glands were tubercular, (no tubercle elsewhere.) The liver was hard and presented a number of whitish lardaceous spots. The spleen was small and firm. The ileum was healthy; the colon ulcerated. Assistant Surgeon Harrison Allen, U. S. A.

CASE 394.—Private F. Lehman, 39th company, 2d battalion Invalid Corps; admitted November 11, 1863. Chronic diarrhœa. Died, January 10, 1864. This man had been wounded in action before being transferred to the Veteran Reserve Corps. The ball entered his left shoulder, between the acromion and the head of the humerus. It was found, after death, embedded immediately beneath the skin an inch below the spine of the scapula. *Autopsy:* The liver was soft and friable. The spleen measured four inches and a quarter by three; it was soft and of a pale-red color. The intestines presented the usual lesions of chronic diarrhœa. The cæcum was greatly thickened and inflamed. The peritoneal surface of the colon was inflamed and coated with thick adhesive lymph.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 395.—Private Nathan Craft, company K, 53d North Carolina regiment, (Confederate;) admitted from Old Capitol prison January 6, 1864. Chronic diarrhœa. Died, January 11th. This patient had been sick a long time with the usual symptoms of chronic diarrhœa; toward the close he had pneumonia. *Autopsy* nine hours after death: The right lung was pneumonified, the left congested and filled with sero-sanguineous fluid. The colon presented the usual lesions of chronic diarrhœa, and the rectum was coated with an exudation of lymph. The abdominal cavity contained a quantity of serum, and a thin layer of lymph united the coils of intestine; the lymph was most abundant upon the colon. The sigmoid flexure was quite firmly adherent posteriorly to the peritoneum. The spleen was very soft, and measured four inches and a half by three.—Assistant Surgeon Harrison Allen, U. S. A.

CASE 396.—Private Peter Ball, company H, 66th New York volunteers; admitted December 29, 1863. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 66th New York volunteers, admitted December 8th—intermittent fever—sent to general hospital December 11th. No subsequent account of him is found prior to his admission to Lincoln hospital.] Died, January 24, 1864. *Autopsy* forty-eight hours after death: Height five feet eight inches; the body was much emaciated. The brain weighed fifty-three ounces; the subarachnoidal fluid was abundant; the pia mater was ecchymosed in spots; the lateral sinuses were full of blood. The right lung weighed thirty-two ounces; it was congested and marked, especially on its upper lobe, by streaks of black pigment corresponding to the ribs; the left lung weighed twenty-two ounces and a half; it also was congested and marked with pigment in the same manner as the right lung; the lower lobe appeared to be consolidated, but did not sink in water. The bronchial glands were black; some of them were hardened and contained calcareous deposits. The heart weighed six ounces and a quarter; its substance was flabby, the surrounding adipose tissue abundant; there was a large fibrinous clot in the left auricle; the aorta was reddened internally. The liver weighed forty-nine ounces and a half; its substance was finely mottled; the gall-bladder contained a little light-colored bile. The spleen weighed three ounces and a quarter. The pancreas weighed two ounces. The right kidney weighed six ounces, the left kidney six and a quarter. The mucous membrane of the upper part of the jejunum was congested and softened; the valvulæ conniventes were not prominent, and disappeared in the lower part of the jejunum, so that the ileum was quite smooth. The cæcum and ascending colon were ulcerated; the ulcers were more numerous in the transverse colon, where they penetrated to the peritoneum; they were generally grouped in rows corresponding to the longitudinal muscular bands; the ulcers in the sigmoid flexure were irregular and covered with shreddy lymph. The rectum was irregularly congested.

CASE 397.—Private William Smale, company E, 67th Pennsylvania volunteers; age 22; admitted February 3, 1864. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 67th Pennsylvania volunteers, then near Brandy Station, Virginia, admitted December 14, 1863—typhoid fever—sent to general hospital February 3, 1864.] Died, February 27, 1864. *Autopsy* fifteen hours and a half after death: Height five feet ten inches and a half; body very much emaciated. The brain was soft, but apparently healthy; it weighed forty-four ounces and a half. The larynx and trachea were healthy; there were firm pleuritic adhesions on both sides, and both pleura pulmonalis and costalis were coated with a thick layer of fibrinous exudation; the right pleural cavity contained ten ounces of serum, the left eight ounces. The left lung weighed twenty-four ounces; there was a small deposit of tubercles in the base of its upper lobe; the whole lung was considerably congested, and the anterior part of its lower lobe was carnified; it sank in water; the right lung weighed nineteen ounces and a half; it was moderately congested, but otherwise healthy. The heart was healthy; weight eight ounces and a half. The pericardium contained half an ounce of fluid. The liver was bronzed; there were a few patches of fibrinous exudation on the upper surface of its right lobe; it weighed sixty-nine ounces. The external surface of the spleen was covered with patches of fibrinous exudation; internally the organ was mahogany colored; it weighed eleven ounces and a half. The pancreas was healthy; weight five ounces. The left kidney weighed eight ounces and a half; its cortical substance was pale and fatty; the right kidney was similar to the left, and weighed seven ounces and a half. The small intestine was very much congested. The large intestine was also very much congested and greatly thickened, but there was no ulceration.

CASE 398.—Private Franklin McBeth, company E, 67th Pennsylvania volunteers; age 22; admitted February 3, 1864. [This man appears on the register of the regimental hospital of the 67th Pennsylvania volunteers, then near Brandy Station, Virginia, admitted November 14, 1863—typhoid fever; January 1, 1864, chronic diarrhœa is recorded—sent to general hospital February 3d.] Died, March 4, 1864. *Autopsy* twenty-two hours after death: Height five feet six inches; body much emaciated. The brain was slightly congested, otherwise normal; weight forty-eight ounces and a half. The trachea and bronchial tubes were normal. The lungs were also normal, with the exception of slight congestion of the left lung; weight of right lung eight ounces and a half, left lung fifteen ounces; the left pleural cavity contained two ounces of bloody serum. The heart was healthy, its valves perfect; weight five ounces and a half. The pericardium contained two drachms of serum. The

liver was healthy; weight forty-five ounces; the gall-bladder contained an ounce of bile. The spleen was of a dark-mahogany color; weight three ounces and a half. The pancreas was healthy; weight three ounces. The kidneys were apparently healthy; weight of right kidney six ounces and a half, left kidney five and a half. The bladder was considerably distended with urine. The œsophagus was normal. The stomach was moderately congested, its mucous membrane thickened. The duodenum was congested, and Brunner's glands were enlarged. Portions of the mucous membrane of the jejunum and ileum were congested. The solitary glands and Peyer's patches were thickened and very prominent, but there was no ulceration. The mucous membrane of the large intestine was thickened throughout, and studded with ulcerations of small size, none exceeding the third of an inch in diameter; some had apparently cicatrized, some were in the process of healing, while others seemed recent and extending; these ulcers were least abundant in the upper portion of the large intestine, the cæcum being nearly free from them; they were most plentiful in the sigmoid flexure and the rectum; the mucous membrane between the ulcers was dotted over with numerous little patches of pseudomembrane, which adhered quite firmly. The appendix vermiformis was capacious, its mucous lining thickened and congested.

CASE 399.—Private Greenleaf P. Foster, company K, 18th Massachusetts volunteers; age 36; admitted from the field February 3, 1864. Chronic diarrhœa. Died, March 4th, of delirium tremens. *Autopsy* eighteen hours after death: Height five feet six inches; rigor mortis well marked; body not much emaciated. The brain weighed forty-five ounces, and was apparently healthy; very little fluid was found in the ventricles. The lining membrane of the trachea was very much congested. There were numerous firm adhesions at the apex of the right lung; the lung weighed twenty-one ounces; it was very much congested throughout; in the posterior portion of its upper lobe there was a circumscribed patch about the size of a walnut, which was of a dark-mulberry color and sank in water; the left lung weighed twenty-one ounces; nearly the whole of its surface was coated by recent lymph, and the pleural sac contained forty-eight ounces of serum; the upper lobe of the left lung was congested, purple on section, and exuded a large amount of frothy fluid; the lower lobe was carnified. The pericardium contained an ounce and a half of fluid. The heart was apparently healthy, weight nine ounces; a large fibrinous clot was found in the right ventricle, and a very small venous clot in the left ventricle. The mucous membrane of the œsophagus was very pale. The stomach was well distended; its mucous membrane very soft and of a dusky-brown color. The intestines were much distended with gas; the mucous membrane of the duodenum and jejunum was of a very light color, nearly white; for about a foot of the upper part of the ileum, and about two feet of the lower portion, the mucous membrane was of a pinkish hue; the mucous membrane of the large intestine was of a dirty light-bluish color. The liver weighed seventy-one ounces; it was very friable; its capsule readily separated; its color a little lighter than natural. The pancreas was healthy, weight three ounces. The spleen weighed five ounces, was very firm, and of a light color. Both kidneys were healthy; the right weighed six ounces, the left seven ounces.—Acting Assistant Surgeon H. M. Dean.

CASE 400.—Private Michael Weider, company G, 1st Maryland volunteers; age 40; admitted from the field March 25, 1864. Acute dysentery. Died, March 31st. *Autopsy* four hours and a half after death: Height five feet six inches; body very much emaciated. Brain not examined. The left lung was healthy, and weighed eleven ounces and a half; the right lung weighed twenty-five ounces; the base of its lower lobe was in the third stage of pneumonia; the rest of the lung was normal. The pericardium contained half an ounce of serum. The heart was normal, and weighed seven ounces. The stomach and small intestines appeared to be healthy, with the exception of the last thirty inches of the ileum, in which the membrane was very vascular and coated with pseudomembranous lymph. The whole length of the large intestine was extensively ulcerated; the ulcers varied in size from a quarter of an inch to an inch and a half in diameter; most of them penetrated to the muscular coat; between the ulcers the mucous membrane was coated with pseudomembrane in many places. The spleen was healthy, and weighed four ounces. The pancreas was healthy, and weighed two ounces. The kidneys were also healthy; the right weighed five ounces, the left four.—Acting Assistant Surgeon H. E. Paine.

CASE 401.—Private Clarence C. Jenks, company A, 8th Illinois cavalry; age 29; admitted March 12, 1864. Intermittent fever. Died, April 4th, of epilepsy. *Autopsy* eighteen hours after death: Height five feet eleven inches; rigor mortis well marked; body somewhat emaciated. The brain weighed forty-nine ounces, and was quite soft. The right lung weighed twenty-three ounces and a half, the left sixteen and a half. The heart weighed eleven ounces. The pericardium contained two ounces of serum. The liver weighed seventy-five ounces and a half. The spleen weighed twenty-five ounces; the pancreas four ounces. The right kidney weighed seven ounces and a half, the left six and a half. The stomach was healthy. There were several patches of congestion in the small intestine, and in the last two feet of the ileum there were several ulcers in the process of cicatrization. Several cicatrizing ulcers were also observed in the colon, especially in the descending colon and sigmoid flexure; they varied from a line to half an inch in diameter.—Acting Assistant Surgeon H. M. Dean.

CASE 402.—Private Andrew King, company A, 8th Illinois cavalry; age 44; admitted April 6, 1864. Acute gastro-enteritis. About ten days before admission this man began to suffer from a looseness of his bowels. At first the evacuations were large and fæcal in character, but rapidly became more fluid in consistence, and assumed a fetid odor and yellowish color. Very soon after, the stomach became so irritable that little could be retained. A few days before admission he had a chill followed by increased febrile action, cough, and pain in the right side of the abdomen; the frequent evacuations, inability to retain nutriment, and severe abdominal pain which prevented sleep for several nights, rapidly wasted his strength and flesh. On admission he complained of severe pain in the stomach and abdomen, great thirst for cold drinks, frequent desire to evacuate the bowels, the stools being liquid, fetid, and of a yellowish color; weakness, and inability to sleep. He had cough, which was accompanied by a slight expectoration of yellow tenacious mucus, but which did not annoy him much. The physical signs indicated solidification of the lower lobe of the right lung, more marked posteriorly. The respirations were 26, the pulse 120 and feeble; the surface was cold, the extremities purple; the tongue was dry, with a heavy brownish fur in the centre, its edges being red. Ordered a sinapism to the epigastrium, and a powder containing ten grains of subnitrate of bismuth, one of

powdered opium, and one of powdered ginger, to be given every two hours; two drachms of brandy in ice-water every hour. April 8th: The stomach will not retain anything; the bowels are moved about once every two hours; considerable griping precedes and attends the stools; he asks for cold water constantly, but instantly vomits it again. Ordered half a grain of sulphate of morphia by enema after each stool; turpentine stupes to the abdomen. To allay the irritability of the stomach lime-water, creasote, chloroform, dilute nitric acid, opiates, bits of ice, &c., were by turns carefully tried without effect. The severity of the symptoms gradually increased, the patient rapidly emaciated, and notwithstanding he took, by enema, nearly a grain of sulphate of morphia hourly, for the last forty-eight hours of his life, sleep and freedom from pain could not be obtained. Died, April 11th, at 12 midnight. *Autopsy* nine hours after death: Rigor mortis marked; body considerably emaciated. The brain was normal, and weighed fifty-three ounces. The left lung was united to the thoracic walls throughout by old fibrous adhesions; it was healthy, and weighed fifteen ounces. The posterior portion of the lower lobe of the right lung and small portions of the upper and middle lobes were in the third stage of pneumonia, the rest of the lung healthy; the lung weighed forty-two ounces. The pericardium contained two ounces of serum. On the external surface of the heart near its apex was an opaque patch the size of a three-cent piece; the right auriculo-ventricular opening was somewhat dilated, four fingers being readily admitted; the walls of the left ventricle were somewhat thickened, but no valvular disease was discovered; the heart weighed fourteen ounces. The liver weighed seventy-seven ounces; the spleen seven; the pancreas three; the right kidney six, and the left seven and a half; all appeared to be normal. The mucous lining of the lower six inches of the œsophagus was eroded, fissured, and of a greenish-brown color, easily peeling from the subjacent connective tissue. The stomach was very vascular; its mucous membrane, which was of a dirty greenish-yellow color, was thickened, and presented numerous ecchymosed spots. The whole intestinal canal was very vascular, the vascularity increasing in intensity in the lower portion of the ileum, and thence to the anus; the lower two feet of the ileum and the whole of the large intestine were studded thickly with small recent ulcers, very few exceeding a pin's head in size.—Acting Assistant Surgeon William W. James.

CASE 403.—Private W. H. Gupton, company D, 44th North Carolina, (Confederate;) age 29; admitted December 17, 1863. Chronic diarrhœa. Died, April 21, 1864. *Autopsy:* Height six feet; body extremely emaciated. Brain not examined. Both lungs were adherent at their apices to the thoracic walls; there was considerable tuberculous solidification in the posterior part of the upper lobe and upper third of the lower lobe of the left lung; on section of the consolidated portion numerous small cavities were seen, which communicated with the bronchial tubes and with each other; they were filled with a yellowish somewhat fetid, purulent secretion, and were lined by a distinct smooth membrane; the superior lobe of the right lung was almost wholly solidified; at its apex was a cavity the size of a walnut, with several smaller ones communicating with it; these cavities closely resembled those in the opposite lung; the lower lobe was healthy; the right lung weighed twenty-four ounces, the left thirty ounces. The heart was healthy; weight eight ounces. The liver, spleen, pancreas, and kidneys were healthy; weight of liver fifty-three ounces; spleen ten ounces; pancreas two ounces; right kidney five ounces, left five and a half. The small intestine contained a considerable amount of tubercular (?) deposit, and was extensively ulcerated. In the large intestine were several ulcers, many in a state of cicatrization.—Acting Assistant Surgeon Henry E. Paine.

CASE 404.—Private Martin O'Conner, 39th company, 2d battalion Veteran Reserve Corps; age 57; admitted August 16, 1864. Chronic diarrhœa. Died, September 15th, of convulsions. *Autopsy* fourteen hours after death: The vessels of the brain were much congested; a small abscess, the size of a large pea, was found near the surface of the left hemisphere about an inch from the median line; with this exception the brain appeared to be normal. The trachea was lined with tenacious purulent sputa. The right lung weighed thirty-eight ounces; its lower lobe and the posterior portion of the upper lobe were in the stage of gray hepatization; the left lung weighed nineteen ounces. The heart weighed eight ounces and a half; its parenchyma and valves were normal; the right auricle contained a medium-sized fibrinous clot; no other clots were observed. The liver was of normal appearance, and weighed fifty-five ounces; the gall-bladder contained three ounces of molasses-colored bile. The spleen weighed five ounces and a half. The right kidney weighed five ounces, the left four and a half. The œsophagus was normal. [The condition of the rest of the alimentary canal is not recorded.]—Acting Assistant Surgeon H. M. Dean.

CASE 405.—Private James Long, company K, 4th New York artillery; age 37; admitted from the army of the Potomac August 24, 1864. Pleuro-pneumonia. Died, September 17th. *Autopsy* an hour and a half after death: The brain appeared to be normal. The right pleural sac was filled with serum mixed with pus, which coagulated on standing. The trachea was normal. The right lung was very much compressed, being about the size of the shut fist, and was covered by a thick layer of fibrin; on section it was found to be carnified, and a small abscess, about the size of a hazel-nut, was observed in its substance; it weighed ten ounces and a half; the left lung was apparently normal and weighed fifteen ounces. The œsophagus, stomach and small intestine were normal. The colon and cæcum were congested. The rectum was ulcerated in several places. The spleen weighed seven ounces and a half; its substance was firm. The liver weighed seventy-one ounces and a half; in its right lobe was an abscess about the size of a large hen-egg, the rest of the organ appeared to be normal; the gall-bladder contained twenty-two drachms of bile. Both kidneys appeared to be normal; the right weighed five ounces and a half, the left six and a half.—Acting Assistant Surgeon H. M. Dean.

CASE 406.—Private Harman Newton, 10th Massachusetts battery; age 35; admitted from the depot hospital of the 2d Corps July 30, 1864. Rheumatism and phthisis. The patient when received into the hospital was exceedingly debilitated; he was suffering with rheumatic pains in his lower extremities, and had also a severe cough, with free expectoration and diarrhœa. August 25th: Nausea and vomiting set in, followed by night-sweats and hectic fever. Died, September 18th, of phthisis.—Acting Assistant Surgeon G. C. Clarke. *Autopsy* five hours and a quarter after death: Height five feet nine inches; body very much emaciated, and covered with fine purpuric spots; no rigor mortis. The brain was normal, and weighed forty-six ounces and a half. There were firm pleuritic adhesions on the left side. The lower lobe of the right lung was considerably congested,

and on section a purulent fluid exuded from many of the small bronchial tubes; the middle and upper lobes were normal; there were several carnified spots about three-quarters of an inch in diameter in the lower lobe of the left lung, and on section a large quantity of frothy sanguineous fluid exuded; the upper lobe appeared to be normal; the right lung weighed twenty ounces, the left thirteen and a half. The heart was very small, weighing but five ounces and a half. The spleen weighed four ounces and a half. The liver was very much congested, and weighed forty-six ounces and a half. Both kidneys were congested; the right weighed four ounces and a half, the left five and a half. The œsophagus was normal. The cæcum and about three feet of the lower portion of the ileum were very much congested. At the sigmoid flexure of the colon there was an oval ulcer measuring two inches and three-quarters by two inches, its longest diameter being across the intestinal canal; its margin was very jagged and abrupt. There were several small ulcers in the lower portion of the rectum.—Acting Assistant Surgeon H. M. Dean. [No. 403, Medical Section, Army Medical Museum, is from this case; the specimen is the atrophied heart.]

CASE 407.—Private Gilbert Keenholtz, company D, 7th New York artillery; age 37; admitted from Alexandria, Virginia, September 19, 1864. Chronic diarrhœa and hepatitis. [This man appears on the register of the Augur hospital, near Alexandria, Virginia, admitted September 11th—remittent fever—sent to general hospital September 19th.] The patient stated that he had been sick about four months; he was very yellow and anæmic. Died, September 23d.—Acting Assistant Surgeon C. H. Burgess. *Autopsy* five hours and a half after death: Height five feet six inches; rigor mortis well marked; body well nourished; skin icteroid. The brain appeared to be normal, and weighed forty-seven ounces; there was a larger amount of fluid in the subarachnoid space than usual. The trachea contained a considerable quantity of yellowish-white sputa. On section of the right lung an abundance of yellowish-white frothy fluid exuded; the left lung appeared to be normal; the right lung weighed fourteen ounces and a half, the left thirteen ounces. The heart weighed nine ounces; its valves were normal; there was a mixed clot in its right cavities, in the left a small vermiform fibrinous clot. The spleen weighed only three ounces; on section it had a granular appearance. The liver weighed seventy-two ounces and a half; its left lobe was entirely destroyed by abscesses; the right lobe contained two abscesses, one about the size of a goose-egg, the other about the size of a hen-egg. Both kidneys were slightly congested; the right weighed five ounces and a half, the left six and a half. The œsophagus, stomach, and small intestine appeared to be normal. In the cæcum there were several large ulcers, the longest diameter of which was transverse to the length of the intestine; the remainder of the large intestine was very much congested.—Acting Assistant Surgeon H. M. Dean.

CASE 408.—Sergeant Frederick Brenner, company C, 15th New York artillery; age 50; admitted from the army of the Potomac October 7, 1864. Chronic diarrhœa. Died, October 10th. *Autopsy* ten hours and a half after death: Height five feet seven inches; rigor mortis well marked; body well supplied with fat. The brain weighed forty-three ounces. The lower lobes of both lungs were much congested, and a large amount of rust-colored frothy mucus exuded on section; the remaining lobes appeared to be normal; the right lung weighed twenty-one ounces, the left sixteen and a half. The heart and its valves were normal; it weighed eleven ounces; its right side contained a very large black clot, the left auricle a small one. The liver was congested, and weighed seventy-seven ounces; the gall-bladder contained seventeen drachms of very thick ropy bile. The spleen was light colored and soft; it weighed six ounces and a half. Both kidneys appeared to be normal; the right weighed six ounces, the left six and a half. The œsophagus, stomach and small intestine appeared to be normal. The mucous membrane of the large intestine was studded with ulcers, many of which were very deep.—Acting Assistant Surgeon H. M. Dean.

CASE 409.—Private J. F. Chipman, company E, 36th Wisconsin volunteers; age 36; admitted from the army of the Potomac August 30, 1864. Gunshot wound of the back of the left hand. Died, October 17th, of purpura and exhaustion. *Autopsy* next day: Height five feet eight inches; no rigor mortis; body very much emaciated. The brain appeared to be normal, and weighed forty-seven ounces and a half. On the left side of the larynx was an ulcer which penetrated through the mucous membrane to the hyoid bone, which was roughened as if carious. The lower lobes of both lungs were very much congested, and on section a large amount of frothy fluid of a rust-color exuded, but no part of the lobes would sink in water; the remaining lobes were normal; the right lung weighed sixteen ounces and a half, the left fifteen and a half. The heart and its valves were normal; it weighed eight ounces and a half; its right cavities were filled with a large dark clot; the left auricle contained a medium-sized black clot, the left ventricle a small vermiform one. The skin of the abdomen was studded with spots about a line in diameter, which resembled those seen when gunpowder has been deposited beneath the integument; there was quite a large amount of straw-colored fluid in the abdominal cavity, and a deposit of lymph on the peritoneum. The liver weighed thirty-eight ounces; it was of a dull slate-color externally, and on section appeared to be anæmic; its acini were not well marked; the gall-bladder contained twelve drachms of bile. The spleen weighed seven ounces. The right kidney was normal and weighed three ounces and a half, the left four ounces; the cortical substance of the left kidney was dark colored. The stomach appeared to be normal. The mucous membrane of the small intestine was very much congested, and in the ileum there were quite a number of old ulcers, many of which penetrated to the muscular coat. The large intestine was studded with ulcers resembling those seen in the ileum.—Acting Assistant Surgeon H. M. Dean.

CASE 410.—Private Chester Rasbeck, company A, 10th New York heavy artillery; age 20; admitted from regimental hospital September 28, 1864. Chronic diarrhœa and quotidian intermittent fever. [This man appears on the register of the regimental hospital of the 10th New York artillery, admitted January 13, 1864—small-pox—sent to small-pox hospital January 19th. He is borne on the register of the Kalorama small-pox hospital, Washington, D. C., admitted January 19th—variola—returned to duty January 25th. He again appears on the register of his regimental hospital, admitted January 26th—catarrh—returned to duty February 7th. No subsequent record of his case is found prior to his admission to Lincoln hospital.] The patient had violent chills every day for several days after admission, but they were controlled on the fourth day by the free use of quinine. He was also suffering from a profuse watery diarrhœa, having from fifteen to twenty stools daily. Quinine, astringents, and stimulants were employed without benefit. Died, October 26th.—Acting Assistant Surgeon W. E. Roberts. *Autopsy*

next day: Height five feet ten inches; body considerably emaciated. The brain was very firm; it weighed fifty-two ounces and a half. The larynx and trachea were normal. The lungs appeared to be normal when examined externally, but on section of their lower lobes a large amount of frothy rust-colored mucus exuded: the right lung weighed twenty-three ounces, the left twenty-seven ounces. The heart and its valves were normal; it weighed nine ounces and a half; its right side contained a large fibrinous clot; the left side was empty. The spleen was of a dark slate-color and very pulpy; it weighed fourteen ounces. The liver was of a dark-olive color. The kidneys were normal; the right weighed four ounces, the left four and a half. The large intestine was very much ulcerated. The rest of the alimentary canal was normal.—Acting Assistant Surgeon H. M. Dean.

CASE 411.—Private Andrew Kitchen, company D, 16th Michigan volunteers; age 18; admitted from the army of the Potomac September 20, 1864. Remittent fever. [This man appears on the register of the hospital of the 1st Division, 5th Corps, near Petersburg, Virginia, admitted September 9th—remittent fever—sent to general hospital September 16th. He appears on the register of the depot hospital of the 5th Corps, City Point, Virginia, admitted September 17th—intermittent fever—sent to general hospital September 19th.] Died, November 9th, of tetanus from intestinal irritation—(convulsions from meningitis?) *Autopsy* eleven hours and a half after death: Rigor mortis well marked; body much emaciated; the jaws more than ordinarily rigid. The membranes of the brain were much congested; on cutting through them about six ounces of fluid escaped; the brain-substance was softened, and the gray matter was in excess; each ventricle contained about two ounces of serum; the brain weighed forty ounces. The thoracic viscera were normal in appearance. The right lung weighed thirteen ounces and a half, the left thirteen ounces; the heart six ounces and a half. The stomach and small intestine were congested; the large intestine congested and ulcerated; the other abdominal viscera were normal. The liver weighed thirty ounces; the spleen four; the right kidney four, the left three and a half; the pancreas two and a half.—Acting Assistant Surgeon A. Ansell.

CASE 412.—Private Dominick Swartz, company K, 2d New York heavy artillery; age 49; admitted from the army of the Potomac November 14, 1864. Chronic diarrhœa. [This man appears on the register of the hospital of the 1st Division, 2d Corps, near Petersburg, Virginia, admitted October 29th—diarrhœa—sent to depot hospital November 5th. He appears on the register of the depot hospital of the 2d Corps, City Point, Virginia, admitted November 5th—diarrhœa—sent to general hospital November 12th.] Died, November 30th. *Autopsy* ten hours and a half after death: Rigor mortis well marked; body considerably emaciated. The brain was normal; weight fifty-five ounces; there was a larger amount of subarachnoidal fluid than normal, and the pia mater and arachnoid were semi-opaque. The larynx and trachea were normal. The upper lobe of the right lung was in the stage of gray hepatization, and was adherent to the thoracic parietes; the remaining lobes were normal; the right lung weighed twenty-two ounces; there were extensive pleuritic adhesions on the left side; the lower lobe of the left lung was very much congested, and some of its lobules were in the stage of red hepatization; the upper lobe was normal; the left lung weighed twenty-five ounces. The heart weighed nine ounces; the cavities of its right side were distended by a large mixed clot, which extended into the venæ cavæ and pulmonary arteries; the left side contained a small vermiform clot. The liver, spleen, and kidneys presented nothing abnormal; the liver weighed sixty-four ounces and a half; the spleen five and a half; the right kidney six and a half, the left six. The mucous membrane of the intestines was a little more vasular than usual, but presented no other evidence of disease.—Acting Assistant Surgeon H. M. Dean.

CASE 413.—Zachariah Trent, a teamster; age 40; admitted from the hospital at Giesboro' Point, Maryland, December 2, 1864. Consumption and œsophagismus. According to his own statement this man enlisted in the rebel service some three years ago, and served until a short time since, when he deserted at Lynchburg, Virginia, and entered the United States service as a driver. In 1860 he had measles, followed by a cough and expectoration, which continued for several months. Four years ago he was run over by a wagon, the wheel passing over his abdomen. He continued to suffer for some time from the effects of this injury. Of late he has had a cough, and for the last seven weeks difficulty of swallowing. At present his countenance is sallow, and he is much emaciated; he has some cough, with a moderate quantity of muco-purulent expectoration. There is dulness on percussion over the greater portion of the chest, but more marked in the axillary and subaxillary regions than in front. On auscultation, mucous and submucous rhonchus are heard over both lungs, with sibilant rhonchus in some portions. He complains a good deal of dysphagia, and is unable to swallow anything but small quantities of fluid. At times he is troubled with retching, ejecting an offensive yellow fluid; his bowels are regular, the urine normal in quantity; he lies indifferently on either side, but with the knees drawn up toward the chest; the abdomen is very tender on pressure. From the foregoing symptoms tubercular disease of the lungs was diagnosticated; but it was thought that there might also be a scirrhous affection of some portion of the alimentary canal. Efforts were made to administer fluid nutriment and stimulants, but without success. Died, December 5th.—Acting Assistant Surgeon T. S. Haynes. *Autopsy* the same day: Height five feet eight inches and a half; rigor mortis well marked; body very much emaciated; countenance of a light-bronze hue. The brain was normal, and weighed fifty ounces and a half. The mucous membrane of the pharynx was quite rough; the mucous membrane of the larynx and trachea was also very much roughened, apparently by minute ulcers. Both lungs were studded with tubercles from the size of a pin's head to that of a small pea. The heart and its valves were normal; it weighed seven ounces; its right side contained a very large black clot, the left side a very small amount of black blood. The liver, spleen, and kidneys were normal. The spleen weighed five ounces and a half; the liver seventy ounces; the right kidney four ounces and a half, the left five ounces. The mesenteric glands were very much enlarged and softened. There was tubercular ulceration of the small intestine and the cæcum.—Acting Assistant Surgeon H. M. Dean. [Nos. 426 to 432, Medical Section, Army Medical Museum, are from this case. No. 426 consists of the larynx, and part of the trachea with the thyroid body attached; the under surface of the epiglottis and the mucous membrane of the larynx and trachea present a number of superficial ulcers. No. 427 is a section of the upper lobe of the left lung infiltrated with small cheesy tubercles. No. 428 is from the upper portion of the jejunum; the specimen presents near its middle a large ulcer, the long diameter of which is transverse to the length of the intestinal canal; on the peritoneal surface opposite the ulcer there are a number of minute tubercles. No. 429 is taken from high up in the ileum, and presents

two similar ulcers. No. 430 is from just above the ileo-cæcal valve, and exhibits a slightly thickened Peyer's patch in which there are a number of small discrete ulcers and several small isolated ones, apparently seated in the solitary follicles. The villi are hypertrophied in this piece and in Nos. 428 and 429. No. 431 is a portion of the cæcum with the vermiform appendix; an irregular ragged ulceration surrounds the orifice of the appendix, the mucous membrane of which is ulcerated throughout; the cæcum presents several large irregular ulcers. No. 432 consists of the duodenum with the pancreas attached; a mass of enlarged mesenteric glands lies in front of the head of the pancreas; posteriorly a portion of the abdominal aorta may be seen, with a number of enlarged lymphatic glands adjoining.]

Case 414.—Private Amos Allen, company H, 105th Pennsylvania volunteers; age 21; admitted from City Point, Virginia, October 8, 1864. Acute diarrhœa. This case was complicated with pleuro-pneumonia. The patient was much emaciated. The diarrhœa was arrested by appropriate remedies, but the chest-symptoms proved fatal. The patient suffered but little pain. Died, December 8th.—Acting Assistant Surgeon A. M. Sherman. *Autopsy* eight hours after death: Height five feet eleven inches; rigor mortis not well marked; body considerably emaciated. The brain was normal; weight forty-two ounces and a half. The larynx and trachea were normal. The right pleural sac contained fourteen ounces of fluid and a considerable quantity of recently deposited lymph. The lower lobe of the right lung was hepatized, and had in its centre a cavity containing about two ounces of a quite black and very fetid fluid the odor of which was peculiar and almost intolerable; the other lobes were normal; the lung weighed twenty-five ounces; the lower lobe of the left lung was in the stage of red hepatization; the upper lobe was normal; the left lung weighed twenty-one ounces. The heart was normal; weight six ounces and a half; the left auricle contained a small black clot. The liver, externally and on section, was of a much darker color than usual; it weighed forty-nine ounces. The spleen weighed seven ounces and a half; the right kidney six ounces, the left four and a half; the right kidney was much congested. The œsophagus, stomach, and small intestine were normal, with the exception of three small ulcers in the lower portion of the ileum. The large intestine was studded with ulcers with sharp-cut edges and dark-brown bases.—Acting Assistant Surgeon H. M. Dean.

Case 415.—Private Albert McCann, company M, 32d Massachusetts volunteers; age 24; admitted from City Point, Virginia, December 16, 1864. Consumption. [This man appears on the report of the regimental hospital of the 32d Massachusetts volunteers as taken sick November 3d—remittent fever—sent to division hospital November 23d. He is borne on the register of the hospital of the 1st Division, 5th Corps, as admitted November 23d—diarrhœa—sent to depot hospital December 6th. He appears on the register of the depot hospital of the 5th Corps, City Point, Virginia, as admitted December 7th—debility—sent to general hospital December 15th.] Died, December 20th. *Autopsy* two hours after death: Rigor mortis not very well marked; body considerably emaciated. The brain weighed fifty-two ounces; there was a large quantity of sub-arachnoidal fluid; the meninges were semi-opaque from a slight deposit of lymph. The larynx and trachea were healthy. There were pleuritic adhesions on both sides. The right lung was normal in appearance, and weighed fourteen ounces and a half; the left lung weighed eleven ounces and a half; its bronchial tubes were inflamed. The heart weighed five ounces and a half and contained no clots; its valves were healthy. There were evidences of extensive peritonitis. The spleen was congested, its external surface covered with a deposit of lymph; it weighed six ounces and a half. The liver was excessively congested, and on incision a large amount of black blood exuded; it weighed forty-two ounces. Both kidneys were congested; the right weighed four ounces, the left four ounces and a half. The mucous membrane of the large and small intestines was very much congested.—Acting Assistant Surgeon H. M. Dean.

Case 416.—Private Lindsey Morris, company A, 140th Pennsylvania volunteers; age 20; admitted from the depot hospital of the 2d Corps, City Point, Virginia, November 14, 1864. Chronic diarrhœa and debility. This man was taken sick October 20, 1864. At the time of admission he was very much exhausted; extremely emaciated; had no appetite; pulse 110 and weak; urine scanty and light colored; bowels loose. Treatment: Quinine, beef-tea, and brandy. November 19th: He was attacked with vomiting, ejecting a greenish acrid fluid. Applied a blister to the epigastrium, and directed him to take, every four hours, a powder containing two grains of calomel, half a grain of opium, one and a half of quinine, and four of prepared chalk. November 24th: The vomiting still continues. Ordered enemata of quinine and beef-tea three times daily. December 1st: The abdomen is so tender that peritonitis is diagnosticated, and warm fomentations applied to the abdomen. December 4th: The patient lies constantly on his back; pulse 90 and weak. December 6th: Eight abscesses were recognized on the front of the abdomen, and being opened discharged freely. The discharge was kept up by warm poultices; at the same time the injections of beef-tea and quinine were continued, as the patient was still unable to keep anything on his stomach. December 10th: The discharge from the abscesses is lessening. Continued the warm applications over the abdomen. Died, December 22d. From the time this patient was admitted till his death there was constant nausea and vomiting; during the last few days the injections were not retained.—Acting Assistant Surgeon E. B. Harris. *Autopsy* sixteen hours after death: Rigor mortis well marked; body very much emaciated. On the surface of the abdomen there were a number of small punctures which led to little abscess cavities, none of which extended beneath the external oblique muscle or its tendon. The brain weighed forty-seven ounces and a half. The larynx, trachea and lungs were normal. The right lung weighed eighteen ounces, the left nine and a half. The heart was normal, weight nine ounces and a half; each ventricle contained a very small fibrinous clot. The spleen was normal. The liver weighed forty-nine ounces and a half; it was very much congested, and on section a large amount of dark blood exuded; the gall-bladder contained four ounces of very dark viscid bile. Both kidneys were apparently normal in texture, but large; the right weighed nine ounces and a half, and the left ten ounces. The lining membrane of the œsophagus was slightly congested, but the stomach appeared to be normal. Throughout the whole length of the small intestine the mucous membrane appeared to be inflamed, and in the lower half of the ileum it was studded with ulcers about a line in diameter. The mesenteric glands appeared to be perfectly normal, varying from the size of a pea to that of a very small almond. [The condition of the large intestine is not recorded.]—Acting Assistant Surgeon H. M. Dean.

CASE 417.—Private William Lloyd, company H, 48th Pennsylvania volunteers; age 27; admitted from City Point, Virginia, January 7, 1865. Chronic diarrhœa. [This man appears on the register of the hospital of the 2d Division, 9th Corps, admitted December 2, 1864—diarrhœa—sent to depot hospital December 7th. He is borne on the register of the depot hospital of the 9th Corps, City Point, Virginia, admitted December 7th—chronic diarrhœa—sent to general hospital January 5, 1865.] Died, January 11th. *Autopsy* fifteen hours after death: Height five feet four inches and a half; rigor mortis well marked; body much emaciated. The brain weighed forty-four ounces; its meninges were opaque, and there was a much larger quantity of subarachnoid fluid than normal. The larynx and trachea were normal. There were firm, but apparently recent, pleuritic adhesions on the left side. Both lungs were much congested, and weighed nineteen ounces each. The heart weighed seven ounces and a half; its right cavities contained a large opaque fibrinous clot; the left side contained a small vermiform clot. The spleen was light colored, and weighed but two ounces and a half. The liver appeared to be normal, and weighed fifty-five ounces and a half. The kidneys weighed four ounces each. The œsophagus, stomach and small intestine were normal, with the exception of the lower portion of the ileum, where Peyer's patches presented the shaven-beard appearance, and the mucous membrane was much congested. In the large intestine the mucous membrane was entirely destroyed by ulceration, some of the ulcers penetrating to the peritoneum.—Acting Assistant Surgeon H. M. Dean.

CASE 418.—Private James Pilock, company B, 20th Indiana volunteers; age 18; admitted from the depot hospital of the 2d Army Corps, City Point, Virginia, December 16, 1864. Chronic dysentery. Treatment: Tonics, alteratives, and counter-irritants. Died, January 12, 1865.—Acting Assistant Surgeon John Morris. *Autopsy* five hours after death: Height five feet seven inches; body rigid and very much emaciated. The larynx and trachea were normal. Both lungs were firmly adherent to the diaphragm, and presented evidences of slight bronchitis in their lower lobes; the right lung weighed eight ounces, the left eleven. The heart weighed six ounces and a half; its right side contained a very large fibrinous clot, the left side a long vermiform one. The liver, spleen, and kidneys appeared to be normal; the liver weighed fifty-one ounces and a half; the spleen five ounces; the kidneys four ounces each. The lower part of the small intestine was very much congested; a diverticulum, two inches long and half an inch in diameter, was found five feet and a half above the ileo-cæcal valve. The mucous membrane of the large intestine was studded with ulcers.—Acting Assistant Surgeon H. M. Dean.

CASE 419.—Sergeant Robert Smith, company C, 8th Maryland volunteers; age 23; admitted from the depot hospital of the 5th Corps, City Point, Virginia, January 18, 1865. Chronic diarrhœa. Died, January 26th. *Autopsy* the same day: Height five feet ten inches; rigor mortis well marked; body much emaciated. The brain weighed fifty-one ounces. The mucous membrane of the trachea and bronchial tubes was much congested, and of a dull-pink hue. Both lungs were considerably congested; the right lung weighed thirteen ounces, the left nineteen ounces. The heart weighed eight ounces. The spleen was normal, and weighed eight ounces. The liver was congested, quite a large amount of black blood exuding on section; it weighed fifty-three ounces. The kidneys appeared to be normal; the right weighed six ounces and a half, the left seven and a half. The œsophagus, stomach and duodenum appeared to be normal. The mucous membrane of the rest of the intestine was of a dark-red color, but no ulcers were observed.—Acting Assistant Surgeon H. M. Dean.

CASE 420.—Corporal Clem P. Johnson, company D, 140th Indiana volunteers; age 30; admitted as a convalescent from the general hospital at Jeffersonville, Indiana, March 1, 1865. Chronic diarrhœa. Died, March 9th, of pleuro-pneumonia. *Autopsy* nine hours after death: Height five feet eight inches; body considerably emaciated. The larynx was œdematous and somewhat congested. The right pleural cavity contained fourteen ounces of serum, the left pleural cavity ten ounces. There were pleuritic adhesions on both sides, which appeared to be old on the left side, recent on the right. The right lung weighed thirty-seven ounces; it was almost completely hepatized; in its upper lobe there were a number of purulent deposits; the left lung weighed thirty-four ounces and a half; its upper lobe was hepatized, its lower lobe congested. The heart weighed nine ounces; there were fibrinous clots in both ventricles. The pericardium did not contain an unusual amount of fluid. The liver weighed eighty-seven ounces, but was normal in appearance. The spleen weighed thirty-nine ounces and a half. The jejunum was somewhat congested in three or four places; the ileum congested, and in its lower part ulcerated. The ileo-cæcal valve was ulcerated, and dark colored, as if gangrenous. The upper part of the colon was ulcerated, lower down it presented nothing abnormal. The kidneys and pancreas appeared to be healthy.—Acting Assistant Surgeon E. B. Harris.

CASE 421.—Private Frank Hart, company I, 53d Pennsylvania volunteers; age 47; admitted from the depot hospital of the 2d Corps, City Point, Virginia, January 7, 1865. Chronic diarrhœa. Died, March 16, 1865, of pneumonia. *Autopsy* seventeen hours after death: Height five feet four inches; body much emaciated. The mucous membrane of the larynx and trachea was normal. The right lung weighed twenty-eight ounces; the posterior part of the upper lobe and the upper part of the lower lobe were in a state of congestion approaching red hepatization; the left lung weighed twelve ounces, and was normal; the right pleural sac contained four ounces of fluid, the left pleural sac five ounces. The mucous membrane of the stomach was slightly congested; that of the intestines decidedly so, the congestion increasing in intensity toward the lower part of the canal. The lower part of the ileum was slightly ulcerated. The coats of the large intestine were thickened, and the gut was very much contracted. The liver weighed eighty ounces and a half; the spleen three ounces; the kidneys three ounces each.—Acting Assistant Surgeon E. B. Harris.

CASE 422.—Private Robert F. Kincard, company B, 11th North Carolina regiment, (Confederate;) age 45; admitted from City Point, Virginia, April 24, 1865. Chronic diarrhœa. Taken sick April 6th, at Sailor's Creek. Died, May 3d. *Autopsy* the same day: There were slight pleuritic adhesions on both sides. Both lungs were congested; a cavity about one inch in diameter, and with firm walls, was found in the apex of the right lung. The small intestine was congested; the entire colon extensively ulcerated.—Acting Assistant Surgeon J. P. Arthur.

CASE 423.—Private Martin K. Hendrick, company G, 16th Maine volunteers; age 43; admitted from the depot hospital of the 5th Corps, City Point, Virginia, May 5, 1865. Acute diarrhœa. Died, May 14th. *Autopsy* the same day: All the thoracic

and abdominal viscera were healthy, except the intestines, particularly the large intestine, which was very much ulcerated throughout its entire length.—Acting Assistant Surgeon J. P. Arthur.

CASE 424.—Private Jackson Crowley, company H, 15th New York engineers; age 29; admitted from field hospital June 13, 1865. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 15th New York engineers as having been treated for diarrhœa from May 26th to June 13th.] Died, July 5th, of diphtheria. *Autopsy* the same day: Body not emaciated; throat much swollen, and dark colored externally. The epiglottis, larynx, and trachea as far as its bifurcation, were inflamed, congested, and in some places coated with false membrane, in others ulcerated. No other abnormal appearances were observed. [It does not appear that the abdominal viscera were examined.]—Acting Assistant Surgeon E. A. Van Nort.

The notes of the next five cases were forwarded, with the specimens, to the Army Medical Museum from CARVER HOSPITAL, Washington, D. C., Surgeon Oliver A. Judson, U. S. V., in charge:

CASE 425.—Private Granville Vanwagner, company D, 126th Ohio volunteers; admitted from the field hospital, army of the Potomac, July 4, 1864. Typhoid fever. [This man appears on the register of the regimental hospital of the 126th Ohio volunteers, admitted June 25th—fever—sent to depot hospital June 29th. He is borne on the register of the depot hospital of the 6th Corps, City Point, Virginia, admitted—bronchitis—sent to general hospital July 3d.] He was very much emaciated, and was suffering from symptoms resembling typhoid fever. His tongue was covered with a thick, dry, brown fur; teeth with dark sordes; bowels tympanitic. Petechiæ were observed on the chest and the upper portion of the abdomen. There was tenderness on pressure in the right hypochondriac region. The surface of the body was dry, but there was little abnormal heat. The diarrhœa was quite severe, but the stools were feculent, and contained no blood or mucus. After a few days the diarrhœa abated somewhat, the tongue appeared moist, and there seemed to be a decided improvement in the condition of the patient. July 25th: The diarrhœa became aggravated, the tongue again dry and dark colored. The patient became delirious, and died July 30th. The treatment consisted in the free use of turpentine emulsion, together with opium and tannic acid to check the diarrhœa. Brandy and sulphate of quinia was also given freely. The diet consisted of boiled milk, gruel, &c. *Autopsy* six hours after death: Body greatly emaciated; rigor mortis not marked. There were old pleuritic adhesions on both sides. The lungs were normal, with the exception of some slight congestion at the apex of the right lung. The pericardium contained two ounces of pinkish serum. The heart was normal and contained no clots. The liver was enlarged and pale; the gall-bladder nearly filled with bile. The spleen was dark colored, and measured eight inches by four, but appeared firm. The stomach was dilated and flabby; its mucous membrane thickened and softened. The solitary follicles of the jejunum were slightly enlarged; those of the ileum were enlarged to the size of pin-heads. The mucous membrane of the ileum was thickened and softened, and Peyer's glands were congested but not elevated. The colon was distended and thin; in the ascending colon were a number of ulcers; in the transverse colon, which made a bend downward toward the pubes, large ulcers with ragged edges were seen, some of which extended through the muscular coat; these ulcers increased in size toward the sigmoid flexure.—Acting Assistant Surgeon O. P. Sweet. [Nos. 416, 417, and 418, Medical Section, Army Medical Museum, are from this case. No. 416 is a portion of the ileum taken from just above the ileo-cæcal valve, with slight enlargement of the solitary follicles. No. 417 is a portion of the transverse colon of the same patient, which is quite thin, and presents a number of irregular oval ulcers. No. 418 is a portion of the descending colon, also quite thin, and presenting numerous ulcers which have coalesced, forming large erosions, which in several places penetrate to the peritoneum.]

CASE 426.—Private Peter Quackenbush, company E, 111th New York volunteers; age 48; admitted from the depot hospital of the 2d Army Corps, City Point, Virginia, July 5, 1864. Chronic diarrhœa. The patient had a senile look, and was considerably emaciated; pulse about 80; tongue moist but covered with a gray fur; anorexia; severe diarrhœa. He continued about the same until July 10th, when he began to improve, the diarrhœa being somewhat checked and his appetite better. July 26th, he was attacked by a severe pain in the right side, with dulness on percussion, and other evidence of pleurisy with effusion. The diarrhœa now became aggravated, the anorexia returned, and the patient died August 1st. Treatment: Opiates and astringents were freely given to relieve the diarrhœa, and stimulants were administered from the first. When pleurisy set in a blister was applied to the right side of the chest. Diet: Milk, beef-essence, &c. *Autopsy* four hours after death: The left lung was bound firmly to the chest by old pleuritic adhesions; its lower lobe was greatly congested; pleuritic adhesions, which seemed quite recent, existed also on the right side; the posterior portion of the right lung was in a state of hypostatic congestion; the right pleural cavity was about half full of fluid. The heart appeared to be normal; a partially washed clot was found in its right side; the pericardium contained about three ounces of fluid. The liver was enlarged, pale, and apparently fatty; the gall-bladder was filled with viscid bile. The spleen was enlarged and very soft. The kidneys were of about the normal size; their cortical substance appeared very pale. The mucous membrane of the stomach was thickened and congested; that of the small intestine was also congested, especially within three feet of the ileo-cæcal valve, where Peyer's patches were considerably thickened and presented a spongy appearance at their centres. In the ascending colon there were several large ulcers with ragged edges, which contained a quantity of black pigment; the mucous membrane was considerably thickened and softened; in the transverse colon these ulcers were less numerous and smaller; in the descending colon they again became larger.—Acting Assistant Surgeon O. P. Sweet. [Nos. 353 to 355, Medical Section, Army Medical Museum, are from this case. No. 353 is a portion of the ileum taken just above the ileo-cæcal valve, showing a slightly thickened Peyer's patch and some tumefaction of the solitary follicles. No. 354 is a portion of the ascending colon, presenting a number of oval ulcers with abraded edges, varying from the size of a pin-head to that of a five-cent piece. No. 355 is a portion of the transverse colon, presenting a number of minute follicular ulcers.]

CASE 427.—Private Walter Butler, company B, 56th Massachusetts volunteers; admitted from the field hospital of the 1st Division, 9th Corps, July 5, 1864. Typhoid fever. The patient was considerably emaciated; petechiæ were seen on his abdomen; his tongue was thickly coated in its centre with a dark fur; pulse about 120 per minute; slight diarrhœa. These symptoms seemed to yield readily to the ordinary treatment of typhoid fever. About July 20th, he was able to walk about the ward, slowly convalescing. From imprudence in eating and drinking he was again, July 25th, attacked with severe diarrhœa, which caused him to sink rapidly. He had now anorexia; red, dry tongue; pulse about 80. Treatment: Opiates and astringents to relieve the diarrhœa; brandy. Diet: Boiled milk, beef, beef-essence, &c. He became greatly emaciated, and died August 2d. *Autopsy* four hours after death: Emaciation great; rigor mortis slight. The right pleural cavity was obliterated by old adhesions; the areolar tissue in the anterior mediastinum was emphysematous. The lungs contained much black pigment, and their upper portion was congested. The right side of the heart contained a large fibrinous clot which adhered firmly to the tricuspid valve; there was no clot in the left side; the valves were healthy; the pericardium contained half an ounce of fluid. The liver appeared to be normal; the gall-bladder was nearly filled with bile. The spleen was about the normal size, pale, and very firm. The kidneys were normal. The suprarenal capsules were dark colored. The walls of the stomach were thin and pale. The small intestine appeared healthy down to about the middle of the ileum, below which the glands of Peyer were congested, the congestion increasing in intensity downward; the solitary follicles of the lower portion were enlarged. The mucous membrane of the transverse colon was thickened and softened, the thickness greatly increasing in the descending colon, sigmoid flexure, and rectum; the thickened membrane presented a peculiar spongy appearance; there were follicular ulcers throughout the colon, which, in the transverse colon especially, had coalesced into large eroding excavations.—Acting Assistant Surgeon O. P. Sweet. [Nos. 356 to 359, Medical Section, Army Medical Museum, are from this case. No. 356 is a portion of the ileum, with pin-head enlargement of the solitary follicles and two very slightly thickened Peyer's patches. No. 357 is from the ascending, No. 358 from the transverse, and No. 359 from the descending, colon; in these specimens the intestinal walls are somewhat thickened, and there are numerous follicular ulcers, which, in the transverse colon especially, have extended into irregularly oval excavations exposing the muscular coat; between the ulcers there is some adherent pseudomembrane.]

CASE 428.—Private Marvin Kellogg, company G, 2d New York heavy artillery; age 33; admitted from the depot hospital of the 2d Corps, City Point, Virginia, August 21, 1864. Chronic diarrhœa. The patient was greatly emaciated and had a jaundiced look. He had a severe diarrhœa, amounting to fifteen or twenty dejections during the twenty-four hours; his pulse was weak and easily compressed; his tongue was moist and thinly coated with gray fur. He continued in about this condition till August 25th, when the fæcal discharges became very frequent and involuntary. Treatment: Opiates and astringents, pills of opium and nux vomica, opiate enemata, &c.; brandy as a stimulant. Diet: Milk, chicken, beef-tea, beef-essence, &c. He died August 28th. *Autopsy:* Rigor mortis great; body greatly emaciated; there was a large collection of sordes on the teeth. The lungs were normal. The right side of the heart contained a fibrinous clot, the left side was filled with dark blood; the valves were healthy; the pericardium contained about two ounces of fluid. The liver was slightly enlarged and congested; the gall-bladder was filled with viscid bile. The spleen was dark colored, small and firm. The mucous membrane of the stomach was congested and red, presenting signs of severe inflammation about the cardiac orifice; the pyloric end of the organ was greatly contracted, the mucous membrane being thrown into large folds. The agminated glands in the lower portion of the ileum were congested, the congestion increasing, and dark spots appearing on the mucous membrane near the ileo-cæcal valve. The mucous membrane of the colon was congested, thickened and roughened with pseudomembrane; in the lower portion of the descending colon there were a number of small ulcers.—Acting Assistant Surgeon O. P. Sweet. [Nos. 401 and 402, Medical Section, Army Medical Museum, are from this case. No. 401 is a portion of the ileum, No. 402 of the descending colon. The mucous membrane of both is coated with pseudomembrane; in the colon there are a number of small follicular ulcers.]

CASE 429.—Private William H. Brookhall, company I, 26th Michigan volunteers; admitted from the depot hospital of the 2d Corps, City Point, Virginia, August 30, 1864. Acute dysentery. At the date of admission the patient was not greatly emaciated. He had been ill but a few days. His pulse was rapid; tongue covered with a dark dry fur. He had anorexia, frequent alvine dejections, which consisted chiefly of mucus and blood, and almost constant tenesmus. The disease progressed unchecked, and, September 5th, great gastric uneasiness set in; the stools were about ten or fifteen during the twenty-four hours, and contained large quantities of mucus and blood, which emitted a very offensive odor; there was severe pain in the abdomen, and continual tenesmus. September 8th: All the symptoms are aggravated; there are involuntary discharges of large quantities of bloody mucus; raving delirium has set in; the pulse is very feeble. The treatment consisted in the free administration of alcoholic stimulants, astringent and opiate enemata, with full doses of opium given at bed-time, &c. The diet consisted of milk, beef-tea, &c. He died September 9th. *Autopsy* eight hours after death: Emaciation slight; rigor mortis well marked. The right lung was slightly bound to the walls of the chest posteriorly by old adhesions; both lungs appeared to be normal. The pericardium contained two ounces of fluid. The right side of the heart contained a large fibrinous clot, the left side was empty; the valves appeared to be healthy. The liver was enlarged, soft and pale; the gall-bladder distended with bile. The spleen was enlarged, firm and of a dark slate-color. Both the cortical and medullary portions of the kidneys were pale, but the organs were normal in size. The mesenteric glands were enlarged. The stomach was dilated and flabby; its mucous membrane thickened and softened. The jejunum was healthy; in the ileum the mucous membrane was congested and dark colored, and its solitary follicles were enlarged, especially near the ileo-cæcal valve. In the large intestine the mucous membrane and the submucous cellular tissue were gangrenous; in the ascending colon the sloughs, of dark color and fetid odor, were separating, or had already separated, leaving the circular fibres of the muscular coat in view; in the transverse and descending colon the mucous membrane had nearly all sloughed away, and in places the sloughs appeared to extend nearly or quite through the muscular coat.—Acting Assistant Surgeon O. P. Sweet. [No. 409, Medical Section, Army Medical Museum, is from this case. It is a portion of the descending colon, showing large irregular diphtheritic ulcers which expose the muscular coat; the sloughing pseudomembrane hangs in shreds from the edges of the ulcers.]

The notes of the next four cases were forwarded, with the specimens, to the Army Medical Museum from EMORY HOSPITAL, Washington, D. C., Surgeon Nathaniel R. Moseley, U. S. V., in charge:

CASE 430.—Private Baldas Dill, company I, 1st Maryland volunteers; age 22; admitted from the field hospital of the 2d Division, 5th Army Corps, September 20, 1864. Chronic diarrhœa. Treatment: Astringents and stimulants. Died, September 23d. *Autopsy* same day: The colon and rectum were soft and ulcerated, the ulcers presenting a dark-greenish base; the mucous membrane between them was coated with pseudomembrane in patches. [There is no record of the condition of the other organs.]—Surgeon Nathaniel R. Moseley, U. S. V. [Nos. 367 and 368, Medical Section, Army Medical Museum, are from this case. No. 367 is a portion of the transverse, No. 368 of the descending, colon; both are somewhat thickened, and have had the greater part of their mucous membrane destroyed by large diphtheritic ulcers.]

CASE 431.—Private John Ordikirk, company K, 8th New York heavy artillery; age 16; admitted from the depot hospital of the 2d Corps, City Point, Virginia, September 15, 1864. Chronic diarrhœa. The patient was very weak and much emaciated. Ordered him to be kept at rest, and prescribed alteratives and astringents. There was some little improvement up to the 19th, when the stools became more frequent and the patient much weaker. Directed brandy and scalded milk; continued the astringents. Died, October 2d. *Autopsy* next day: The solitary follicles of the ileum were enlarged to the size of pin-heads, and some of them were ulcerated at their apices. In the large intestine there were numerous small follicular ulcers, between which the mucous surface was frosted with pseudomembrane. [There is no record of the condition of the other organs.]—Acting Assistant Surgeon W. H. Combs. [Nos. 395 to 397, Medical Section, Army Medical Museum, are from this case. No. 395 is a portion of the ileum, with the ileo-cæcal valve and part of the cæcum. The solitary follicles in the ileum are enlarged to the size of pin-heads, some of them presenting a minute point of ulceration at the apex. The mucous membrane of the cæcum is thickened and sprinkled with points of pseudomembrane; it also presents a few small follicular ulcers. No. 396 is a portion of the cæcum with the vermiform appendix; there are a number of small follicular ulcers in the mucous membrane of the appendix, and of the cæcum near its orifice. No. 397 is a portion of the sigmoid flexure and rectum of the same patient, with numerous punched-out extremely small ulcers, between which the mucous surface is frosted with pseudomembrane.]

CASE 432.—Private Richard Bagler, company H, 6th Ohio cavalry; age 47; admitted from the hospital of the Cavalry Corps, City Point, Virginia, November 14, 1864. Chronic diarrhœa. The patient was in an advanced stage of the disease. He was treated with astringents and stimulants, astringent enemata, &c. The discharges soon became involuntary, and he died November 18th. *Autopsy* next day, by Acting Assistant Surgeon Isaac M. Downs: Numerous follicular ulcers with dark colored bases were found throughout the colon; between them the mucous membrane was slightly frosted with pseudomembrane; the walls of the colon were thickened. [The condition of other organs is not recorded.]—Surgeon N. R. Moseley, U. S. V. [No. 438, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the transverse colon, presenting numerous large follicular ulcers, and somewhat frosted with pseudomembrane.]

CASE 433.—Private John Fulton, company B, 16th Pennsylvania cavalry; age 23; admitted from the hospital of the Cavalry Corps, City Point, Virginia, November 14, 1864. Intermittent fever and chronic diarrhœa. Treatment: November 15th: Quinine and a febrifuge mixture. November 30th: Quinine and opium. December 15th: Continue treatment; add stimulants and astringent enemata. The diet throughout consisted of milk and farinaceous food. Died, December 27th. *Autopsy* by Acting Assistant Surgeon L. M. Osmun: The whole large intestine was thickened, and presented numerous follicular ulcers, and quite a number of cysts about the size of peas; the mucous membrane between the ulcers was congested, and had shreds of pseudomembrane adherent to it. [The condition of the other organs is not recorded.]—Surgeon N. R. Moseley, U. S. V. [No. 527, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the thickened transverse colon, which presents a number of follicular ulcers, between which there is some adherent pseudomembrane. When first received at the museum a number of small cysts projected above the surface of the gut; in the alcohol these have collapsed, and the excavations thus made resemble the other ulcers.]

The notes of the next case were forwarded, with the specimens, from COLUMBIAN COLLEGE HOSPITAL, Washington, D. C., Surgeon Thomas R. Crosby, U. S. V., in charge:

CASE 434.—Private Jacob Hilgert, company E, 104th Pennsylvania volunteers; admitted from Stone hospital January 10, 1865. Diarrhœa and consumption. [This man is borne on the register of Stone hospital, Washington, D. C., admitted December 9, 1864—chronic bronchitis—sent to Columbian hospital January 10th.] He had a distressing diarrhœa, together with a severe cough, and expectorated large quantities of muco-purulent sputa streaked with blood. There was dulness on percussion over the upper third of the right lung, and tubular respiration was heard on both sides. Treatment: Cod-liver oil with six ounces of whiskey daily. Diet: Milk, beefsteak and toast. The cod-liver oil appeared to increase his diarrhœa, and, January 16th, fusel-oil in five-drop doses was substituted, to be taken in his whiskey. January 25th: The expectoration is more copious, and his strength is failing; appetite very poor; he has four or five stools daily. He died February 6th.—Acting Assistant Surgeon H. D. Vosburgh. *Autopsy* fourteen hours after death: Both lungs contained numerous minute tubercles; near the apex of the right lung there was a cavity about the size of an orange, and on the surface of the upper lobe of the left lung a large and much puckered cicatrix-like depression was observed; there were pleuritic adhesions on the right side. Both small and large intestines presented tubercular ulcers. The mesenteric glands were enlarged. [Nos. 480 to 487, Medical Section, Army Medical Museum, are from this case. No. 480 is the upper lobe of the right lung, the cut surface of which shows a large number of minute tubercles. At the top of the lobe there is a cavity the size of an orange, with distinct firm walls. No. 481 is the upper lobe of the left lung, presenting on its convex surface a large and much puckered cicatrix-like depression. No. 482 is a portion

of the upper part of the jejūnum, presenting three small tubercular ulcers. No. 483 is from the upper part of the ileum of the same patient, and presents a large oval tubercular ulcer the long diameter of which is transverse to the gut. No. 484 is from the lower part of the ileum of the same patient, and presents a Peyer's patch which is the seat of three small tubercular ulcers. No. 485 is the lower extremity of the ileum, with the ileo-cæcal valve and part of the cæcum; there is a transverse ulcer just above the valve, and the cæcum is thickened and ulcerated. No. 486 is the vermiform appendix, which is deeply ulcerated. No. 487 is a portion of the transverse colon, which is thickened, and presents a number of deep ulcers.]

The next case is from the case-book of STANTON HOSPITAL, Washington, D. C., Surgeon Benjamin B. Wilson, U. S. V., in charge:

CASE 435.—Private Flavius J. Garrigus, company K, 140th Indiana volunteers; age 24; admitted from the 23d Army Corps February 3, 1865. Chronic diarrhœa. The patient was very much emaciated. He has had diarrhœa for about two months, the number of passages varying from five to fifteen in the twenty-four hours. The stools are mucoid and watery, but contain no blood; at times the abdominal pain is very great. The treatment consisted chiefly in the use of opium combined with astringents, such as sulphate of copper, acetate of lead, tannin, &c. Stimulants were also used freely. Died, February 19th. *Autopsy* four hours after death: The heart and lungs were normal. The mucous membrane of the lower part of the small intestine was very much thickened, softened and congested, but Peyer's patches were healthy, and there was no ulceration. Portions of the mucous membrane of the colon were also inflamed, but not thickened nor ulcerated.—Acting Assistant Surgeon D. Webster Prentiss.

The notes of the next case were forwarded, with the specimen, from the REGIMENTAL HOSPITAL of the 8th Illinois cavalry, Washington, D. C., by Surgeon Abner Hard:

CASE 436.—Private Frederick Gewecke, company K, 8th Illinois cavalry; German; age 27; admitted to regimental hospital May 6, 1864. He had been under treatment in quarters for some time with diarrhœa alternating with constipation. His breath was very offensive, resembling emanations from putrid animal matter. Obstinate diarrhœa soon supervened, with fever of an adynamic type. This state continued, with anorexia and emaciation, until May 18th, when he had hæmorrhage of the bowels. The turpentine he was taking was then increased in quantity, and the hæmorrhage was checked by enemata of solution of the persulphate of iron and laudanum. It recurred, however, several times, and he died May 23d. *Autopsy:* The lungs, liver, spleen and kidneys were apparently healthy. The mucous membrane of the small intestine was softened and ulcerated in patches. The colon from the cæcum to the rectum was ragged with ulceration; there were more than twenty perforations, yet no fæcal matter had escaped into the peritoneal cavity, and there were few adhesions showing peritoneal inflammation.—[No. 322, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the thickened ascending colon, presenting a number of deep ulcers with ragged edges. Two of the ulcers have perforated.]

The next five cases were forwarded on medical descriptive lists from the FIRST DIVISION of the ALEXANDRIA HOSPITAL, Virginia, Surgeon Charles Page, U. S. A., in charge from the date of the first case until August 23, 1864; afterward Surgeon Edwin Bentley, U. S. V.:

CASE 437.—Private Israel Bush, company I, 46th Pennsylvania volunteers; age 33; admitted September 16, 1863. Dysentery. The patient has frequent bloody discharges from the bowels; pulse 100; tongue coated. He is very much reduced in flesh and strength; no appetite. To take every three hours a powder containing one-eighth of a grain of calomel, three grains of Dover's powder, two grains of tannic acid, and four grains of prepared chalk. September 18th: The discharges from the bowels are restrained; the patient is feeling more comfortable, but is very weak and has no appetite. September 20th: The bowels are moved from five to six times a day; pulse 100 per minute; tongue covered with a white fur. ℞. Nitrate of silver four grains, opium eight grains; make sixteen pills. Take one every four hours. Milk-punch. The dysenteric discharges, however, continued unchecked, and the patient gradually sank. Died, September 25th. *Autopsy* twelve hours after death: There was extensive peritoneal inflammation; the mucous membrane of the ileum and ascending colon was also inflamed, and the latter was extensively ulcerated. The mesenteric glands were enlarged.—Acting Assistant Surgeon John Flickinger.

CASE 438.—Private Alfred Taylor, company B, 121st Pennsylvania volunteers; admitted from the hospital of the 3d Division, 1st Corps, near Catlett's Station, Virginia, November 4, 1863. Diarrhœa. The patient was very much broken down, and said he had suffered from diarrhœa for some time. ℞. Dover's powder ten grains, nitrate of potassa four grains, calomel one grain; three times daily. Milk diet. November 6th: He had a chill followed by fever, cough, and uneasiness in the chest. ℞. Dover's powder twenty-five grains, sulphate of quinia fourteen grains, mercury with chalk twelve grains; make five powders. Take one every three hours. A mustard plaster to the chest. Flaxseed-tea and nitre to drink. November 7th: Cough frequent; expectoration scanty; skin dry; some pain in the right side of the chest. On auscultation over the seat of pain some crepitation was discovered. To take, three times daily, a powder containing six grains of Dover's powder, two of quinine, and three of powdered camphor; also two ounces of wine every four hours. November 8th, morning visit: Pulse 97; skin dry; expectoration scanty. Continue treatment. Apply a blister six inches by seven to the right side of the chest. He died during the afternoon. *Autopsy:* The lower part of the right lung was hepatized. The heart and left lung were normal. No disease was detected in the stomach or bowels. The liver and spleen appeared to be healthy.—Acting Assistant Surgeon James Robertson.

CASE 439.—Private Lewis Iagle, company D, 8th Maryland volunteers; age 50; admitted from the hospital of the 3d Division, 1st Corps, November 4, 1863. Dysentery. This patient was very feeble, and had but little stamina to resist disease. He continued to sink from the time of admission. The treatment consisted in the use of pills of opium, camphor, and blue mass, with milk-punch and other stimulants. After November 9th, turpentine emulsion was administered. Died, November 13th.

Autopsy: The heart and lungs were normal. The liver was healthy. Two large gall-stones were found in the gall-bladder. There was extensive inflammation of the colon.—Acting Assistant Surgeon James Robertson.

CASE 440.—Private Amos Stork, company A, U. S. Engineers; admitted from the army of the Potomac January 10, 1864. Diarrhœa. The patient was extremely emaciated, had no appetite, and was in a typhoid condition; his stools were small and fetid. There was no vomiting, and he did not complain. He died January 16th, at 6 P. M. *Autopsy:* The thoracic viscera were healthy, except that the heart was small. The stomach was normal. The mucous membrane of both the small and large intestine was ulcerated; in the jejunum there was an invagination about three inches long, and another rather larger in the ileum. The mesenteric glands were diseased. The spleen was enlarged. The liver and kidneys were normal; the gall-bladder was empty.—Acting Assistant Surgeon W. Leon Hammond. [No. 44, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the jejunum, which presents a well-marked invagination, but no evidences of peritoneal inflammation.]

CASE 441.—Private Emmanuel Straw, company I, 58th Pennsylvania volunteers; admitted from Washington street prison September 26, 1864. Chronic diarrhœa. This case was complicated with hemorrhoids. There was great irritability of the stomach from the time of admission. Died comatose, October 21st. *Autopsy* eight hours after death: Both lungs presented patches of black pigment superficially, but were otherwise healthy; old pleuritic adhesions connected the lower lobe of the right lung to the thoracic parietes. The liver was unusually large, and presented the nutmeg appearance. The small intestine was inflamed throughout; the colon extensively ulcerated. Kidneys fatty.

Of the next twenty-two cases the first three were from medical descriptive lists, the remainder from the case-book of the SECOND DIVISION of the ALEXANDRIA HOSPITAL, Virginia, Surgeon T. Rush Spencer, U. S. V., in charge from the date of the first case to September 27, 1864; afterward Surgeon Edwin Bentley, U. S. V. Nineteen of the autopsies were made and recorded in the case-book by Acting Assistant Surgeon Thomas Bowen:

CASE 442.—Private G. A. Wagner, company K, 150th New York volunteers; age 23; admitted September 17, 1863. Chronic diarrhœa. At the time of admission, besides diarrhœa, the patient had symptoms of pneumonia. He was much debilitated. To take, morning and evening, four grains of Dover's powder, half a drachm of subnitrate of bismuth, and five grains of calomel in one powder; milk diet. September 18th: The cough is slightly better, and the passages are less frequent. Treatment and diet continued. September 19th: The stools are less frequent, but are still watery; the cough continues. To take a teaspoonful of syrup of squill three times a day besides the powders. September 29th: Condition improving; stools still watery, but not frequent. To take twenty drops of the syrup of the iodide of iron three times a day; also tincture of cinchona. October 5th: Is again attacked with violent diarrhœa, having eight passages in the twenty-four hours. Renew the subnitrate of bismuth in half-drachm doses; milk diet. October 7th: Patient very low; passages ten per day. Continue the subnitrate of bismuth; also give enemata of tannic acid and opium. October 8th: The passages have decreased in number to five in the twenty-four hours, but are mixed with blood. Stop the bismuth. Take three grains of powdered opium twice a day; milk-punch. October 9th: Patient complains of severe pain in right iliac region; had five bloody passages in the last twenty-four hours. To take powders of tannic acid, calomel, and opium every three hours; a mustard plaster to the abdomen; milk-punch. October 10th: The patient lies in a state of stupor, pulse feeble and trembling. Died at 9 A. M. *Autopsy:* There was extensive inflammation of the ileum, cæcum, and colon.—Acting Assistant Surgeon Thomas H. Stillwell.

CASE 443.—Private Johnson Houghtailing, company E, 19th New York cavalry; age 22; admitted October 13, 1863. Chronic diarrhœa. This man had suffered with diarrhœa since the middle of May last. In June he had typhoid fever. He is now much emaciated and weakened, cannot raise his head from the pillow; tongue coated with a thin brown coat, which is broken off in spots, showing a red dry surface beneath; has fifteen to twenty stools a day, with considerable tormina; there is a good deal of tenderness along the line of the colon; pulse 60 and full; no appetite. To take a pill containing a grain of opium and two grains of tannic acid every four hours; four ounces of cherry-brandy daily. October 15th: Had only seven passages in the last twenty-four hours; appears to be improving; can raise up in bed. To take a drachm of subnitrate of bismuth during the day, in three doses; milk diet; cherry-brandy as before. October 16th: Has a voracious appetite, which needs to be carefully regulated. Continue treatment. Substitute for the brandy two ounces of egg-nog every four hours. October 19th: Has had no movement of the bowels during the last twenty-four hours; pulse 64, full; appetite good; strength increasing rapidly. To take thirty drops of the tincture of the chloride of iron every five hours. October 20th: Bowels have not moved yet. Complains of a sense of fulness in the head and dizziness. Prescribed a laxative. October 21st: The medicine has operated on the bowels. The patient says he feels uncommonly well; appetite very good. To take quinine and whiskey as a tonic, with tincture of the chloride of iron; egg-nog; extra diet. October 22d: Sat up some time yesterday; bowels moved once. Continue treatment. October 23d: Said he felt quite well; had but two natural looking movements of the bowels in the last twenty-four hours; was able, with a little help, to get up to use the vessel. About 9.30 A. M. his breathing suddenly became very short and rapid, and he died in a few moments, without a struggle or effort to speak. *Autopsy* eight hours after death: The brain, lungs and heart appeared to be quite natural, except that perhaps the blood-vessels of the brain were a little fuller of blood than usual. The liver was rather large and excessively congested; otherwise its appearance was healthy. The spleen was also large and in a highly congested state. The stomach was healthy. There was extensive ulceration of the intestines, both large and small, and considerable thickening of the mucous membrane of the colon. The kidneys were healthy. Nothing was found to account for the sudden death of the patient.—Acting Assistant Surgeon A. Walter Tryon.

CASE 444.—Private Edward B. Chessman, company H, 32d Massachusetts volunteers; age 34; admitted December 5, 1863. Chronic diarrhœa. The patient had been sick nine weeks, having on an average eight passages per day; his appetite was

poor; he was very weak and greatly emaciated. Treatment: Tannic acid and opium, tincture of the chloride of iron, whiskey. December 9th: The diarrhœa is decreasing; he has now about four passages per day. Treatment continued. December 11th: Diarrhœa nearly controlled. December 15th: Diarrhœa has again returned; passages eight per day and painful. Complains of constant abdominal pain. Apply a mustard poultice; acetate of lead and opium. December 19th: The diarrhœa continues unchecked. The patient is losing strength. Died, December 27th. *Autopsy:* The lungs were congested, but contained no tubercles. The mucous membrane of both small and large intestine was inflamed and thickened.—Acting Assistant Surgeon Thomas H. Stillwell.

CASE 445.—Private Adelbert Caywood, company A, 24th New York cavalry; age 18; admitted from City Point, Virginia, October 2, 1864. Chronic diarrhœa. Died, October 25th. *Autopsy* twenty-four hours after death: Rigor mortis great; body very much emaciated. Head, neck and spinal column not examined. The pericardium contained half an ounce of clear serum. The heart was rather smaller than usual, its structure normal, although a little pale; all the valves closed perfectly, but they were somewhat attenuated; both auricles and ventricles contained small firm clots. The right pleural cavity contained an ounce of bloody serum; there were no adhesions between the pulmonary and costal pleura on either side, but the lobes of the right lung were interadherent. The left lung was pale, its structure normal; the right lung was congested, and portions of its upper and lower lobes, anteriorly, were in the stage of gray hepatization. The bronchi contained some muco-purulent matter, but their mucous membrane was normal; the bronchial glands were healthy with the exception of one, which contained a deposit of calcareous matter. The mucous membrane of the stomach was slightly congested. The duodenum was normal. The small intestine was congested in regions through its whole tract, but not ulcerated. The large intestine was contracted, thickened, and congested from the cæcum to the rectum, but there were no ulcers present. The liver was of medium size, its structure normal; the gall-bladder contained an ounce of very dark bile. The pancreas and spleen were normal. The kidneys apparently healthy in structure, but pale; the bladder contained about eight ounces of urine.—Acting Assistant Surgeon Thomas Bowen.

CASE 446.—Private James K. Foltz, company B, 60th Ohio volunteers; age 17; admitted from the field October 12, 1864. Chronic diarrhœa. [This man appears on the register of the depot hospital of the 9th Corps, City Point, Virginia, admitted September 1st—rheumatism and diarrhœa; no disposition.] Died, October 27th. *Autopsy* forty-eight hours after death: Rigor mortis great; body extremely emaciated; bed-sores posteriorly. Head, neck and spinal column not examined. The left pleural cavity contained an ounce of fluid, and there was a recent deposit of lymph on the left lung posteriorly; a small deposit of tubercle was observed in the lower lobe of the left lung; the lower lobe of the right lung was in the last stage of pneumonia; its structure broke down easily when crushed between the fingers; it was adherent to the costal pleura. The heart and pericardium were normal. The liver was normal; the gall-bladder contained about two drachms of bile. The spleen and pancreas were normal. The mucous membrane of the stomach and jejunum was quite healthy; that of the lower part of the ileum, colon, and rectum very much inflamed, but not ulcerated, nor were there any ulcerations in Peyer's patches. The mesenteric glands were very dark colored. The kidneys were normal; the bladder empty.—Acting Assistant Surgeon Thomas Bowen.

CASE 447.—Private George Stewart, company F, 4th New York artillery; age 45; admitted from the field October 21, 1864. Chronic diarrhœa. [This man appears upon the register of the depot hospital of the 2d Corps, City Point, Virginia, admitted October 6th—chronic diarrhœa—sent to general hospital October 20th.] Died, November 1st. *Autopsy* fifty-two hours after death: Rigor mortis very slight; body emaciated; slight suggillation posteriorly. Head, neck and spinal column not examined. The left pleural cavity contained about an ounce of fluid. The left lung was normal; the apex of the right lung was adherent posteriorly to the costal pleura; the lobes of the lung interadherent; the lower lobe hepatized posteriorly. The pericardium contained two drachms of fluid. The heart was normal. The spleen, pancreas and liver were normal; the gall-bladder contained about an ounce of bile. The left suprarenal capsule was enlarged and softened. The left kidney, dark externally, congested internally, had six small abscesses in its cortical substance. The right suprarenal capsule was softened. The right kidney was similar to the left, except that it had only two small abscesses in its substance; its pelvis was congested, and the corresponding ureter filled with a purulent fluid. The bladder was full of urine; its mucous coat seemed thickened. The mucous membrane of the stomach was dark colored; that of the small intestine congested in patches; that of the colon inflamed and very dark colored; that of the rectum very much thickened and extensively ulcerated.—Acting Assistant Surgeon Thomas Bowen.

CASE 448.—Private Monroe Ungers, company B, 50th Pennsylvania volunteers; age 18; admitted from the field August 10, 1864. Chronic diarrhœa. [This man is borne on the register of the depot hospital of the 9th Corps, City Point, Virginia, admitted August 3d—remittent fever; no disposition.] Died, November 1st. *Autopsy* thirteen hours after death: Rigor mortis great; body extremely emaciated; slight suggillation posteriorly. Head, neck and spinal column not examined. There were extensive old adhesions posteriorly between the lower lobe of the left lung and the costal pleura; the right pleural cavity contained an ounce of serous fluid; the left lung was healthy; the right healthy anteriorly, but posteriorly presented the appearances of gray hepatization; on the posterior surface of the lower lobe was a deposit of recent lymph about an inch in diameter. The pericardium contained two ounces of serum. The heart was very small, weighing about four ounces; its structure was healthy although pale. The cavities of both sides contained small, firm, white clots. The stomach was normal. The small intestine was congested throughout its whole extent, and very much inflamed near the ileo-cæcal valve; the large intestine inflamed and ulcerated in spots. The liver was congested; the gall-bladder contained an ounce and a half of yellow bile. The pancreas was normal. The kidneys were of a darker color than usual; the bladder contained about an ounce of urine.—Acting Assistant Surgeon Thomas Bowen.

CASE 449.—Private Frederick Rockstadt, company G, 204th Pennsylvania volunteers; age 46; admitted from regimental hospital October 28, 1864. Chronic diarrhœa. Died, November 1st. *Autopsy* twenty-four hours after death: Rigor mortis great; body emaciated; slight suggillation posteriorly. Head, neck, and spinal column not examined. The pericardium contained about two drachms of fluid. The heart was normal in size and structure, its valves healthy; the right auricle contained

a large firm clot; smaller clots of the same character were found in each of the other cavities; the large arteries and veins contained a small quantity of dark blood. There were extensive old pleuritic adhesions on both sides. The left lung was very much congested, and scarcely crepitated when squeezed; the right lung was in the stage of gray hepatization. The bronchial glands were normal. The great omentum was contracted, thickened, and adherent to the small intestine. The parietal surface of the peritoneum was covered with a deposit of lymph; the peritoneal cavity contained three ounces of fluid. The stomach was filled with a yellow fluid which had a fæcal odor. The peritoneum covering the small intestine was inflamed, and the knuckles of intestine were adherent to each other and to the parietal peritoneum by recent deposits of lymph. The mucous membrane of the small intestine was healthy; the colon inflamed and ulcerated; one of the ulcers near the sigmoid flexure had perforated; the rectum was perfectly disorganized, soft, thickened and dark colored. The liver was softer and darker than usual, and filled with small abscesses; about twenty of these were counted, varying in size from a pea to a walnut; the gall-bladder contained about two ounces of bile. The pancreas was normal. The spleen softened. The kidneys and ureters normal; the bladder filled with urine.—Acting Assistant Surgeon Thomas Bowen.

CASE 450.—Private William C. Sweeney, company A, 73d New York volunteers; age 39; admitted from the depot hospital of the 2d Corps, City Point, Virginia, November 2, 1864. Chronic diarrhœa. Died, November 3d. *Autopsy* twenty hours after death: Rigor mortis moderate; body very much emaciated; slight suggillation posteriorly. Head, neck and spinal column not examined. There were firm and extensive old pleuritic adhesions on both sides. The posterior portion of the lower lobe of the left lung was in the stage of red hepatization; in the apex of the right lung was a deposit of tubercle. The bronchial glands were enlarged and somewhat softened. The pericardium contained two ounces of fluid. The heart was normal. The omentum was congested. The liver was normal; the gall-bladder contained an ounce and a half of bile. The spleen was very small, but otherwise normal. The pancreas normal. The mucous membrane of the small intestine was very much congested, while that of the colon and rectum was inflamed, thickened, and ulcerated through its whole extent. The kidneys and bladder were normal.—Acting Assistant Surgeon Thomas Bowen.

CASE 451.—Private John F. McGauhey, company M, 21st Pennsylvania cavalry; age 18; admitted from the field October 12, 1864. Chronic diarrhœa. Died, November 8th. *Autopsy* thirty-eight hours after death: Rigor mortis very slight; body very much emaciated; slight suggillation posteriorly and on the abdomen. Head, neck and spinal column not examined. The left pleural cavity contained two, the right three, ounces of bloody serum. There were old pleuritic adhesions on the right side. There were deposits of tubercle in the upper lobes of both lungs; the lower lobes were in the stage of gray hepatization. The pericardium contained two drachms of serum. The heart was normal. The great omentum was very much congested. The liver was normal; the gall-bladder contained about three drachms of bile. The spleen and pancreas were normal. The kidneys were normal in size, but their cortical substance was very pale and had a fatty appearance. The stomach and duodenum were normal. Both the small and the large intestine were very red externally. The mucous membrane of the jejunum and ileum was congested, inflamed in patches, and there were several ulcers in the lower part of the ileum, which were not situated in Peyer's patches. The mucous membrane of the colon and rectum was thickened and inflamed.—Acting Assistant Surgeon Thomas Bowen.

CASE 452.—Private Oliver Bradley, company I, 179th New York volunteers; age 39; admitted from the field October 21, 1864. Chronic diarrhœa. [This man appears on the register of the hospital of the 2d Division, 9th Corps, admitted October 12th—typhoid fever—sent to depot hospital October 18th. He is borne on the register of the depot hospital of the 9th Corps, City Point, Virginia, admitted October 18th—chronic diarrhœa—sent to general hospital October 20th.] Died, November 11th, of typhoid fever. *Autopsy* fourteen hours after death: Rigor mortis moderate; body much emaciated; suggillation posteriorly. The dura mater was normal; there was half an ounce of serum in the subarachnoid space. The brain and pia mater were normal. Neck and spinal column not examined. The pericardium contained an ounce of clear fluid. The heart and its valves were normal; small fibrinous clots were found in both auricles and ventricles. There were slight adhesions between the base of the left lung and the diaphragm; the upper lobe of the left lung was normal, its lower lobe congested posteriorly; the right lung was normal. Three of the bronchial glands were very large, and contained an abundant deposit of calcareous matter. The liver was enlarged, but its structure seemed normal; the gall-bladder contained an ounce and a half of bile. The spleen, pancreas, mesenteric glands, kidneys, stomach, duodenum, and jejunum were normal. The mucous coat of the ileum presented several patches of inflammation. There were two ulcers in the upper part of the colon, which was otherwise normal. The rectum was inflamed.—Acting Assistant Surgeon Thomas Bowen.

CASE 453.—Private Henry Brady, company and regiment not recorded; admitted from Sanitary lodge November 12, 1864. Chronic diarrhœa. Died, November 13th. *Autopsy* fourteen hours after death: Great rigor mortis; body emaciated; an old cicatrix in the right iliac region. The subarachnoid space contained half an ounce of clear serum; the brain was normal. Neck and spinal column not examined. There were old pleuritic adhesions on both sides. The left pleural sac contained two ounces of serum. The posterior part of the lower lobe of the left lung was in the first stage of pneumonia, a small portion of it hepatized; the right lung was normal anteriorly, congested posteriorly. The pericardium contained half an ounce of serum. The heart was normal. The spleen was twice the usual size, but apparently normal in structure. The pancreas and liver normal; the gall-bladder contained an ounce of bile. The kidneys were normal; the bladder contained a pint and a half of urine. The mesenteric glands were a little darker than usual. The stomach and small intestine were normal. The descending colon and rectum were contracted, their mucous coat very much thickened and extensively ulcerated.—Acting Assistant Surgeon Thomas Bowen.

CASE 454.—Private Jeremiah Grinder, company H, 6th Pennsylvania heavy artillery; age 22; admitted from the field November 14, 1864. Cholera morbus. Died, November 15th. *Autopsy* twenty-eight hours after death: Rigor mortis very great; body muscular, well developed; no emaciation; extensive suggillation posteriorly. Head, neck and spinal column not examined. There were slight pleuritic adhesions posteriorly on both sides. Both lungs were engorged with blood, and did not

collapse when the sternum was removed. The heart was normal; there were large, very firm yellow clots in both auricles, and small ones in both ventricles; the auricular clot on the left side extended about six inches into the branches of the left pulmonary veins; these veins emptied into the heart by a single opening. The omentum was congested. The liver was large, but otherwise healthy; the gall-bladder contained about an ounce of dark bile. The spleen was normal. The pancreas a little congested, but otherwise healthy. Both kidneys were congested. The mesenteric glands were somewhat congested and enlarged. The mucous membrane of the ileum, for twelve inches from the ileo-cæcal valve, was thickened, inflamed, and ulcerated; it was very dark colored, and appeared almost gangrenous in many places. The mucous membrane of the colon and rectum was inflamed and ulcerated; the ulcers had ragged edges, and were arranged in narrow bands around the circumference of the gut; in other parts of the mucous membrane there were whitish deposits of pseudomembranous lymph.—Acting Assistant Surgeon Thomas Bowen.

CASE 455.—Private Thomas W. Martin, company I, 67th Pennsylvania volunteers; age 23; admitted from the field August 10, 1864. Chronic diarrhœa. [This man appears on the register of the regimental hospital of the 67th Pennsylvania volunteers, admitted April 7, 1864—catarrh—sent to general hospital April 20th. He is borne on the register of the Lincoln hospital, Washington, D. C., admitted April 21st—chronic diarrhœa—sent to Philadelphia May 3d. The register of the Mower hospital, Philadelphia, Pennsylvania, reports him admitted May 4th—chronic diarrhœa—returned to duty June 24th. He next appears on the register of the depot hospital of the 6th Corps, City Point, Virginia, admitted July 6th—chronic diarrhœa—sent to general hospital August 9th.] Died, November 16th. *Autopsy* twenty-four hours after death: Rigor mortis very great; body very much emaciated; slight suggillation posteriorly. Head, neck, and spinal column not examined. There were firm, old pleuritic adhesions on both sides. Both lungs contained extensive deposits of tubercle, which were found in all parts, but most abundantly in the upper lobes, in which there were also two or three cavities the size of small nutmegs. An extensive deposit of miliary tubercles was observed on the surface of the left costal pleura. The bronchial glands were very much enlarged. The pericardium contained about two drachms of serum. The heart and its valves were normal; both auricles were filled with black blood. The great omentum was thickened, contained deposits supposed to be tubercular, and was adherent to the small intestine and parietal peritoneum. Deposits of black pigment were observed on the parietal peritoneum and on the outer surface of the intestines; in the latter case they were associated with a deposit of small tubercles; the knuckles of small intestine were interadherent. The anterior portion of the liver was coated with recent lymph; the organ was normal in size but pale, and under the microscope appeared to be fatty; the gall-bladder was nearly empty. The spleen and pancreas were normal. Both kidneys were slightly congested. The mesenteric glands were enlarged and tuberculous. The mucous membrane of the stomach and duodenum was healthy. Large ulcers were scattered through the whole extent of the jejunum, ileum, and colon; they were most abundant in the lower part of the ileum, were of oval form, and had thickened, ragged, indurated edges; some of them were apparently healing, and the mucous coat around these was puckered up in small folds radiating from the ulcers.—Acting Assistant Surgeon Thomas Bowen.

CASE 456.—Private Isaac Koonts, company K, 204th Pennsylvania volunteers; age 44; admitted from regimental hospital October 28, 1864. Remittent fever. Died, November 17th, of chronic diarrhœa. *Autopsy* forty-one hours after death: Rigor mortis moderate; body not much emaciated; suggillation posteriorly. Head, neck and spinal column not examined. There were no pleuritic adhesions on either side. The right lung and the upper lobe of the left were normal; the lower lobe of the left lung was in the last stage of pneumonia. The pericardium contained two drachms of fluid. The heart was normal. There were but nine attached and three floating ribs, one of the latter being about two inches long. The great omentum was very fat. The intestines were filled with gas. The liver was a little enlarged, and paler than usual. The spleen and pancreas were normal. The mesenteric glands were dark colored, and a little enlarged. The mucous membrane of the stomach, duodenum, and jejunum was normal. Peyer's patches were very dark in the upper part of the ileum, but not thickened or ulcerated; in the lower part they were slightly thickened, ulcerated, and apparently undergoing the healing process. The colon was much thickened, blackened, and ulcerated. The rectum was still more extensively ulcerated. The kidneys were normal; the bladder contained half a pint of urine.—Acting Assistant Surgeon Thomas Bowen.

CASE 457.—Private Azro A. Shippy, company E, 2d United States sharpshooters; age 41; admitted from the depot hospital of the 2d Corps, City Point, Virginia, November 2, 1864. Chronic diarrhœa. Died, November 20th, of pneumonia. *Autopsy* ten hours after death: Rigor mortis very great; body very much emaciated. Head, neck, and spinal column not examined. There were extensive pleuritic adhesions on the right side. A few small tubercles, not softened, were observed in the apex of the right lung; the lower lobe was generally in the first stage of pneumonia, but small portions of it were hepatized; there were old pleuritic adhesions on the left side posteriorly; the upper lobe of the left lung was normal, the lower lobe in the same condition as the lower lobe of the right lung. The pericardium contained about two drachms of serum. The heart was normal. The liver was normal; the gall-bladder contained about half an ounce of bile. The spleen was slightly enlarged. The pancreas and mesenteric glands normal. The cortical substance of the kidneys was pale. The mucous membrane of the stomach was congested; that of the jejunum normal; that of the lower part of the ileum thickened and very much inflamed. The mucous membrane of the colon and rectum was thickened, inflamed, and ulcerated in several places. Acting Assistant Surgeon Thomas Bowen.

CASE 458.—Private George W. Doremire, company M, 2d Pennsylvania cavalry; age 19; admitted from Soldiers' Rest October 5, 1864. Chronic diarrhœa. [This man appears on the hospital register of the Soldiers' Rest, Alexandria, Virginia, admitted June 28th—chronic diarrhœa; no disposition.] Died, November 28th. *Autopsy* fourteen hours after death: Rigor mortis great; body very much emaciated; sordes on teeth. Head, neck and spinal column not examined. The pericardium contained about a drachm of serum. The heart was small, but normal in position and structure, except that the foramen ovale was not perfectly closed; the opening was very oblique, and its edges overlapped so that there could be no admixture of blood in the auricles. There were small dark clots in both auricles and ventricles. There were old pleuritic adhesions on the left side

posteriorly, and at the apex of the lung. The lower lobe of the left lung generally was in the first stage of pneumonia; a small portion of it was hepatized; the lobes of the right lung were adherent to each other; the lower lobe was in the same condition as the corresponding lobe of the left lung, except that its inferior margins were coated with recent lymph. The mucous membrane of the stomach, duodenum, and jejunum was normal; that of the lower part of the ileum was congested in patches, while in the cæcum, colon, and rectum the mucous membrane was much inflamed. There were five ulcers, the size of grains of barley, in the rectum. The liver, pancreas, and kidneys were normal. The spleen was indurated, and weighed but about two ounces. Acting Assistant Surgeon Thomas Bowen.

CASE 459.—Corporal John Magher, company E, 88th New York volunteers; age 24; admitted from the field October 21, 1864. Chronic diarrhœa. [This man appears on the register of the depot hospital of the 2d Corps, City Point, Virginia, admitted September 24th—chronic diarrhœa—sent to general hospital October 20th.] Died, November 29th. *Autopsy* nine hours after death: Rigor mortis moderate; body emaciated; axillary and cervical glands very much enlarged; old ulcers (apparently chancres) on the penis; extensive suggillation posteriorly. The subarachnoid space contained an ounce of serum; the pia mater was injected; the brain was normal; fluid blood escaped from the sinuses when they were opened, and coagulated as perfectly as blood drawn during life. Neck and spinal column not examined. There were extensive firm, old pleuritic adhesions on both sides, and about four ounces of serum in each pleural cavity. In the apex of each lung was a deposit of cretefied tubercles; the lower lobes of both lungs were dark, congested, indurated, and crepitated very little when pressed between the fingers, but floated on water, (apparently first stage of pneumonia.) The bronchial glands contained large deposits of calcareous matter. The pericardium contained an ounce of serum. The heart was normal. The mucous membrane of the small intestine was healthy; that of the colon and rectum thickened, softened, extensively ulcerated, and of very dark color, (almost gangrenous.) The liver was normal in size, but when examined under the microscope was found to be in a state of fatty degeneration. The cortical portion of both kidneys was very pale, and when examined microscopically was found to be fatty. The spleen was very small; weight about three ounces. The pancreas was normal; immediately adjoining it were several enlarged lymphatic glands, which were partially cretefied. Many of the mesenteric glands were in the same condition.—Acting Assistant Surgeon Thomas Bowen.

CASE 460.—Private Emmanuel Fox, company H, 48th Pennsylvania volunteers; age 20; admitted from City Point, Virginia, November 2, 1864. Chronic diarrhœa. [This man appears on the register of the depot hospital of the 9th Corps, admitted October 26th—acute rheumatism; and on that of the hospital steamer Ben Deford, admitted November 1st; sent to general hospital November 2d.] He was very weak, and had frequent copious liquid evacuations, which were generally preceded by pain and followed by exhaustion; the skin was unusually cool, the pulse irregular. Treatment: Tonics, stimulants, and warm applications to the abdomen; milk and extra diet. The patient's appetite was generally pretty good, but there was a craving for improper food. For some time the glands of the neck were swollen, and there was a thin discharge from the ears. The eyes also seemed to be affected, and for several days before death he complained of pains in the arms. For the last week he could be induced to take but little food. Died, December 5th. *Autopsy* twenty-seven hours after death: Rigor mortis disappearing; body extremely emaciated; very slight suggillation posteriorly. The cranial sinuses were filled with blood; the subarachnoid space contained an ounce of serum; the vessels of the pia mater were injected; the substance of the brain was normal. Neck and spinal column not examined. There were no pleuritic adhesions. The left lung was normal; the right lung was normal anteriorly, posteriorly several of the lobules in all the lobes were hepatized, some of them having advanced to the stage of gray hepatization. There were small calcareous deposits in several of the bronchial glands. The heart was very small, but otherwise normal. The liver was normal; the gall-bladder contained about an ounce and a half of bile. The spleen and pancreas were normal, as was also the mucous membrane of the stomach, duodenum, and jejunum. The mucous membrane of the ileum presented several patches of dark dirty-red color, but no ulcers could be detected. The mucous membrane of the colon and cæcum was thickened and inflamed in patches; it peeled off easily, and there were one or two spots in which it was abraded. The mucous membrane of the rectum also was very much inflamed, softened, and thickened, peeling off easily, but not ulcerated. The kidneys were pale, but otherwise normal.—Acting Assistant Surgeon Thomas Bowen.

CASE 461.—Private Oliver S. Barnum, company B, 26th Michigan volunteers; age 30; admitted from the depot hospital of the 2d Corps, City Point, Virginia, October 21, 1864. Chronic diarrhœa. Died, December 13th. *Autopsy* twenty-six hours after death: Rigor mortis great; body emaciated; slight suggillation posteriorly. Head, neck and spinal column not examined. There were no pleuritic adhesions. The posterior portions of both lungs were hypostatically congested. The pericardium contained about an ounce of serum. The heart was normal, except that the foramen ovale was imperfectly closed, two small openings connecting the cavities of the auricles; these openings were protected by valve-like processes of the inter-auricular septum; the right auricle and the vena cava were filled with dark blood. The liver was full of blood, but otherwise normal; the gall-bladder contained about half an ounce of bile. The spleen was enlarged, but normal in color and consistence; the pancreas darkly congested. The mesenteric glands were very much enlarged and dark colored, especially those connected with the lower part of the ileum. The mucous membrane of the stomach, duodenum, and jejunum was normal. Many of Peyer's patches in the lower three feet of the ileum were thickened and ulcerated; the surfaces of the ulcers presented a worm-eaten appearance. Some of the solitary glands in the ileum near the ileo-cæcal valve, in the cæcum, and in the first six inches of the ascending colon, were ulcerated, and many others were enlarged but not ulcerated. The mucous membrane of the colon and rectum seemed a little softened, but was otherwise normal. The kidneys were very large, and their vessels were full of blood. The bladder was full of urine.—Acting Assistant Surgeon Thomas Bowen.

CASE 462.—Private William H. Carey, company F, 28th Michigan volunteers; admitted from regimental hospital January 26, 1865. Chronic diarrhœa. Died, February 2d. *Autopsy* eighteen hours after death: Rigor mortis very great; body not emaciated, a well-developed muscular subject; slight suggillation posteriorly. The dura mater and pia mater were congested; the whole surface of the brain was coated with recent lymph deposited in the pia mater; the brain-substance was normal; the

lateral ventricles contained two drachms of serum. Neck and spinal column not examined. There were no pleuritic adhesions; the pleural sacs contained an ounce of serum. The upper lobe of the left lung was normal, the lower lobe hepatized; the middle lobe of the right lung was hepatized, the lower lobe congested. The pericardium contained half an ounce of serum. The heart and its valves were normal. The omentum was injected and somewhat thickened. Nothing abnormal was observed in either small or large intestine. The liver was very much enlarged and pale; it presented a mottled appearance when cut into; the gall-bladder contained two ounces of bile. The spleen was very much enlarged and softened. The pancreas and mesenteric glands were normal. The left kidney was normal, the right apparently softened; in its medullary portion were two small abscesses about the size of small peas; the bladder contained about six ounces of urine.

CASE 463.—Private George Roberts, company H, 59th Massachusetts volunteers; age 46; admitted from the depot hospital of the 9th Corps, City Point, Virginia, October 22, 1864. Chronic diarrhœa. Died, February 7, 1865. *Autopsy* seventeen hours after death: Rigor mortis very great; body greatly emaciated; slight suggillation posteriorly. Head, neck, and spinal column not examined. Both pleuræ were coated with recently deposited lymph. There were old adhesions of the lower lobe of the left lung, slight adhesions of the upper lobe of the right; extensive deposits of tubercle in the upper lobes of both lungs, and two large cavities in the upper lobe of the right; the middle and lower lobes of this lung were congested; there was also a small cavity in the lower lobe of the left lung. The bronchial glands were enlarged, black and softened. The pericardium contained an ounce of serum. The heart was normal. The omentum was congested. The liver was pale and flabby, apparently in a state of fatty degeneration; the gall-bladder contained half an ounce of bile. The spleen was normal in size, but softened. The mesenteric glands were enlarged and filled with softened tubercle. The mucous membrane of the small intestine was thickened and rough. [?] There were several small ulcers in Peyer's glands. The colon was normal. The kidneys were pale and soft; on examination with the microscope they were found to be in a state of fatty degeneration; the bladder contained six ounces of urine.

The next eighty-one cases are from the case-book of the THIRD DIVISION of the ALEXANDRIA HOSPITAL, Surgeon Edwin Bentley, U. S. V., in charge: *

CASE 464.—Corporal John Foster, company A, 49th New York volunteers; admitted September 10, 1862. Chronic diarrhœa. Died, October 25th. *Autopsy:* Body very much emaciated. The intestinal mucous membrane was extensively softened, particularly in the colon, where there was also some slight ulceration. The mesentery was highly congested.

CASE 465.—Private Archibald Toliver, company D, 20th Indiana volunteers; admitted October 14, 1862. Continued fever. Died, October 27th. *Autopsy* fifty hours after death: The mucous membrane of the stomach was softened, and presented numerous purple specks near the pyloric orifice. The spleen was enlarged and of light-blue color. The mucous membrane of the large intestine was soft and easily scraped off.

CASE 466.—Private John S. Nixon, company H, 59th New York volunteers; admitted October 29, 1862. Chronic diarrhœa. [The following entries with regard to this man appear on the register of the hospital of his regiment: December 25, 1861—diarrhœa; June 3, 1862—cold; June 17th—soreness in chest; June 26th—cough, and pain in the chest; June 27th—spitting blood; July 31st—night sweats; August 15th—sent to general hospital at Fortress Monroe.] The patient was admitted in a dying condition, having a loose stool every two hours. The discharges were dark, watery, bilious looking, and frequently involuntary. The pulse was scarcely perceptible at the wrist. Treatment: Stimulants, anodynes and astringents. Died, October 31st. *Autopsy* eight hours after death: Body extremely emaciated. The lungs were healthy. The pericardium contained four ounces of fluid. The gall-bladder was moderately filled with bile. The spleen was enlarged and softened. The intestines were distended with flatus, highly injected, and the mucous membrane softened. The bladder and kidneys were healthy.

CASE 467.—Private Aaron Case, company I, 5th Wisconsin volunteers; admitted October 24, 1862. Chronic diarrhœa, terminating in what was supposed to be typhoid fever. Died, November 1st. *Autopsy:* Body emaciated. The intestines were distended with flatus. The mucous membrane of the small intestine presented patches of softening and congestion, but no distinct ulceration could be found, nor was there any disease of Peyer's patches. The contents of the small intestine resembled pea-soup in color and consistence. Regions of injection were observed on the peritoneal surface of the small intestine, the mesentery and the greater omentum; the latter was connected to the abdominal parietes by adhesions which appeared to be recent. The liver was rather softer than normal. [No mention is made of the condition of the mucous membrane of the large intestine.]

CASE 468.—Private William H. Cole, company H, 11th Connecticut volunteers; age 23; admitted October 29, 1862. Chronic diarrhœa of two months' duration. The patient was extremely feeble and emaciated; he had daily from twelve to fifteen watery stools which were nearly natural in color, but occasionally streaked with blood. He had no cough, and a careful examination of the chest failed to detect anything abnormal. His abdomen was sunken, and somewhat tender on pressure; pulse frequent and feeble; tongue slightly coated with dry brown fur. A light but nutritious diet was ordered, and dry cups were applied to the abdomen, followed by warm poultices. Internally, alteratives, anodynes and astringents were tried, without benefit; subsequently turpentine emulsion and laudanum were administered, and a blister applied to the abdomen. Toward the close stimulants were freely given. Died, November 8th. *Autopsy:* The thoracic viscera were healthy. The mucous membrane of the small intestine was softened, and in three places ulcerated. The large intestine was much injected. The spleen slightly enlarged and quite firm. The liver and kidneys were normal.

* It is to be regretted that, in most instances, the records of this hospital do not show by whom the autopsies were made. It is known that many of them were made by Surgeon Bentley himself, or under his immediate supervision, but it is only possible to distinguish these from the others in a few cases.

CASE 469.—Private Peter Oleman, company A, 16th Michigan volunteers; admitted October 24, 1862. Chronic diarrhœa. Died, November 11th. *Autopsy:* Body extremely emaciated. There were slight pleuritic adhesions between the right lung and the thoracic parietes; firm adhesions to the diaphragm. The mucous membrane of the stomach was considerably injected and softened; that of the small intestine was also congested. In the large intestine the mucous membrane was congested, softened, and ulcerated, especially in the descending colon and rectum. There were tubercle-like deposits in the kidneys.

CASE 470.—Private James Ludlow, company F, 35th New York volunteers; admitted September 25, 1862. Chronic rheumatism and diarrhœa. He was extremely feeble, emaciated, and had large watery stools. Alteratives and astringents checked the diarrhœa for a time, but it recurred with increased violence; the tongue became dry; the pulse frequent and feeble. All treatment was obstinately resisted. Died, November 17th. *Autopsy:* Body extremely emaciated; abdomen sunken. The lungs were slightly congested. The heart normal. The mucous membrane of the ileum was softened, and in several places deeply ulcerated. The large intestine was not materially diseased. The liver and spleen were enlarged; the spleen was pulpy. The kidneys were normal.

CASE 471.—Corporal Louis Miller, company C, 7th New York volunteers; admitted October 24, 1862. Chronic diarrhœa. Died, November 20th. *Autopsy:* Body extremely emaciated. There was great discoloration, resembling ecchymosis, over the thorax and abdomen. The greater omentum and a large part of the mesentery were much injected. The mucous membrane of the jejunum and ileum was softened; in the ileum it was much injected. The mucous membrane of the colon was greatly injected and very much disorganized.

CASE 472.—Private Lewis Warner, company K, 118th Pennsylvania volunteers; admitted November 18, 1862. Dysentery. At the time of admission he had discharges from his bowels every three or four hours; the stools were very offensive, dark colored, grumous, and contained blood and pus; the pulse was small and rapid. Treatment: Acetate of lead and opium, stimulants. Died, November 20th. *Autopsy* eighteen hours after death: The bowels were distended with flatus. The external surface of the large intestine was of a dark lead-color; its mucous membrane highly congested, softened, and gangrenous in spots. The liver and spleen were healthy.

CASE 473.—Corporal John A. Schwartz, company G, 105th Pennsylvania volunteers; admitted October 14, 1862. Chronic diarrhœa. [This man appears on the regimental sick report as under treatment for diarrhœa May 29th, June 12th, and August 9th. [Died, November 20th. *Autopsy:* Body extremely emaciated. There was great discoloration, resembling ecchymosis, over the thorax and abdomen; excessive tympanites. The mucous membrane of the whole intestinal tract appeared to be inflamed and softened. The mesentery was much injected.

CASE 474.—Private Elias Havens, company E, 6th United States cavalry; admitted October 24, 1862. Chronic diarrhœa. Died, November 24th. *Autopsy:* The mucous membrane of the whole intestinal tract appeared to be inflamed; that of the stomach and small intestine was softened. The spleen was about twice its natural size.

CASE 475.—Private William Roland, company B, 1st Virginia cavalry; admitted November 2, 1862. Chronic diarrhœa of three months' duration. The patient was very feeble and much emaciated; skin dry; tongue red; abdomen flattened, and tender on pressure. Treatment: Alteratives, astringents and stimulants; warm fomentations to the abdomen. Died, November 28th. *Autopsy:* The omentum was congested; the mesenteric glands enlarged. The peritoneum of the small intestine was discolored, the mucous coat softened; there were several small ulcers near the ileo-cæcal valve. Liver and spleen slightly enlarged. The mesenteric glands were enlarged. [There is no record of the condition of the large intestine.]

CASE 476.—Private Joseph Tibbets, company B, 75th Ohio volunteers; admitted from regimental hospital, Chantilly, Virginia, November 18, 1862. Chronic diarrhœa of six weeks' duration. He was very feeble, much emaciated, and rapidly sank into a true typhoid condition, with dry tongue and delirium. Astringents, stimulants and concentrated food were given freely. Distressing nausea and vomiting supervened, utterly precluding for a time the administration of medicines by the mouth. A small blister applied over the epigastrium quieted the stomach somewhat, and the beef-essence and stimulants were resumed. Died, November 30th. *Autopsy:* The brain was normal. The lower lobes of the lungs slightly congested. The heart normal. The peritoneal coat of the lower portion of the small intestine was of a deep-red color; the mucous membrane of the ileum injected, softened, and in places entirely destroyed by ulceration. The mesenteric glands were greatly enlarged, and the greater omentum was much injected. The liver and spleen were slightly enlarged. The kidneys were normal.

CASE 477.—Private James F. Lynch, company H, 20th Massachusetts volunteers; age 30; admitted December 2, 1862. Chronic diarrhœa of eight weeks' duration. [This man appears on the sick report of his regiment as under treatment for diarrhœa from April 23d to April 27, 1862.] He was extremely emaciated, had large, liquid, and very frequent stools, which, during the last twenty-four hours of his life, were involuntary. Treatment: Astringents, opiates, stimulants and concentrated food. Died, December 7th. *Autopsy:* Body extremely emaciated; abdomen sunken. The thoracic viscera were normal. The mesentery was injected; the mesenteric glands enlarged. The mucous membrane of the small intestine was softened, particularly in the lower part of the ileum. The liver was somewhat enlarged and fatty. The spleen large and soft. [The condition of the large intestine is not recorded.]

CASE 478.—Private George H. Kline, company I, 23d Pennsylvania volunteers; admitted December 20, 1862. Chronic diarrhœa. Died, December 31st. *Autopsy:* Body greatly emaciated. There were extensive peritoneal adhesions; the omentum, the mesentery, and the peritoneal coat of the intestines much injected. The mucous membrane of the stomach and small intestine was injected and softened. [The condition of the large intestine is not recorded.]

CASE 479.—Private George A. Chamberlain, company A, 73d Ohio volunteers; admitted from the field hospital of the 11th Corps, Fairfax Court-House, Virginia, December 16, 1862. Chronic diarrhœa of long standing. He was extremely feeble

and much emaciated; had on an average ten stools daily, accompanied by pain in the bowels. The abdomen was tender on pressure; pulse frequent and feeble; tongue red and smooth. Stimulants and astringents were administered, and warm fomentations applied. Died, January 12, 1863. *Autopsy:* The lower lobes of both lungs were slightly congested. The heart was normal. The mucous membrane of the stomach was extremely pale; that of the ileum, especially in its lower part, was softened, and coated with a puruloid exudation. The colon was moderately congested. The mesenteric glands were much enlarged. The spleen enlarged. The liver enlarged and softened.

CASE 480.—Private John Fry, company G, 6th Maine volunteers; admitted December 20, 1862. Chronic diarrhœa. Died, January 17, 1863. *Autopsy:* The skin was unusually discolored; body greatly emaciated. The liver was small and lighter colored than usual; it was adherent to the diaphragm. The bloodvessels of the peritoneum covering the abdominal viscera were greatly injected. The colon exhibited signs of chronic inflammation. The mesenteric glands were enlarged and softened.

CASE 481.—Private J. H. Watkins, company E, 73d Ohio volunteers; admitted January 22, 1863. General debility. [This man appears on the register of the hospital of the 2d Division, 11th Corps, Fairfax Court-House, Virginia, admitted November 3, 1862—phthisis; no disposition recorded.] Died, February 2d, eleven days after admission. *Autopsy* eighteen hours after death: Body much emaciated. The heart was very small; the coronary vessels tortuous, like varicose veins. There were firm pleuritic adhesions on the left side; in other respects the thoracic viscera were healthy. The abdominal viscera also appeared to be healthy, except that there was some ulceration of the mucous membrane of the small intestine.

CASE 482.—Private John Wyatt, company B, 75th Ohio volunteers; admitted from the hospital of the 11th Corps, Fairfax Court-House, Virginia, January 22, 1863. Chronic diarrhœa of long standing. The patient was at first able to sit up and walk around a little, but soon grew feeble, and was confined to bed. He was somewhat emaciated. At the date of admission the discharges from the bowels were watery, more or less yellowish, and varied in frequency from half a dozen to a dozen in the twenty-four hours; they were attended with some little pain and tenesmus; there was more or less abdominal tenderness, and occasional colicky pains, which, however, were not severe; the stomach was irritable, and there was considerable nausea, especially after taking food, drink, or medicine; he had but little appetite for food, and complained of constant thirst; the pulse was small, frequent and feeble; the respiration unembarrassed. Treatment: Various astringents, especially acetate of lead, sulphate of copper, and tannic acid, were successively employed in combination with opium; occasionally a small dose of castor oil was administered; cod-liver oil in moderate doses was given as an analeptic; it was administered in peppermint-water, and was tolerated by the stomach better than any other medicine tried; rubefacients were applied to the abdomen. Milk, eggs, and farinaceous articles were mainly employed as food, and gum-water, toast-water, and tea for drink; but there seemed to be no power to assimilate nutriment, and the patient gradually sank, his intellect remaining clear to the last. Died, February 13th. *Autopsy* ninety hours after death: Body extremely emaciated. The thoracic viscera were normal. The stomach was healthy. There were patches of inflammation in the ileum, but no enlargement or ulceration of the glands of Peyer; there was a well-marked intussusception about an inch long in the lower part of the ileum. The omentum was atrophied, its bloodvessels injected. The mesenteric glands were enlarged. The liver was healthy. [There is no record of the condition of the large intestine.]

CASE 483.—Private Luke Lee, company E, 2d Maryland Cavalry; admitted February 12, 1863. Chronic diarrhœa of over two months' standing. The patient was much emaciated; had no appetite; great thirst; eight or ten painful passages daily. In the treatment astringents were chiefly relied upon, with Dover's powder or sulphate of morphia at night to induce sleep. Strict attention was paid to the diet, only farinaceous food being allowed. The patient improved gradually, and during the second week in March was allowed to have his clothes. He took cold March 16th. The diarrhœa recurred more severely than ever; he became very much prostrated, and died April 14th. *Autopsy* ten hours after death: The middle and lower lobes of the right lung were congested. There was great constriction and thickening of the coats of the large intestine in the vicinity of the sigmoid flexure, the lumen of the bowel being diminished to about one-fourth its natural diameter.

CASE 484.—Private Donald McIvor, company I, 15th Vermont volunteers; admitted April 14, 1863. Chronic diarrhœa. [This man appears on the hospital register of his regiment admitted March 25th—measles—sent to general hospital April 14th.] The patient was feeble and emaciated; he had from six to eight watery stools in the twenty-four hours; abdomen tender and painful; pulse frequent and feeble; tongue dry, red and smooth; no appetite. Treatment: Stimulants, alteratives, fomentations to the abdomen. Died, May 19th. *Autopsy:* Body greatly emaciated; abdomen sunken. The lungs were slightly congested. The heart normal. The peritoneum covering the intestines was discolored. The mucous membrane of the ileum was softened; that of the large intestine not materially altered. The liver and spleen were somewhat enlarged. The kidneys were healthy.

CASE 485.—Private J. E. Potts, company A, 137th New York volunteers; age 45; admitted June 17, 1863. Diarrhœa. [This man appears on the hospital register of his regiment, sent to general hospital June 16, 1863—fever and blistered feet.] The symptoms yielded readily to treatment. The patient improved in health, was able to eat his full ration, and was confined to bed but a portion of the time. June 27th: He complained of pain in the chest, accompanied by some dyspnœa; pulse not much accelerated. A blister was applied, and a combination of expectorants and anodynes directed. During the night he grew worse; his respiration became very laborious; he sank rapidly, and died June 28th, at 7 A. M. *Autopsy* twenty-four hours after death: Almost the whole of both lungs was congested. Nothing else abnormal was observed.

CASE 486.—Private David Keener, company F, 1st Pennsylvania cavalry; age 41; admitted June 28, 1863. Chronic diarrhœa of two months' duration. Died, July 12th. *Autopsy* eighteen hours after death: Great emaciation. The heart and lungs were healthy. The mucous membrane of both small and large intestine was inflamed and softened. There were a few ulcers in the colon. The liver and spleen were somewhat enlarged.

CASE 487.—Private John C. Fox, company F, 16th Pennsylvania cavalry; age 23; admitted June 28, 1863. Chronic diarrhœa of four months' duration. The patient was much emaciated; had the physical signs of a deposit of tubercle in the

left lung, and at the time of admission, from fifteen to twenty discharges from the bowels daily. He was placed upon an alterative and sustaining treatment, which slightly checked the diarrhœa. July 9th: He had an attack of hæmorrhage from the lungs, which was quite profuse at first, but lasted only a short time; and subsequently he continued to improve under treatment. August 15th: An almost total suppression of urine occurred. He was catheterized from time to time, but only a few drops of urine were obtained. This condition continued until death. Died, August 20th. *Autopsy* fourteen hours after death: There was an abundant deposit of softened tubercle in the left lung, a few scattered tubercles in the right; extensive pleuritic adhesions on the right side. The mucous membrane of both small and large intestine was inflamed, softened and ulcerated. The liver, spleen and kidneys appeared to be perfectly normal.

CASE 488.—Private A. Jerome Northrup, company G, 141st New York volunteers; admitted September 26, 1863. Chronic diarrhœa. The patient was much emaciated. The discharges from the bowels averaged ten daily; they were accompanied by great pain and tenesmus. He had a slight cough and a dull heavy pain in the lower part of the right lung, with the physical signs of pneumonia in the first stage. September 28th: Is somewhat better; there are now but four passages daily. October 2d: Copious diaphoresis, with cramps in the lower extremities. Died, October 4th. *Autopsy* ten hours after death: The lower lobe of the right lung was congested. The mucous membrane of the ileum was much inflamed; its solitary and agminated glands were enlarged. There was considerable thickening and contraction of the gut in the vicinity of the ileo-cæcal valve. The liver was much enlarged. [There is no record of the condition of the large intestine.]

CASE 489.—Private Joseph Berger, company I, 1st New York artillery; admitted September 26, 1863. Chronic diarrhœa of long standing. Has ten or twelve discharges per day; is much emaciated; suffers little pain. Treatment: Tonics, alteratives, opiates and astringents. Died, October 4th. *Autopsy* eight hours after death: The lungs were healthy. The spleen was congested. Throughout the whole intestinal tract more or less thickening was observed; the colon was contracted; the mucous membrane of the sigmoid flexure softened.

CASE 490.—Private William Evans, company E, 152d New York volunteers; admitted from regimental hospital October 17, 1863. Chronic diarrhœa of eight months' duration. The patient was extremely debilitated, and had a severe cough. Treatment: Tonics, alteratives, opiates, blisters to the abdomen. Died, November 2d. *Autopsy:* Body greatly emaciated. The lower lobe of the left lung was congested; the rest of the left lung and the whole of the right were healthy. Some thickening of the stomach was observed around the pyloric orifice. The mucous membrane of the ileum was softened, and near the ileo-cæcal valve it was ulcerated. The whole colon was very much contracted.

CASE 491.—Private Stephen Benson, company F, 7th Michigan cavalry; age 25; admitted July 19, 1863. Chronic diarrhœa. This patient presented every symptom of a confirmed lunatic, and it was stated by men of his regiment that he was idiotic when enlisted. He was very much debilitated; had suffered from diarrhœa for nearly five months; his pulse was 100 and feeble, and he labored under incontinence of urine. Treatment: Tonics and astringents; a blister over the abdomen. The diarrhœa was checked for a time, but dropsy made its appearance, and subsequently the flux returned in an aggravated form. Died, November 2d. *Autopsy* eight hours after death: The body was œdematous. There were slight pleuritic adhesions on the left side. The lungs were healthy. The heart was slightly enlarged. The liver was congested. The spleen was much enlarged and congested, weighing three pounds ten ounces. The lower portion of the ileum was thickened, but no ulcers were observed. [There is no record of the condition of the large intestine.]

CASE 492.—Private Henry L. Hewitt, company E, 154th New York volunteers; admitted September 27, 1863. Chronic diarrhœa. This patient was intemperate in his habits, and when admitted had some symptoms of delirium tremens. Died, November 8th. *Autopsy* sixteen hours after death: Body greatly emaciated. The stomach and intestines were anæmic; there was some thickening of the stomach about the pyloric orifice The mucous membrane of the ileum was softened, and its solitary follicles were enlarged. The sigmoid flexure of the colon was greatly contracted. No ulceration could be seen in any portion of the intestines.

CASE 493.—Private Adam Scott, company G, 143d New York volunteers; age 59; admitted September 26, 1863. Chronic diarrhœa of five months' duration. [This man appears on the hospital register of his regiment, sent to general hospital September 24th—typhoid fever.] The patient was greatly emaciated; his stomach very irritable; he had severe tenesmus, and passages from the bowels almost every half hour through the day and night. Treatment: Tonics, alteratives, astringents and opiates. Died, November 9th. *Autopsy* twenty hours after death: Body much emaciated; there were old pleuritic adhesions on both sides. An intussusception four inches long was found in the ileum. The whole length of the colon was contracted, its lumen being about half an inch in diameter. The liver was small.

CASE 494.—Private Amasa Whittemore, company B, 83d New York volunteers; age 32; admitted October 16, 1863. Chronic diarrhœa. This man was jaundiced, complained of pain in the right hypochondriac region, and of severe gastralgia. His urine was high colored. He had about eight loose stools daily. Treatment: Diaphoretics, alteratives and opiates. He passed into a typhoid condition, with small feeble pulse; his abdomen became tympanitic. For some time before death stimulants were freely administered. Died, November 13th. *Autopsy:* The lungs were congested. The ileum and colon were greatly contracted and thickened; there were three intussusceptions in the space of fourteen inches in the upper part of the ileum.

CASE 495.—Private Nelson Kinney, company G, 26th Michigan volunteers; age 27; admitted from regimental hospital October 17, 1863. Chronic diarrhœa. This patient was much emaciated, and had lost thirty pounds during three months. He had ten or twelve passages a day, accompanied by some tenesmus. Treatment: Astringents, alteratives and opiates. Died, November 15th. *Autopsy* fourteen hours after death: There was a deposit of miliary tubercles and an abundance of pigment in both lungs. The ileum and colon were greatly contracted but not ulcerated.

CASE 496.—Private Robert Alexander, company E, 149th Pennsylvania volunteers; age 18; admitted December 6, 1863. Typhoid fever. When admitted, this man was suffering from diarrhœa; his stomach was irritable; his urine scanty and high colored; his tongue red and dry. Treatment: Alteratives, turpentine, supporting diet. December 18th: There is more or less stupor, subsultus tendinum, involuntary stools. Died, December 21st. *Autopsy* nine hours after death: The lungs were healthy. The mucous membrane of the stomach was softened. The descending colon was thickened and softened, but no ulceration could be found. The liver was normal.

CASE 497.—Corporal David A. McClure, company I, 149th Pennsylvania volunteers; age 27; admitted December 7, 1863. Chronic diarrhœa. [This man appears on the register of the hospital of the 3d Division, 1st Corps, admitted April 20th—debility—returned to duty May 3d; admitted September 11th—diarrhœa—returned to duty September 17th; admitted November 3d—diarrhœa—returned to duty December 2d.] The patient was very much emaciated and debilitated by protracted diarrhœa; the discharges were watery and not accompanied by much pain. Treatment: Alteratives, tonics, astringents, opiates; extra diet. Died, January 1, 1864. *Autopsy* five hours after death: Body greatly emaciated. The lungs were comparatively healthy. The mucous membrane of the whole small intestine was thickened. The colon was very little thickened.

CASE 498.—Private Solomon Leasure, company I, 149th Pennsylvania volunteers; admitted December 6, 1863. Chronic diarrhœa. Died, January 29, 1864. *Autopsy* thirty hours after death: Great emaciation. The heart and lungs were perfectly healthy; there were no pleuritic adhesions. The ileum was contracted in several places, the colon throughout almost its whole extent; the coats of the colon were thickened and indurated. The liver and spleen were healthy; the mesenteric glands enlarged. The kidneys were somewhat firmer than natural.

CASE 499.—Private James Ainsworth, company I, 5th Pennsylvania reserves; age 19; admitted from regimental hospital February 12, 1864. Acute dysentery. [This man appears on the hospital register of his regiment, sent to hospital February 12—dysentery.] Pneumonia of an asthenic type supervened almost immediately after his admission. Treatment: Dover's powder, dry cups to the chest, milk-punch. The dysenteric symptoms subsided, and there were no discharges from the bowels for several days before death. Died, February 23d. *Autopsy* eighteen hours after death: The lower lobe of the right lung was in the stage of gray hepatization, the other lobes in the stage of red hepatization; the left lung was congested. The intestines presented no evidences of serious disease.

CASE 500.—Private David B. Jones, company H, 148th Pennsylvania volunteers; age 29; admitted from regimental hospital March 24, 1864. Chronic diarrhœa. The patient, who was of a scrofulous constitution, had suffered from diarrhœa for four months, and was much exhausted. A dose of castor oil and laudanum was administered immediately after he entered hospital; subsequently he took pills of tannic acid and opium. Under this treatment the number of stools was speedily reduced to one daily; nevertheless he rapidly sank, and died comatose, March 30th. *Autopsy:* Both lungs contained tubercles, which were especially abundant in the upper lobe of the right lung; this lobe was also the seat of an abscess containing about an ounce of fluid. The stomach and small intestine were healthy. The mucous membrane of the colon was thickened, softened, and ulcerated. The spleen contained numerous tubercles.—Surgeon E. Bentley, U. S. V. [Nos. 296 to 298, Medical Section, Army Medical Museum, are from this case. No. 296 is a portion of the ascending colon near the cæcum; No. 297 a portion of the right extremity of the transverse colon; in both the mucous membrane is considerably thickened, and presents follicular ulcers, which are most numerous in No. 296. No. 298 is the spleen, with a number of small tubercles just beneath its peritoneum.]

CASE 501.—Private Henry Nunemaker, company D, 187th Pennsylvania volunteers; age 19; admitted from City Point, Virginia, July 2, 1864. Typhoid fever. Died, July 15th, at 6.30 P. M. *Autopsy* fifteen hours and a half after death: Body very much emaciated. The heart, lungs, liver and spleen were normal. There was extensive inflammation of the stomach and the whole intestinal canal, with numerous large and indurated ulcers in the ileum, cæcum, colon and rectum.

CASE 502.—Private Charles W. Akley, 7th Maine battery; age 16; admitted July 4, 1864. Chronic diarrhœa. This patient had been ill five weeks, and was so much debilitated as to be unable to walk. His appetite was poor, and he had much thirst; tongue whitish; pulse 90 to 100. He had ten or eleven stools daily, accompanied by griping pain in the abdomen, and tenesmus. Gave a dose of castor oil followed by chalk-mixture and laudanum. July 6th: Has seven stools daily, but no longer complains of abdominal pain. To have a nutritious diet and stimulants in small quantities. July 12th: Appetite poor. Prescribed a mixture containing aromatic sulphuric acid and laudanum. Died, July 17th, at 3 P. M. *Autopsy* eighteen hours after death: Body much emaciated. Many large ulcers were found in the ileum, cæcum, and colon. The other organs were healthy.—Surgeon E. Bentley, U. S. V. [Nos. 422 and 423, Medical Section, Army Medical Museum, are from this case. No. 422 is a portion of the transverse colon, which presents a number of large irregular ulcers such as are observed in diphtheritic dysentery after the separation of the sloughs; the muscular coat is exposed at the bottom of the ulcers. No. 423 is a portion of the descending colon with similar ulcers, some of which, however, penetrate to the peritoneum, while from the edges of some the mucous membrane hangs in shreds.]

CASE 503.—Private Nathaniel Rowe, company G, 44th New York volunteers; age 50; admitted from the hospital of the 1st Division, 5th Corps, City Point, Virginia, July 2, 1864. Chronic diarrhœa. Died, July 23d, at 1 P. M. *Autopsy* twenty-two hours after death: Body much emaciated. There was extensive pleuro-pneumonia on the right side. The liver was large and congested. The mucous membrane of the colon was inflamed.

CASE 504.—Private Joseph Wilkins, company C, 97th New York volunteers; age 23; admitted July 2, 1864. Chronic diarrhœa. [This man appears on the hospital register of his regiment, admitted December 9, 1863—diarrhœa—returned to duty December 16th; admitted March 24, 1864—chronic diarrhœa—returned to duty April 8th; admitted April 14th—diarrhœa—

returned to duty April 16th; admitted April 25th—diarrhœa—returned to duty April 28th; admitted June 10th—diarrhœa—sent to division hospital June 11th. He appears on the register of the hospital of the 3d Division, 5th Corps, admitted June 12th—diarrhœa—sent to corps hospital June 21st. He is borne on the register of the depot hospital of the 5th Corps, City Point, Virginia, admitted June 24th—sent to general hospital July 1st.] Died, July 23d. *Autopsy* six hours after death: Both lungs were extensively inflamed; the pleural sacs contained about half a pint of fluid. The heart and liver were normal; the gall-bladder was distended with bile. The mucous membrane of the large intestine was extensively inflamed and ulcerated.

CASE 505.—Corporal William Powell, company K, 16th New York cavalry; age 43; admitted from Falls Church, Virginia, July 13, 1864. Chronic diarrhœa. In this case the symptoms so closely resembled those of typhoid fever in its advanced stages that the disease was so registered. Died, July 24th, at 4 A. M. *Autopsy* six hours and a half after death: Body greatly emaciated. The lower lobe of the right lung was hepatized, and attached by slight pleuritic adhesions to the thoracic parietes. The liver was large and fatty. The spleen much enlarged and full of blood. Two intussusceptions were found in the ileum. There were many large ulcers in the lower two feet of the ileum, and in the large intestine from the ileo-cæcal valve to the anus.—Surgeon E. Bentley, U. S. V. [No. 419, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the colon, presenting numerous follicular ulcers, many of which are circular in form, with the diseased follicle remaining in the centre of the ulcer.]

CASE 506.—Private William Cousins, company I, 31st Maine volunteers; admitted July 6, 1864. Chronic diarrhœa. Died, August 1st. *Autopsy* six hours after death: There was extensive ulceration of the ileum, cæcum, colon and rectum, with a general inflammatory condition of the whole intestinal canal and thickening of the mucous membrane.

CASE 507.—Private Smith Ward, company A, 149th Pennsylvania volunteers; age 16; admitted July 3, 1864. Acute diarrhœa. Died, August 1st. *Autopsy* twenty-three hours after death: Body slender and emaciated. There was inflammation of the right lung and pleura. The ileum, cæcum and colon were inflamed and ulcerated.

CASE 508.—Quartermaster Sergeant Hans C. Frederickson, 3d Veteran Reserve Corps; age 24; admitted from regimental quarters July 22, 1864. Acute dysentery. At the time of admission the patient was suffering from frequent hæmorrhagic discharges from the bowels, with tenesmus, accompanied by very severe pains in the lower part of the abdomen. He had been sick two or three weeks, but the symptoms had only recently become severe. About two months previously his horse had thrown him, and in falling had injured him in the right iliac region with the pommel of the saddle. He stated that he vomited a large quantity of blood at the time of the accident, and had not entirely recovered from the effects of the injury, when he was attacked with diarrhœa which soon became dysenteric in character. He was at first treated with quinine, as there seemed to be periodical exacerbations of the symptoms; diaphoretics were also administered, and enemata of starch-water and laudanum. He improved for a few days, after which the symptoms again became more severe. Alteratives, astringents and stimulants were used without effect. He remained perfectly conscious till a very short time before his death. During the twenty-four hours immediately preceding dissolution the evacuations were almost pure blood, and he presented all the appearances of one suffering from exhausting hæmorrhage. Died, August 4th. *Autopsy* twenty-four hours after death: Body considerably emaciated. The stomach was inflamed. The mucous membrane of the colon and rectum presented a number of large deep ulcers, some of which extended to the peritoneal coat. The cæcum adhered to the walls of the abdomen for a space the size of a silver dollar. The other organs appeared to be healthy.

CASE 509.—Private William Down, company F, 187th Pennsylvania volunteers; admitted August 1, 1864. Chronic diarrhœa. [This man appears on the register of the Augur hospital, near Alexandria, Virginia, admitted July 28th—remittent fever—sent to general hospital August 1st.] Died, August 8th. *Autopsy* sixteen hours after death: Body greatly emaciated. There was extensive inflammation of the left lung and pleura. The pericardium was firmly adherent to the heart at every point, and there was some disease of the auriculo-ventricular valves. The lower portion of the ileum, the cæcum, and the colon were ulcerated, and there was much thickening of the mucous membrane.

CASE 510.—Edward Phipps, bugler, company K, 2d Massachusetts cavalry; admitted from the Provost Marshal, July 26, 1864. Typhoid fever. Died, August 9th. *Autopsy* twelve hours after death: Body much emaciated. An extensive deposit of tubercle was found in the right lung, and there was considerable inflammation of the lung and pleura. The other organs of the chest were healthy. Marked ulceration of lower portion of ileum, cæcum, and colon was observed. The other abdominal organs were healthy.

CASE 511.—Private Harrison Aber, company B, 14th New York artillery; admitted from Soldiers' Rest May 8, 1864. Remittent fever. Died, August 9th, of chronic diarrhœa. *Autopsy* fourteen hours after death: Body somewhat emaciated. The liver and spleen were engorged. The ileum, colon and rectum were ulcerated.

CASE 512.—Private Eli Merrill, company E, 58th Massachusetts volunteers; admitted from the army of the Potomac June 15, 1864. Acute diarrhœa. Died, August 9th. *Autopsy* eighteen hours after death: Body considerably emaciated. The mucous membrane of the stomach and of the whole intestinal canal was inflamed. The heart was very small. The mucous membrane of the bladder was much congested. The other organs were healthy.

CASE 513.—Corporal George Martin, company B, 110th Ohio volunteers; admitted August 10, 1864. Typhoid fever. [This man appears on the register of the depot hospital of the 6th Corps, admitted July 6, 1864—diarrhœa; no disposition.] The patient was insensible at the time of admission, and died next day. *Autopsy* twenty hours after death: Body much emaciated. There was extensive ulceration of the ileum, cæcum and colon, and considerable thickening of the mucous membrane.

CASE 514.—Private A. P. Knox, 8th company, New York sharpshooters; admitted July 2, 1864. Acute diarrhœa. [This man appears on the register of the hospital of the 4th Division, 5th Corps, admitted June 21st—acute diarrhœa—sent to

depot hospital June 24th. His name is borne on the register of the depot hospital of the 5th Corps, City Point, Virginia, sent to general hospital July 21st.] Died, August 13th. *Autopsy* four hours after death: Body much emaciated. There was extensive inflammation of the rectum, and ulceration of the cæcum and colon. The other organs were normal.

CASE 515.—Private Jared Seymour, company D, 19th New York cavalry; age 29; admitted from Prince street prison August 15, 1864. Chronic diarrhœa and insanity. [This man appears on the register of Lincoln hospital, Washington, D. C., admitted March 25, 1864—insanity—deserted April 1st.] The patient was exceedingly emaciated, passed his stools and urine involuntarily, and was much deranged in mind. It was found necessary to watch him constantly to prevent him from swallowing the medicine prescribed for others, which he would do regardless of taste or consequences. Alteratives, astringents and stimulants were tried without beneficial effect. Died, August 27th. *Autopsy:* Brain not examined. The lungs were healthy. No inflammation of the mucous membrane of the small or large intestine was detected. The liver and spleen were soft and dark colored, breaking down readily under pressure.

CASE 516.—Private James Carroll, company K, 84th New York volunteers; age 55; admitted August 8, 1864. Acute diarrhœa. Died, September 2d. *Autopsy* two hours and a half after death: No rigor mortis; no stasis; body much emaciated. There was some effusion of serum beneath the arachnoid; the brain-substance was normal, or a trifle harder than usual; the lateral ventricles contained three or four drachms of serum; the middle commissure of the brain was absent. There was an abscess in the left parotid gland. The lungs were of a gray color mottled with black, and were adherent on both sides by firm bands to the thoracic parietes and the diaphragm. The heart was normal; its right ventricle contained a mixed clot, both auricles yellow clots. The liver was small, pale, and rather free from blood. The spleen two inches and a half long by an inch and a half wide. The kidneys were normal. The transverse colon, descending colon and rectum were of a dark-red color, and presented numerous ulcers. The ileum was not inflamed. The mesenteric glands not enlarged.

CASE 517.—Private Morris Biederman, company I, 39th New York volunteers; admitted August 11, 1864. Acute diarrhœa. [This man appears on the register of the hospital of the 1st Division, 2d Corps, admitted July 24th—intermittent fever; no disposition; and on the register of the depot hospital of the 2d Corps, admitted July 27th—convalescent; no disposition.] Died, September 5th, at 7 A. M. *Autopsy* four hours after death: Body very much emaciated. The lower lobe of the left lung was hepatized, the left bronchial tubes inflamed; the right lung was healthy. The heart was normal. The liver of the ordinary size. The spleen small. The ileum was inflamed, with slightly enlarged solitary glands. The colon was similarly affected and inflamed, especially at the caput coli; it contained some fluid fæces.

CASE 518.—Private Robert B. Craig, company M, 2d New York heavy artillery; age 26; admitted August 11, 1864. Typho-malarial fever. He had previously suffered from chronic diarrhœa. At the time of admission he had some fifteen fetid watery stools daily, and there was excessive tenderness in the right iliac region; he was emaciated and debilitated; pulse 93 and feeble. As he seemed quite feverish, solution of acetate of ammonia was prescribed, combined with tincture of aconite; for the diarrhœa a turpentine mixture, and subsequently Hope's camphor mixture; stimulants were also administered. The diarrhœa was readily controlled, the febrile symptoms abated, and his condition seemed favorable, when a severe cough set in accompanied by excessive expectoration. Expectorants, tonics and stimulants were employed, and counter-irritants applied to the chest, but without benefit. Died, September 5th. *Autopsy* seven hours after death: There were tubercles in both lungs, and numerous purulent spots about the size of a cherry; the right middle lobe was the only one not affected. The heart was normal. The sigmoid flexure and descending colon were inflamed, and presented spots of ulceration the size of peas. The mucous membrane of the ileum was somewhat inflamed. The other abdominal viscera were normal.

CASE 519.—Private Emmanuel Straw, company I, 58th Pennsylvania volunteers; age 50; admitted from Prince street prison September 24, 1864. Chronic diarrhœa. This case was complicated with hemorrhoids and great irritability of the stomach. An unusual degree of jactitation was noticed during the last week of his life. Died comatose, October 20th. *Autopsy* eight hours after death: There was an excess of black pigment on the surfaces of the lungs, which were otherwise healthy; the lower lobe of the right lung was adherent to the thoracic parietes. The mucous membrane of the small intestine was inflamed throughout its whole length. The colon was extensively ulcerated. The liver was unusually large, and presented the nutmeg appearance. The kidneys were fatty.

CASE 520.—Private Eliphalet Phillips, company M, 10th New York cavalry; age 18; admitted August 15, 1864. Chronic diarrhœa. [This man appears on the register of the hospital of the Cavalry Corps, army of the Potomac, admitted July 31st—diarrhœa—sent to general hospital August 9th.] He had been sick about three months. At the time of admission the average number of stools was about five daily, and he was very much emaciated. About the first of October the patient was attacked with bronchitis, for which diaphoretics and expectorants were administered with benefit, but a slight cough remained. Died, November 1st, at 5 P. M. During the progress of this case astringents, tonics, ipecacuanha and opium were used in various combinations in connection with nutrients and stimulants. *Autopsy* fifteen hours after death: Body very rigid and much emaciated. The pericardium contained two ounces of light-colored serum. The heart was normal. The lungs were small; the left lung was highly congested; the upper lobe of the right lung contained many softened tubercles. The bronchial tubes were filled with pinkish frothy mucus. The stomach contained about four ounces of partly digested food. The mucous membrane of the small intestine was highly congested, in some parts inflamed; the last eight inches above the ileo-cæcal valve presented some patches of ulceration. The colon was highly congested, inflamed in some parts, with indications of incipient ulceration. The mesenteric glands were tuberculous. The liver was large, pale outside, mottled inside; the gall-bladder contained half an ounce of yellow inspissated bile. The spleen, pancreas and kidneys were normal. The bladder was empty.

CASE 521.—Private Francis M. Fox, company K, 109th New York volunteers; age 23; admitted from Augur hospital July 20, 1864. Consumption. [This man appears on the register of the Mount Pleasant hospital, Washington, D. C., admitted June 21st—contusion of lumbar region by falling from a tree; returned to duty June 22d. He appears on the register of the

Augur hospital, near Alexandria, Virginia, admitted July 4th—chronic rheumatism—sent to general hospital July 20th.] The patient was suffering from an exhausting diarrhœa and was much emaciated; his cough was not severe. There was dulness on percussion over the whole of the right lung. Treatment: Astringents, expectorants, cod-liver oil, stimulants and a nutritious diet. The diarrhœa was readily controlled, but the chest-symptoms were persistent. Died, November 13th. *Autopsy* eighteen hours after death: Body moderately rigid and much emaciated; several nævi materni were observed on the right hip. The right lung was infiltrated with miliary tubercles, and had several cavities in its upper lobe; the left lung was also tuberculous, but less diseased than the right; its upper lobe was adherent to the parietes of the chest. The mucous membrane of the trachea was ulcerated. The heart was small but normal; there was a small clot in the left ventricle; the large veins and arteries were nearly empty. The liver was enlarged; the gall-bladder empty. The spleen enlarged and filled with black blood. The mesenteric glands were cheesy. The small intestine was ulcerated in several places, in others presented distinct pustules; [?] three distinct intussusceptions of the small intestine were observed. The large intestine was congested and presented a number of ulcers. The kidneys were enlarged; the urinary bladder contained eight ounces of light-colored urine.

Case 522.—Recruit George Wayne, 79th New York volunteers; age 18; admitted September 9, 1864. Acute diarrhœa. [This man appears on the register of the Augur hospital, near Alexandria, Virginia, admitted September 5th—remittent fever—sent to general hospital September 9th.] Treatment: Hope's camphor mixture, milk-punch, &c. The diarrhœa was speedily brought under control, but several relapses took place, and the patient remained weak. November 20th: Typhoid symptoms set in, and a turpentine mixture was prescribed. November 23d: He was attacked by diphtheria, and died November 29th. In the treatment of this last complication milk-punch was given freely, and the throat swabbed alternately with solution of chlorate of potassa and dilute acetic acid. A large quantity of pseudomembrane was thus removed. *Autopsy* thirteen hours after death: The pharynx, larynx, trachea, and bronchial tubes were inflamed, and presented ulcerated patches. The upper lobes of both lungs were pneumonic. The liver and spleen were much enlarged and softened, the latter being very soft; the gall-bladder was distended with bile. There was extensive inflammation and ulceration of the mucous membrane of the bowels. In the cæcum several cicatrices of former ulcers were observed.

Case 523.—Sergeant William F. Tousley, company K, 6th Ohio cavalry; age 27; admitted from City Point, Virginia, November 30, 1864. Diarrhœa. [This man appears on the register of the hospital of the 2d Division of the Cavalry Corps of the army of the Potomac, admitted November 2d—remittent fever—sent to depot hospital November 20th. He is borne on the register of the depot hospital of the Cavalry Corps, City Point, Virginia, admitted November 20th—diarrhœa—sent to general hospital November 29th.] Was much emaciated and exhausted; complained of pain in the bowels; had suffered from diarrhœa for several weeks before admission. Three blue-mass pills were given, followed by castor oil; afterward opiates, stimulants and astringents. He continued to have on an average five or six stools daily, and gradually failed. The last week of his illness he had but two or three evacuations daily. Died, December 6th. *Autopsy* twelve hours after death: There was some engorgement of the posterior portion of both lungs. The pericardium was adherent to the heart. The liver presented the nutmeg appearance. The spleen was very small. The mucous membrane of the intestines was considerably injected; this was most marked in the large intestine. In the descending colon, sigmoid flexure, and rectum the mucous membrane was ulcerated.

Case 524.—Private Michael Clancey, 102d company, 2d battalion, Veteran Reserve Corps; age 26; admitted May 25, 1864. Diarrhœa. Had been sick three weeks. This man was wounded in the left arm at Malvern Hill, July 1, 1862, in consequence of which he suffered amputation of the humerus at the junction of the middle and upper thirds August 15th. He was subsequently transferred to the Veteran Reserve Corps. The first notes of the case were taken August 25, 1864. He had then from eight to twelve feculent stools daily, with some nausea and griping. Alteratives and astringents were prescribed. A few weeks later he complained of cough and pain in the upper part of his chest. On percussion, considerable dulness was observed below the left clavicle and extending over the upper portion of the left lung; over the same region rude respiration and a slight mucous rale were heard. His diarrhœa now averaged from five to six passages daily. Cod-liver oil and syrup of iodide of iron were added to the former remedies, but without permanent benefit. He began to emaciate, became very low-spirited, lost his appetite, and soon took to his bed. Finally the stools became involuntary, and he died December 13th. Some two weeks before death an abscess formed near the anus and discharged a thick dark-colored pus. *Autopsy* twenty-four hours after death: The body was greatly emaciated. The pericardium was filled with serum mixed with lymph. Both lungs contained tubercles and vomicæ, the upper part of the left lung being most extensively diseased. The spleen was normal; the liver and kidneys fatty; the mesenteric glands enlarged. There was tubercular ulceration of the ileum. The mucous membrane of the colon was thickened and presented numerous ulcers. The vermiform appendix was adherent to the upper part of the rectum, and the cavities of the two communicated through an ulceration. On the left side of the anus was an incomplete fistula leading to an abscess cavity the size of a walnut.—Acting Assistant Surgeon W. C. Minor. [Nos. 463 and 464, Medical Section, Army Medical Museum, are from this case. No. 463 is from the upper portion of the ileum, and presents near its centre a group of small irregular ulcers, opposite which, on the peritoneal surface, there are a number of minute tubercles. No. 464 is the lower part of the rectum, with a portion of the skin surrounding the anus; the mucous membrane is thickened, and presents numerous small follicular ulcers; at the margin of the anus there are two small fistulous orifices communicating with an abscess-cavity rather larger than a walnut, situated in the areolar tissue just outside the sphincter ani.]

Case 525.—Private Calvin Clements, company C, 5th Pennsylvania heavy artillery; age 19; admitted October 10, 1864. Chronic diarrhœa. He so far recovered as to be able to do the duties of an orderly in the office of the hospital. About the first of November he was attacked by fever, accompanied by cough, and pain in the right lung. This was treated by a combination of alteratives, expectorants and opium, and a blister was applied to the chest. The fever assumed a low character, and sordes accumulated on the teeth and lips. A number of small superficial abscesses made their appearance on the chest and abdomen. Twenty-five or thirty of these were opened and discharged a thick white pus, after which convalescence set in, and he got well enough to be about the ward. About December 10th he was seized with sudden congestion of the lungs, the symptoms being

difficulty in breathing, dry hoarse cough, pain across the upper portion of the chest and over most of the right lung. Stimulating expectorants and alteratives were administered, and counter-irritants applied, without benefit. Died, December 24th, at 5 P. M. *Autopsy:* Body emaciated; mark of a blister on the right side. The brain was normal, except that the middle commissure was absent; some effusion was observed beneath the arachnoid over the cerebral hemispheres. Firm white clots were found in both sides of the heart. The posterior part of the cricoid cartilage was necrosed and surrounded by a collection of pus; this abscess had no apparent opening. The bronchial glands on the right side were greatly enlarged, and one of them, at the root of the right lung, contained pus and calcareous matter. The lower lobe of the right lung was infiltrated with miliary tubercles; the intervening lung-tissue was in the early stage of pneumonia, and its posterior surface coated with a little coagulable lymph; the rest of the right lung and the whole of the left lung appeared to be free from disease. The liver was large and pale. The spleen was small, and showed on section numerous white spots, supposed to be enlarged Malpighian bodies, but was otherwise of normal appearance. The mesenteric glands were enlarged. The ileum was slightly injected, and there were pigmentary deposits in the colon. The kidneys small, quite granular, their cortical substance yellow.—Acting Assistant Surgeon W. C. Miner. [No. 467, Medical Section, Army Medical Museum, is from this case. The specimen consists of the larynx and trachea with the enlarged bronchial glands attached; the air passages are laid open posteriorly, the section passing through an abscess surrounding the cricoid cartilage, which is necrosed and lies free in the abscess-cavity.]

CASE 526.—Private Elias Markle, company E, 184th Pennsylvania volunteers; age 34; admitted from City Point, Virginia, November 30, 1864. [This man appears on the register of the field hospital of the 2d Division, 2d Corps, admitted November 15th—dropsy; no disposition; and on the register of the depot hospital of the 2d Corps, City Point, Virginia, admitted November 26th—diarrhœa—sent to general hospital November 29th, per steamer State of Maine.] The patient was considerably emaciated, and much exhausted by the journey. He had little or no appetite, and complained of frequent bloody stools accompanied by abdominal pain and tenesmus. ℞. Oil of turpentine, tincture of opium and castor oil, each one drachm, powdered gum Arabic two drachms, water five ounces. Take a tablespoonful every three hours. This relieved the tenesmus, and the blood disappeared from the stools. During the first half of December he appeared to be improving; his bowels, however, remained loose, his stomach became irritable, he complained of soreness and dryness of the pharynx; a low form of bronchitis supervened, the skin became harsh and dry, and at times the extremities were œdematous. Brandy-punch and beef-essence were freely administered, as well as opiates and astringents, but without benefit. There was no cerebral difficulty at any time. He gradually failed, and died December 30th, at 2 A. M. *Autopsy* eight hours after death: There was some engorgement of the posterior part of the lungs, and some bronchial inflammation. The heart was fatty. The liver presented the nutmeg appearance. The kidneys were small and fatty. The colon was ulcerated, particularly in the neighborhood of the ileo-cæcal valve.

CASE 527.—Private Adam Schaffer, company G, 84th Pennsylvania volunteers; age 46; admitted from City Point, Virginia, November 30, 1864. Chronic diarrhœa. [This man appears on the register of the depot hospital of the 2d Corps, City Point, Virginia, admitted November 18th—acute diarrhœa—sent to general hospital November 29th, per steamer State of Maine.] Treated with astringents, tonics, anodynes and stimulants. Died, January 3, 1865. *Autopsy* eighteen hours after death: Moderate rigor mortis. The thoracic cavity contained a small quantity of bloody serum. There were firm pleuritic adhesions on the right side. The lower lobe of the right lung was hepatized. About eight ounces of serum were found in the abdominal cavity. The liver was brownish on section, and exuded a good deal of bloody serosity. The spleen was of medium size and purplish. The mucous membrane of the jejunum and ileum was inflamed and softened in patches; the solitary glands were enlarged and ulcerated. The cæcum and rectum were ulcerated in spots. The hemorrhoidal veins were enlarged.

CASE 528.—Private William Johnson, company C, 48th Pennsylvania volunteers; admitted October 21, 1864. Chronic diarrhœa. [This man appears on the register of the depot hospital of the 9th Corps, City Point, Virginia, admitted October 1st—debility—sent to general hospital October 20th, per hospital transport Ben Deford.] The patient was very feeble, and had copious frequent stools, the discharges being thin and clay-colored. Blue mass combined with opium was given for a time, followed by mineral and vegetable astringents combined with opium, and, as the patient became weaker, gentle tonics and stimulants. Opiate and astringent enemata were frequently given to relieve the pain and tenesmus. His appetite gradually failed; he grew steadily weaker, and died February 8, 1865. *Autopsy* eighteen hours after death: Slight suggillation posteriorly; rigor mortis moderate. There were pleuritic adhesions on the left side. Both lungs were congested, and a bloody serosity exuded on section. The bronchial glands were enlarged. The stomach was normal. The mucous membrane of the jejunum presented patches of ulceration. The ileum was ulcerated as far as the ileo-cæcal valve. In the colon there were patches of bluish ulceration and discolorations, supposed to be cicatrices. The spleen was small. The kidneys were small but normal.

CASE 529.—Private David Shawley, company A, 45th Pennsylvania volunteers; age 18; admitted July 20, 1864. Chronic diarrhœa. [This man appears on the register of the Augur hospital, near Alexandria, Virginia, admitted July 4th—chronic diarrhœa—sent to general hospital July 20th.] Improved under treatment, and was on duty as a cook February 1, 1865, when he was attacked by pneumonia, and died February 18th. *Autopsy:* No rigor mortis; body still warm. There was considerable effusion in the ventricles of the brain. Both lungs contained miliary tubercles, and presented evidences of intercurrent pneumonia, which at the apices had advanced to gray hepatization; the left lung was coated with layers of whitish-yellow lymph half an inch thick, by which it was extensively connected with the thoracic parietes; there was very little serum in the pleural sac; at the apex of the right lung was a vomica the size of a pea. The heart was normal. The liver presented the nutmeg appearance. The spleen was large, of a dark-brown color, and softened. In the ileum an intussusception some three inches in length was observed, and the mucous membrane presented a number of tubercular ulcers. The corresponding mesenteric glands were as large as marbles, and contained a cheesy tubercular deposit; there were, however, no tubercles on the intestinal peritoneum.

CASE 530.—Private Jerome Benson, company C, 123d Indiana volunteers; age 18; admitted from Soldiers' Rest February 18, 1865. Diarrhœa and pleurisy. This patient had a severe diarrhœa, cough, and bloody expectoration, with pain in the chest, increased on inspiration; his skin was hot; the pulse quick. The diarrhœa diminished under astringent treatment, but the chest-symptoms became more severe, and sordes collected on the teeth and lips. February 22d: Ordered a combination of ipecacuanha with mercury and chalk. February 23d: The dyspnœa has become intense. Ordered stimulants. Died, February 23d. *Autopsy* sixteen hours after death: Body well nourished; decided rigor mortis; the marks of a blister on the right side of the chest; suggillation posteriorly. There were recent pleuritic adhesions on the left side, but no effusion in the pleural sac. In the upper lobe of the left lung there was a deposit of tubercle. The pericardium contained four ounces of light-colored serum. The heart was small but normal. The stomach was large and filled with gas; near the pyloric orifice its mucous membrane was inflamed and ulcerated. The small intestine presented a number of tubercular ulcers. The appendix vermiformis was doubled upon itself, and bound in that position by bands of lymph. The left kidney contained tubercles. The other viscera appeared to be normal.

CASE 531.—Corporal James J. Vansant, company G, 180th Ohio volunteers; age 18; admitted from Soldiers' Rest February 22, 1865. Chronic diarrhœa. Was treated with astringents and stimulants. February 25th: He was attacked with symptoms of pneumonia—cough, sanguineous expectoration, hot skin, &c. Prescribed quinine. February 28th: The symptoms assumed a typhoid character, and low muttering delirium set in. Died, March 2d. *Autopsy* seven hours after death: Body muscular and well nourished; great rigor mortis, especially in the lower limbs. There were firm pleuritic adhesions on the right side. The lower lobe of the left lung was much congested, and exuded a large quantity of bloody serosity on section. The pericardium contained four ounces of light-colored serum. The heart was normal. The spleen was soft, congested, and weighed twenty-two ounces. The liver was large and of the nutmeg character; the gall-bladder full of yellow bile. The stomach was inflamed in spots, and contained four ounces of greenish bilious matter. Peyer's glands were inflamed, and very many of them ulcerated. The large intestine was congested and inflamed. The kidneys were small and granular.

CASE 532.—Private John Powell, company G, 26th Kentucky volunteers; admitted from Soldiers' Rest February 11, 1865. Chronic diarrhœa. The diarrhœa was readily checked, but immediately afterward he had an attack of jaundice, which was treated with iodide of potassium and three grains of blue mass every other night. Under this treatment he appeared to improve rapidly, and by the 3d of March the conjunctivæ had almost regained their normal color, and the iodide of potassium was discontinued. It appears that the same evening he went to the sutler's and indulged freely in apple-pie, and about 2 A. M., March 4th, was seized with severe pain in the abdomen, accompanied by violent spasms. The nurse in attendance did not summon the attending physician until half-past seven next morning, at which time the surface of the body was of a purple hue and cold, saliva flowing from the mouth, the spasms frequent and intense. Stimulants and external friction were resorted to, but without effect. He died during the day. *Autopsy* twenty-six hours after death: The middle lobe of the right lung was hepatized. The valves of the heart were slightly thickened. There was a small quantity of serum in the peritoneal cavity. The spleen was large and soft. The glands of Peyer congested. An oval gall stone, three quarters of an inch long by one-third of an inch thick, was found in the gall-bladder.

CASE 533.—Private Edward Dorsey, company A, 3d Maryland volunteers; age 32; admitted April 26, 1865. Chronic diarrhœa. The patient was in an exhausted condition, and had marked typhoid symptoms, viz: pain in the right iliac region, sudamina, tongue coated and cracked, frequent pulse and delirium; the discharges from the bowels were bloody. Treatment: Tonics, astringents, anodynes and stimulants. A nourishing diet was ordered, but the patient was able to eat very little. Died, May 1st. *Autopsy* ten hours after death: The meninges of the brain were much congested, and a small quantity of serum was found at the base of the brain. The lungs were normal. There was a cicatrix (?) on the surface of the liver two inches long by half an inch broad. The mucous membrane of the cæcum was covered with large ulcers, many of which had nearly perforated. Evidences of general peritonitis were observed.

CASE 534.—Private Calvin Burdick, company F, 31st Illinois volunteers; age 22; admitted from regimental hospital near City Point, Virginia, May 10, 1865. Diarrhœa. Had been sick several weeks; was suffering from diarrhœa, and was somewhat emaciated and much debilitated, though he was able to sit up and walk about a little. The day after admission, while walking out of doors, he suddenly fell to the ground, was carried into the ward, and expired a few minutes after. *Autopsy* twenty-four hours after death: An abundant deposit of tubercles was found in both lungs; they were not softened, and were somewhat more numerous in the upper than in the lower portions of the lungs, and in the left lung than in the right. The heart was soft and small, but otherwise normal. The liver and spleen were apparently normal. The mesenteric glands were enlarged, but contained no tubercular matter. The mucous membrane of the intestines was congested. The kidneys pale, but otherwise normal.

CASE 535.—Private Michael K. Smith, company G, 189th New York volunteers; age 41; admitted from regimental hospital May 15, 1865. Chronic diarrhœa. The patient was very low, and complained of pain in the region of the heart; on auscultation a blowing sound was heard. ℞. Blue mass and opium of each eight grains, extract of nux vomica two grains; make eight pills. Take one every three hours. This checked the diarrhœa somewhat, and the patient appeared to improve until May 23d, when he had a severe attack of erysipelas, and died May 24th. *Autopsy* six hours after death: The lower lobe of the right lung was hepatized. The pericardium contained four ounces of serum. The valves of the heart were thickened and closed imperfectly. The liver presented the nutmeg appearance; the gall-bladder was very much distended with bile. [The state of the intestines is not recorded.]

CASE 536.—Private Noah Casner, company G, 16th Michigan volunteers; age 45; admitted from regimental hospital May 24, 1865. Typhoid fever. Had severe diarrhœa and was in a typhoid condition. Treatment: Quinine, oil of turpentine, opium, stimulants by mouth and rectum. Died, June 6th. *Autopsy* eighteen hours after death: Lungs healthy. The mucous membrane of the small intestine was inflamed; that of the large intestine extensively ulcerated. The liver was fawn-colored.

CASE 537.—Private Oliver B. Quinn, company E, 128th Indiana volunteers; age 27; admitted from Soldiers' Rest February 20, 1865. Chronic diarrhœa and rheumatism. By May 16th the diarrhœa had ceased, but the patient presented the physical signs of phthisis. He had severe night-sweats, a troublesome cough, and profuse expectoration of very thick sputa mingled with blood. At times the diarrhœa recurred, but was always easily controlled by astringents. The general treatment consisted in the use of expectorants and tonics, with nourishing food and milk-punch. The patient was invariably in good spirits, expecting soon to be able to go home. Died, June 9th. *Autopsy* thirty-six hours after death: The left lung was infiltrated with tubercles, and had large cavities in its upper lobe; the superior lobe of the right lung also contained a very few tubercles. The mucous membrane of the intestines, especially of the ileum and cæcum, was inflamed; the solitary glands enlarged. The mesenteric glands were tubercular.

CASE 538.—Private John P. Phillips, company K, 42d Indiana volunteers; age 28; admitted from regimental hospital May 24, 1865. Chronic diarrhœa. The patient was much emaciated and greatly prostrated. Treatment: Astringents, camphor, opium and ipecacuanha. Died, June 12th. *Autopsy* twelve hours after death: The upper lobes of both lungs and the lower lobe of the left contained tubercular deposits, but there were no cavities. The liver was of a fawn-color. The mucous membrane of the intestines was inflamed. The mesenteric glands were enlarged.

CASE 539.—Private Nathaniel Sheppard, company C, 18th Wisconsin volunteers; age 28; admitted from regimental hospital May 9, 1865. Chronic diarrhœa. [This man appears on the register of the hospital of his regiment, near Raleigh, North Carolina, admitted April 16th—acute diarrhœa—sent to general hospital April 26th.] Was very much emaciated. Treatment: Astringents, Dover's powder, stimulants and suitable diet. The patient improved at first, but had a relapse June 6th, which resisted treatment. He became dispirited, stupid and lethargic. Died, June 13th. *Autopsy* six hours after death: The thoracic viscera were normal. The liver was much congested, the bile of a dark-red color. No intestinal ulceration was discovered.

CASE 540.—Private Lyman H. Cody, company A, 15th Michigan volunteers; age 30; admitted from Soldiers' Rest June 3, 1865. Chronic diarrhœa. The disease soon assumed a typhoid type. Treatment: Dover's powder, turpentine emulsion, camphor and opium, laudanum enemata, suppositories. Died, June 17th. *Autopsy* six hours after death: The upper lobe of the right lung was emphysematous. The pericardium contained five ounces of serum. The liver was enlarged, congested, and of a very dark color. The spleen enlarged and hard. The stomach empty. No ulceration was observed in the intestines.

CASE 541.—Private Michael Swift, company A, 17th Wisconsin volunteers; admitted July 22, 1865. He stated that he had suffered with diarrhœa over six months; is now emaciated to an extreme degree. To take camphor and opium pills; brandy. July 24th: Prescribed enemata of solution of chlorate of potassa. July 25th: The corneæ are becoming opaque. To rub the body with cod-liver oil. July 28th: The tongue is glazed, red, and has curdy flakes on its surface; but there has been less diarrhœa during the last forty-eight hours. July 29th: The tongue is less glazed, and the curdy flakes are less abundant. Last night the diarrhœa again became troublesome. To take pills of tannic acid and opium. July 30th: Vibices have made their appearance over the sternum; the hands and arms are cold; the stools are watery, frequent and involuntary. July 31st: The involuntary discharges continue; the patient is unable to swallow. Died, August 1st, at 3 A. M. *Autopsy* thirteen hours after death: Vibices on arms, legs and breast; slight rigor mortis in the upper extremities. The lungs were collapsed and pale; there were old pleuritic adhesions of the posterior and external portions of the right lung. The heart was normal, except that the foramen ovale was patulous. The lower part of the ileum was darkly injected, its mucous surface coated with whitish pseudomembrane. The colon was thickened, and there were a few ulcers in the caput coli and sigmoid flexure. The liver was normal. The spleen small, hard, its trabeculæ distinct. The kidneys large and fatty.—Acting Assistant Surgeon William C. Miner. [No. 596, Medical Section, Army Medical Museum, is from this case. The specimen is the heart, which is rather small; the foramen ovale is patulous, the opening passing obliquely through the interauricular opening; there is on each side of the passage a valve-like fold of the endocardium, by which the orifice was kept closed during life.]

CASE 542.—Private Curtis Cruiser, company K, 195th Ohio volunteers; age 19; admitted from his regiment October 10, 1865. Chronic dysentery. [This man appears on the hospital register of his regiment as under treatment for diarrhœa July 1st, August 19th, September 18th, and September 25th.] The evacuations being frequent, painful and scanty, camphor and opium pills were ordered, with a milk diet. October 13th: Had a chill last evening, followed by fever. To take five grains of quinine three times daily; laudanum enemata; brandy. October 14th: Is worse. To take an opium pill every four hours; brandy-punch every two hours. Died, October 15th. *Au opsy:* There were old pleuritic adhesions on both sides, but the lungs were healthy. The liver and spleen were normal. The colon was thickened, its mucous membrane coated with pseudomembrane.—Surgeon Edwin Bentley, U. S. V. [No. 666, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the colon thickened and presenting patches of pseudomembrane with many minute follicular ulcers.]

CASE 543.—Private Thomas Fitzgerald, company B, 1st Connecticut heavy artillery; age 30; admitted from regimental hospital September 27, 1865. Chronic diarrhœa. The patient was somewhat emaciated, and had been complaining about a month. He had daily from six to eight thin dark-brown stools, attended with much griping pain. To have half an ounce of castor oil with fifteen drops of laudanum at once, followed by five grains of Dover's powder every four hours. Diet: Milk-porridge, mutton-broth, boiled rice, toast and tea. October 1st: Is slightly improved; the stools are more consistent, and only from two to four daily. Continue treatment. October 15th: The stools are again thinner and more frequent. ℞. Subnitrate of bismuth, Dover's powder, of each one scruple; make four powders. Take one three times a day. October 20th: Is no better. Substitute pills of acetate of lead and opium. October 24th: Complains of severe pain in the abdomen. To take lime-water and milk during the day, and half a grain of sulphate of morphia at bed-time. October 27th: Still complains of some abdominal pain, but the stools are less frequent. To have fifteen drops of the tincture of chloride of iron three times daily. November 1st:

The stools are again more frequent, numbering six to eight daily; they contain mucus and blood. To have a laudanum enema after each stool. November 4th: Since the last report the stools have varied in number from two to four daily; they are dark and offensive. Continue the laudanum enemata, with the addition of a grain of nitrate of silver to each enema. November 6th: The stools continue as at last date, except that occasionally small masses of normal excrement are passed. Substitute injections of sulphate of zinc, one grain to the ounce of water, and give every six hours a pill containing one grain each of opium and ipecacuanha. November 10th: No improvement. The patient has become extremely emaciated; his hands and ankles are œdematous. Continue the pills; a laudanum enema after each stool. After this the patient grew rapidly worse, and died December 1st. *Autopsy:* Nothing abnormal was observed except in the colon, the mucous membrane of which was studded with follicular ulcers from the ileo-cæcal valve to the anus. The gall-bladder was moderately full of healthy looking bile.—Surgeon Edwin Bentley, U. S. V. [No. 673, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the colon, which is much thickened, and presents numerous follicular ulcers, with some adhering pseudomembrane. There are a number of stellate cicatrices between the ulcers.]

The next fifteen cases are from the case-book of the L'Ouverture Hospital, Alexandria, Virginia, Surgeon Edwin Bentley, U. S. V., in charge. All the patients were colored men, most of them sent to Alexandria from the hospital for colored troops, City Point, Virginia.

Case 544.—Private William Coleman, company E, 39th United States colored troops; age 24; admitted from regimental hospital June 17, 1864. Chronic diarrhœa and rheumatism. Died, July 13th. *Autopsy* eight hours after death: Body considerably emaciated. There was extensive inflammation of the mucous membrane of the whole intestinal canal, with considerable thickening of the cæcum, colon and rectum; no ulceration was observed. The other organs were healthy.

Case 545.—Private George Larue, company E, 31st United States colored troops; admitted from the field hospital August 9, 1864. Diarrhœa. Died, August 13th. *Autopsy* six hours after death: Body somewhat emaciated. There was some ulceration of the ileum, and general inflammation and thickening of the whole mucous membrane of the large intestine.

Case 546.—Private Joseph Bostwick, company C, 19th United States colored troops; age 56; admitted from the field August 9, 1864. Chronic diarrhœa [This man appears on the register of the hospital for colored troops, City Point, Virginia, admitted July 15th—remittent fever—sent to general hospital August 8th.] When first seen by the reporter, September 8th, he was extremely debilitated, but there was no diarrhœa, and no prominent symptoms of any kind. A nourishing diet was ordered. October 3d: Mild diarrhœa set in, which was readily checked by opium and tannic acid. The diarrhœa recurred October 9th, and resisted the anodynes and astringents which were employed. Died, October 12th. *Autopsy:* The whole intestinal canal was inflamed, but no ulceration was discovered. There was a small abscess in the left kidney. The other organs appeared to be normal.—Acting Assistant Surgeon E. P. Luce.

Case 547.—Private William Mason, company C, 28th United States colored troops; age 26; admitted from City Point October 31, 1864. Chronic diarrhœa of a typhoid type. [This man appears on the register of the hospital for colored troops, City Point, Virginia, admitted September 6th—diarrhœa—sent to general hospital October 30th.] Treatment: Astringents, anodynes and turpentine emulsion. Died, November 1st. *Autopsy:* The lower lobe of the left lung was congested. The intestines were highly congested, but not ulcerated. The kidneys much enlarged and granular.—Acting Assistant Surgeon Freeman Stoddard.

Case 548.—Private James Collins, company F, 43d United States colored troops; age 42; admitted from the hospital for colored troops, City Point, Virginia, October 31, 1864. Chronic diarrhœa. This man was brought to hospital in a very low condition. He was treated with astringents, anodynes, stimulants and beef-tea. Appeared to improve for about two days, but again became worse, and died November 4th. *Autopsy:* A large cavity was found at the apex of each lung. There were tubercles in the diaphragm, and very extensive inflammation of the whole intestinal canal.—Acting Assistant Surgeon Freeman Stoddard.

Case 549.—Private Joseph Allsop, company A, 30th United States colored troops; admitted from City Point, Virginia, October 31, 1864. Chronic dysentery. [This man appears on the register of the hospital for colored troops, City Point, Virginia, admitted October 3d—remittent fever—sent to general hospital October 30th.] Had been sick nearly three months. The discharges were bloody, and there was much abdominal pain. Died, November 4th. *Autopsy:* There was extensive ulceration of the large intestine, especially in the cæcum and rectum, where the ulcers were large and deep.—Acting Assistant Surgeon C. B. Bean.

Case 550.—Private Hiram Lamb, company D, 28th United States colored troops; age 55; native of North Carolina; three-quarters white; enlisted about January 1, 1864, but had been able to do but little duty, except as nurse at City Point hospital; admitted from the hospital for colored troops, City Point, Virginia, October 31, 1864, with chronic diarrhœa, from which he said he had suffered all summer. Treatment: Astringents, opiates, stimulants and light diet. He appeared to improve for a few days, but again declined, and died rather suddenly November 12th. *Autopsy:* The lungs were filled with tubercles, and in the apex of each were large cavities. The liver and spleen also contained tubercles. There were large and deep ulcers in the ileum, colon and rectum.—Acting Assistant Surgeon Freeman Stoddard.

Case 551.—Corporal Isaac F. Paul, company B, 27th United States colored troops; admitted November 17, 1864. Chronic diarrhœa, from which he stated he had suffered for three months. [This man appears on the register of the hospital for colored troops, City Point, Virginia, admitted August 20th—diarrhœa; no disposition.] He was much exhausted, greatly

emaciated, and had from eight to ten stools daily, with occasional vomiting. Treatment: Astringents and tonics, laudanum enemata, beef-tea, boiled milk and toast, milk-punch. Died, November 20th. *Autopsy:* The intestinal canal was extensively inflamed. Some ulcers were observed in the stomach. The spleen was extremely small, weighing only ten drachms and a half.—Acting Assistant Surgeon Frank Buckland.

CASE 552.—Private John Berry, company E, 29th United States colored troops; admitted November 17, 1864. Chronic diarrhœa. [This man appears on the register of the hospital for colored troops, City Point, Virginia, admitted September 6th—intermittent fever; no disposition.] Had been sick four months; was extremely weak and much emaciated. The stools averaged from eight to ten daily. To take pills of sulphate of copper, opium and tannic acid; enemata of castor oil and laudanum; boiled milk, toast and rice. He improved for a while, the stools being reduced in frequency to two or three daily, but speedily relapsed, and died November 25th. *Autopsy:* The ileum was inflamed; the cæcum, colon and rectum extensively ulcerated.—Acting Assistant Surgeon Frank Buckland.

CASE 553.—Private Solomon Dorsey, company B, 39th United States colored troops; admitted from the hospital for colored troops, City Point, Virginia, October 31, 1864. Ascites. Was first seen by the reporter November 19th. At that time he was very weak and much emaciated; had chronic diarrhœa, some cough, and was suffering from purulent otorrhœa in both ears. He was quite deaf, and complained of continual pain in the head. He seemed disinclined to answer questions. The cervical glands were enlarged. To take five grains of iodide of potassium three times daily; tincture of bark; nourishing diet; milk-punch; opiates at bed-time. Died, November 27th. *Autopsy:* Tubercular ulceration of both large and small intestine. The omentum was one mass of tubercle.—Acting Assistant Surgeon Frank Buckland.

CASE 554.—Private George Spriggs, company F, 19th United States colored troops; age 23; admitted November 17, 1864. Chronic diarrhœa. [This man appears on the register of the hospital for colored troops, City Point, Virginia, admitted September 13th—chronic diarrhœa—sent to general hospital November 16th.] He stated that he had been sick for a long time; was very feeble and much emaciated. Treatment: Astringents, tonics, anodynes, stimulants and light diet. He appeared to improve somewhat for a few days, but relapsed. Died, December 1st. *Autopsy:* The right pleural sac contained about two quarts of fluid, and there was also a considerable quantity in the abdominal cavity. The lymphatic glands at the root of the lungs were enlarged, and contained a hard deposit of tubercle. The entire omentum was one mass of tubercular deposit. The intestines were extensively inflamed, but there was no ulceration.—Acting Assistant Surgeon Freeman Stoddard.

CASE 555.—Private John Smith, company C, 29th United States colored troops; admitted from his regiment May 31, 1864. Inguinal hernia. When first seen by the reporter, September 9th, he was suffering from distressing dyspepsia, for which he was treated with gentian, quinia and other tonics, bismuth, stimulants, &c. Vomiting occurred constantly shortly after eating, even when the lightest diet was employed; nevertheless, his appetite seemed good. The pain after eating was so severe at times as to require anodynes. He had also occasional attacks of diarrhœa, lasting about a day, and ceasing spontaneously without the use of remedies. Between these attacks he was sometimes constipated, so as to require laxatives. At one time the abdominal pain was so severe that a blister was applied, with temporary relief. He finally refused medicine, and for more than a month took none except occasional anodynes when the pain was severe. December 5th: He was attacked with severe diarrhœa, the stools being cream-colored and yeasty in appearance. He failed rapidly, and died December 7th. *Autopsy* eighteen hours after death: Body much emaciated. The intestines were firmly adherent to each other and to the abdominal walls; they were extensively ulcerated. There was a double inguinal hernia.—Acting Assistant Surgeon E. P. Luce.

CASE 556.—Sergeant Elias H. Quillen, company C, 30th Connecticut volunteers, (colored;) admitted from the hospital for colored troops, City Point, Virginia, August 9, 1864. Chronic diarrhœa of about six months' duration; constant and annoying cough. The diarrhœa improved under treatment, but the pulmonary symptoms steadily progressed. He became extremely emaciated, and died December 11th. *Autopsy:* Tubercles in the right lung; a cavity at its apex. The stomach and entire intestinal canal were much inflamed, but there were no ulcers.—Acting Assistant Surgeon W. R. Fletcher.

CASE 557.—Recruit William Diller, (colored;) admitted from Lincoln hospital October 27, 1864. Gastrodynia. [This man appears on the register of the Augur hospital, near Alexandria, Virginia, admitted October 8th—remittent fever—sent to general hospital October 17th; and on the register of the Lincoln hospital, Washington, D. C., admitted October 18th—diarrhœa—sent to general hospital October 27th.] He complained of dyspeptic symptoms, especially of pain and swelling in the stomach; but his appetite was good, and he did not seem to be very sick. Occasionally he had slight attacks of diarrhœa, which were easily controlled by astringents, until about November 20th, when severe diarrhœa set in, which did not yield to treatment. There was some abdominal tenderness, but it was not thought that he was dangerously ill until a few hours before death. Died, December 15th. *Autopsy:* The ileum and large intestine were extensively ulcerated, and there were a number of perforations. [The record does not state whether in the small intestine or the large.] There was an extensive deposit of tubercle in the mesentery. The intestines were firmly adherent to each other and to the abdominal parietes.—Acting Assistant Surgeon Freeman Stoddard.

CASE 558.—Private William Wood, company D, 39th United States colored troops; age 37; admitted from City Point October 31, 1864. Diarrhœa and hemorrhoids. [This man appears on the register of the hospital for colored troops, City Point, Virginia, admitted September 6th—pneumonia—sent to general hospital October 30th.] Treatment: Astringents and anodynes. In a few days he ceased to be troubled with the hemorrhoids, but the diarrhœa, though relieved from time to time, frequently recurred. The patient grew gradually weaker, and became more and more emaciated. January 9, 1865: He complained in the morning of considerable pain in the limbs, but did not appear to be in a critical condition. He died about noon the same day. *Autopsy:* The pericardium contained some five or six ounces of bloody serum. The heart was quite flabby. The intestines were somewhat congested, but no ulcers were discovered.—Acting Assistant Surgeon Freeman Stoddard.

The next fourteen cases are from the case-book of the FAIRFAX SEMINARY HOSPITAL, near Alexandria, Virginia, Assistant Surgeon Harrison Allen, U. S. A., in charge:

CASE 559.—Private William Brophy, company D, 56th Massachusetts volunteers; age 46; admitted from the depot hospital of the 9th Corps, City Point, Virginia, July 24, 1864. Chronic diarrhœa. Died, July 26th, at 9.45 A. M. *Autopsy* seven hours after death: Body much emaciated. Near the ileo-cæcal valve were several ulcerations of Peyer's patches; one of them, about two inches from the valve, was two and a half inches long by one and a half broad, and penetrated to the peritoneum; the intestinal coats for ten inches below the ileo-cæcal valve were strongly injected, somewhat thickened, and presented several small ulcers; five inches below the valve one of the ulcers had perforated.

CASE 560.—Private Albert Smith, company D, 27th Michigan volunteers; age 19; admitted from the depot hospital of the 9th Corps, City Point, Virginia, July 24, 1864. Diarrhœa. Has from ten to fifteen passages daily; can retain nothing on his stomach; tongue furred and fissured, but moist. To take a camphor and opium pill every three hours. Tarragona wine; milk diet. July 25th: Abdomen tender on pressure; stools fluid and clay-colored. Continue treatment, and add two grains and a half of subnitrate of bismuth every four hours. July 26th: Is somewhat better; seems more cheerful, and has a little appetite. July 27th: Continues to improve; is able to sit in a chair outside of the ward. July 29th: Got up to stool, fell down suddenly, and expired in a few minutes. *Autopsy:* The ileum was inflamed throughout, but no ulcers were found. The spleen was very soft and dark, five and a half inches long by three and a half broad; the kidneys somewhat congested. All the other viscera normal.—Acting Assistant Surgeon Edward David.

CASE 561.—Musician Thomas Barney, 2d Pennsylvania heavy artillery; age 41; admitted from the depot hospital of the 9th Corps, City Point, Virginia, July 25, 1864. Chronic diarrhœa. The patient was in an extremely exhausted condition when admitted, and died July 30th. *Autopsy* three hours after death: The thoracic viscera were healthy. The mucous membrane of the lower part of the ileum was inflamed and presented several ulcers just above the ileo-cæcal valve. The large intestine was extensively ulcerated, and two of the ulcers in the descending colon had perforated.—Assistant Surgeon Harrison Allen, U. S. A. [Nos. 329 to 331, Medical Section, Army Medical Museum, are from this case. No. 329 is a portion of the ileum taken from just above the ileo-cæcal valve, presenting a few small superficial ulcers. No. 330 is a portion of the transverse colon of the same patient, presenting several ulcers which penetrate to the muscular coat. No. 331 is a portion of the descending colon, presenting several ulcers, two of which have perforated.]

CASE 562.—Private William Farley, company E, 31st Maine volunteers; age 31; admitted from the depot hospital of the 9th Corps, City Point, Virginia, July 24, 1864. Had been attacked by acute rheumatism while before Petersburg about ten days previously. He was much debilitated; the joints of the lower extremities were swollen and tender; the bowels constipated. To take a dose of castor oil; chicken diet. July 26th: He was attacked with acute dysentery. Treatment: Paregoric; boiled milk diet. July 27th: Ordered powders of camphor, opium and ipecacuanha. July 28th: Added six ounces of brandy daily. August 2d: Substituted six ounces of Tarragona wine daily. He ran down rapidly, became comatose, and died August 6th, at 1.55 A. M. *Autopsy* next day: Body much emaciated. Larynx, lungs and heart healthy. Both large and small intestine were inflamed throughout, especially from the middle of the ileum downward; but no marked ulceration was observed. There was an intussusception twelve or fourteen inches from the ileo-cæcal valve and about twelve inches in extent; it was not accompanied by adhesions or other evidences of local peritonitis. Liver normal. Spleen six inches and a half long by four wide. Kidneys large and congested.—Acting Assistant Surgeon John H. Pierce.

CASE 563.—Private Joseph Faith, company I, 14th New York artillery; admitted from the field July 24, 1864. Chronic diarrhœa. [This man appears on the hospital register of his regiment, admitted June 27th—dysentery—returned to duty June 29th; admitted July 4th—diarrhœa—returned to duty July 5th; admitted July 7th—returned to duty July 8th; and finally sent to division hospital July 12th—diarrhœa and piles. He is borne on the register of the field hospital of the 1st Division, 9th Corps, admitted July 12th—hemorrhoids—sent to depot hospital July 17th. He appears on the register of the depot hospital of the 9th Corps, admitted July 17th—no diagnosis—sent to general hospital July 22d.]. When admitted he was in a dying condition. Surface cold and clammy; pulse scarcely perceptible; tongue dry and cracked; great thirst; severe abdominal tenderness; frequent liquid dirty-yellow stools, containing no blood or mucus. Directed boiled milk and port-wine. August 3d: Chicken diet. Died, August 6th, at 12.45 P. M. *Autopsy* twenty-four hours after death: Larynx healthy. Pleuritic adhesions on the right side, and two ounces of fluid in the pleural sac. Left lung, heart and liver healthy. Spleen very firm, six inches long by four broad. Peyer's patches were somewhat inflamed, and the cæcum was slightly ulcerated.—Acting Assistant Surgeon Joseph H. Robinson.

CASE 564.—Private Foster R. Soper, company H, 37th Wisconsin volunteers; admitted from the depot hospital of the 9th Corps, City Point, Virginia, July 24, 1864. Chronic rheumatism. He is very much emaciated; complains of pains all over his body; is very weak and nervous; pulse 100; says he had previously suffered from rheumatism; bowels loose. To take pills of camphor and opium; a teaspoonful of solution of morphia at bed-time; Tarragona wine July 26th: Had several green watery stools last night; complains of epigastric pains; the abdomen is tumid and tender. Continue treatment, adding stimulants and beef-tea. August 4th: Very restless last night; frequent vomiting of a dark-green fluid. To take three grains of the subnitrate of bismuth every four hours; injections of beef-tea. August 6th: Tongue dry and furred; is very weak and delirious; diarrhœa continues. To take tincture of catechu and laudanum; brandy. August 8th: Great stupor. Died at 6.30 P. M. *Autopsy* nineteen hours after death: Larnyx, lungs and heart healthy. Liver fatty; gall-bladder full. Spleen firm, four inches and a half long by three inches broad. Stomach somewhat inflamed, half full of dark-green bilious fluid. Colon much inflamed. Solitary follicles enlarged and ulcerated. Mesenteric glands normal.—Acting Assistant Surgeon Edward David.

CASE 565.—Private James Roberts, company L, 24th New York cavalry; admitted from the depot hospital of the 9th Corps, City Point, Virginia, July 24, 1864. Diarrhœa. He was much emaciated and extremely jaundiced. Died, August 25th, at 1 P. M. *Autopsy* five hours after death: Slight rigor mortis; body extremely emaciated. Lungs and heart healthy. The liver measured ten inches by seven and a half; it was of a dark brownish-red color and very firm, the acini distinct; the gall-bladder contained six ounces of a dark grumous viscid liquid. The spleen measured six by four inches, was very firm, dark beef-red in color. The small intestine was healthy. The large intestine was extensively ulcerated.

CASE 566.—Private Edward Colcord, 2d Battalion Veteran Reserve Corps; age 60; admitted August 20, 1864. This man, who was one of the hospital guard, came to surgeon's call on the morning of August 6th, complaining of diarrhœa, from which he said he had suffered more or less for six months. He was evidently debilitated; his complexion sallow and pale; tongue furred; pulse quick and small; skin hot and dry. He had thirst and anorexia; foul breath; slight nausea and eructations; flatulence; griping pains and tenesmus. The stools were from ten to fifteen daily, and consisted chiefly of thin frothy mucus mixed with blood. He was treated in quarters till August 20th, receiving at first a dose of castor oil and laudanum, followed, August 7th, by the following: ℞. Sulphate of quinia twelve grains, opium three grains, ipecacuanha one grain, blue pill six grains; make six pills. Take one every four hours. August 10th, the following was substituted: ℞. Tincture of catechu and wine of ipecacuanha of each half an ounce, tincture of opium two drachms. Take twenty-five drops every three hours. August 20th: He was so weak that he was admitted to hospital, and the following was prescribed: ℞. Tannic acid one scruple, sulphate of morphia one grain; make six pills. Take one every four hours. A tablespoonful of brandy every half hour. August 24th: Is very much prostrated; the evacuations are frequent and distressing. Substituted pills containing quinine, sulphate of copper and morphia for the former treatment. Continue the brandy. August 25th: The stools are passed involuntarily. Died, August 26th, at 7 A. M. *Autopsy* ten hours after death: The body was not much emaciated. The lungs were collapsed, dry, and contained much pigment. The heart was normal; its right ventricle contained a firm black clot of moderate size. The liver showed some tendency to cirrhosis at its anterior border; the gall-bladder was distended with thick greenish glairy bile. The spleen was of moderate size and very firm. The mucous membrane of the small intestine was pale; Peyer's patches were inconspicuous, and there was no ulceration. The mucous membrane of the large intestine was extensively coated with pseudomembrane, which in places was stained by the intestinal contents, giving it a blackish color. The pseudomembrane had separated in many places, leaving large ulcers from the edges of which the membrane hung in shreds. The kidneys were fatty and softer than normal; in the inferior part of the external surface of the right kidney there was a cyst of moderate size. The suprarenal capsules were friable and nodulated externally.—Assistant Surgeon Harrison Allen, U. S. A. [Nos. 383 and 384, Medical Section, Army Medical Museum, are from this case. No. 383 is a portion of the ascending, No. 384 of the transverse, colon; the mucous membrane of both is thickened, and presents a number of large deep ulcers which occupy a large portion of the surface; shreds of undermined mucous membrane hang from the edges of the ulcers.]

CASE 567.—Private Merritt D. Griswold, company F, 17th Vermont volunteers; admitted from Augur hospital, Alexandria, Virginia, August 11, 1864. Chronic diarrhœa. [This man appears on the register of Augur hospital, admitted August 8th—chronic diarrhœa—sent to general hospital August 11th.] Died, September 3d, at 2.10 P. M. *Autopsy* twenty-three hours after death: Pneumonia of both lungs, most marked at the apex of the right lung. Heart healthy. Liver fatty; gall-bladder distended. The spleen measured six inches by four; it was of natural consistence and dark-red color. There was marked ulceration in the ileum for six inches above the ileo-cæcal valve; the rest of the small intestine was healthy. The large intestine was not inflamed or ulcerated. Kidneys and suprarenal capsules healthy.—Acting Assistant Surgeon John H. Pierce.

CASE 568.—Private Owen Warren, company I, 45th Pennsylvania volunteers; admitted July 24, 1864. Chronic rheumatism. [This man appears on the register of the hospital of the 2d Division, 9th Corps, admitted July 9th—diarrhœa—sent to depot hospital July 15th. He is borne on the register of the depot hospital of the 9th Corps, admitted July 15th—sick—sent to general hospital July 22d.] Complained of pain in the back and extremities; appetite good; bowels regular, but had severe diarrhœa recently. August 5th: The diarrhœa recurred, and he continued to have two or three stools daily during the month; subsequently the stools became more frequent and profuse, and a severe cough set in, accompanied by much pain in the chest and profuse but easy expectoration. Treatment: Tonics, astringents, milk diet. Died, September 16th. *Autopsy* five hours after death: Body very much emaciated. The right lung contained some tubercles in its posterior portion, but was healthy anteriorly; there were firm pleuritic adhesions on the left side, and some tubercles in the apex of the left lung, but not so many as in the right. Heart large, pale and flabby; contained firm clots. Liver fatty; gall-bladder distended. The spleen measured five inches by three, was dark in color and very firm. The small intestine was healthy to within a foot of the ileo-cæcal valve, thence much inflamed. The large intestine was extensively ulcerated, some of the ulcers nearly perforated. Kidneys and suprarenal capsules healthy.—Acting Assistant Surgeon Joseph H. Robinson.

CASE 569.—Private Rennselaer Bailey, company G, 24th New York cavalry; admitted from the depot hospital of the 9th Corps, City Point, Virginia, July 24, 1864. Chronic diarrhœa. This patient had suffered from diarrhœa five or six weeks; was somewhat emaciated; had but little appetite; tongue coated with a white fur. About two weeks after admission he had an attack of paraplegia, which, after several days, confined itself to the right lower extremity. August 14th: He commenced to sit up and walk about, his gait at first resembling that of a drunken man. Died, September 16th, at 7 P. M., of chronic diarrhœa. *Autopsy* fifteen hours after death: Body much emaciated. Intestines inflamed throughout; slight ulceration above the ileo-cæcal valve. Spleen four inches by four. Other organs healthy.

CASE 570.—Private Landon Cram, company A, 10th Vermont volunteers; age 43; admitted October 10, 1863. Chronic diarrhœa of two months' duration, with eight to twelve stools daily. The patient was of small frame, feeble and much emaciated. To take quarter of a grain of nitrate of silver with half a grain of opium and one of quinine every three hours. Apply a sinapism to the stomach. Wine, eggs and milk diet. October 14th: Diarrhœa somewhat better. October 15th: Complains of sore throat. No ulceration or pseudomembrane could be detected on examination, but diphtheria was suspected. ℞. Tincture

of chloride of iron two drachms, sulphate of quinia twenty-four grains, sherry wine six ounces. Take a tablespoonful every three hours. The throat was mopped with a strong solution of nitrate of silver, and a gargle containing chlorate of potash and nitrate of silver was directed. Diet: Milk and eggs. October 16th: Great irritability of the stomach and some difficulty in swallowing. ℞. Creasote one drop, water four ounces. To take a tablespoonful every fifteen minutes. Milk-punch. October 18th: No better. Throat very much inflamed, stomach still irritable. ℞. Chloroform, oil of turpentine, olive oil, equal parts. Apply to the throat externally. Continue the prescription of October 15th. Apply a sinapism to the abdomen. The gastric irritability persisting, the following was prescribed: ℞. Chloroform two drachms, simple syrup five ounces. To take a teaspoonful every three hours. Died at 10 P. M. *Autopsy* sixteen hours after death: An examination of the throat disclosed well-marked diphtheria. There were pleuritic adhesions on the right side, and the lower lobe of the left lung was partly hepatized; in the superior lobe of the right lung were two abscesses, one as large as a filbert. [The condition of the intestinal canal was not recorded.]—Acting Assistant Surgeon John E. Smith.

CASE 571.—Private Andrew Miller, company D, 64th New York volunteers; admitted November 2, 1864. Chronic diarrhœa. [This man appears on the register of the hospital of the 1st Division, 2d Corps, admitted September 13th—fever—returned to duty September 25th; again admitted October 26th—pain in the heart—sent to depot hospital the same day. He is borne on the register of the depot hospital of the 2d Corps, City Point, Virginia, admitted October 26th—dyspepsia; no disposition recorded.] The patient was very much emaciated and so weak that he staggered in walking; skin muddy and covered with a bran-like desquamation; tongue flabby; sordes on teeth; marked abdominal tenderness, especially in the umbilical region; the evacuations were very frequent, sometimes bloody. To take a tablespoonful of Hope's camphor mixture every two hours, and a teaspoonful of solution of morphia at bed-time. The surface to be sponged. Beef-tea and boiled milk. November 3d: Evacuations very frequent, copious, watery and offensive; with one of the evacuations a large clot of blood was passed; some strangury and pain over the bladder; urine scanty and high colored. Continue treatment. Administered an enema of laudanum and starch-water twice during the day. Applied cloths wrung out of hot water to the hypogastric region. Five ounces of brandy. November 4th: Evacuations still from twelve to fifteen in the twenty-four hours; blood passed occasionally; urine passed freely and without pain. Substituted for Hope's mixture another containing creasote, catechu and laudanum. Brandy and tincture of cinchona every two hours. Died, November 6th, at 1 P. M. Mind clear throughout the case. *Autopsy* twenty-four hours after death: Body emaciated; abdomen distended. The whole length of the large intestine was extensively ulcerated, some of the ulcers almost perforating; the intestine was tender and readily broken. The other organs appeared healthy.—Acting Assistant Surgeon Chas. A. Rahter.

CASE 572.—Sergeant Abraham L. Vanderlin, company I, 124th New York volunteers; admitted from City Point, Virginia, November 2, 1864. Diarrhœa. [The register of the hospital of his regiment shows that this man was under treatment for bronchitis in March, 1864, and for diarrhœa in July and August. He appears upon the register of the depot hospital of the 2d Corps, City Point, Virginia, admitted August 11th—diarrhœa—transferred August 31st. He is borne upon the register of the field hospital of the 3d Division, 2d Corps, admitted September 8th—diarrhœa—sent to depot hospital October 19th. He again appears upon the register of the depot hospital of the 2d Corps, admitted October 19th—diarrhœa—sent to general hospital.] Died, November 7th, at 6.30 P. M. *Autopsy* nineteen hours after death: Body greatly emaciated. The heart was small and contained no clots. The pericardium contained about four ounces of fluid. Lungs normal. The liver measured eight inches by ten; the gall-bladder was contracted and nearly empty. The spleen measured five inches by three, was dark brown in color, and very firm. The pancreas was normal. The stomach was injected with blood, mainly in the larger curvature. The small intestine was slightly inflamed throughout; a few of the solitary glands were enlarged to the size of small peas, and had little ulcers at their apices. The large intestine was ulcerated throughout, especially in the rectum.

Specimens from three fatal cases of chronic diarrhœa were forwarded to the Museum from the army of the Potomac, during the summer of 1863, by Surgeon Edward L. Welling, 11th New Jersey volunteers. The names of the soldiers were not given, nor was any history of the cases furnished:

CASE 573.—Nos. 178 and 179, Medical Section, Army Medical Museum, are from a patient who died of chronic diarrhœa during the spring of 1863 in the field hospital at Windmill Point, Virginia. No. 178 is a portion of the sigmoid flexure; No. 179 is a portion of the rectum. In both specimens the mucous membrane is thickened, softened, and presents numerous ulcers which have evidently originated in the solitary follicles; the mucous surface between the ulcers is slightly coated with pseudomembrane.

CASE 574.—No. 285, Medical Section, Army Medical Museum, is a portion of the colon, the mucous membrane of which is greatly thickened and presents numerous irregular ulcers. From a patient who died of chronic diarrhœa in field hospital, army of the Potomac, in the summer of 1863.

CASE 575.—Nos. 286 and 287, Medical Section, Army Medical Museum, are from a patient who died of chronic diarrhœa in field hospital, army of the Potomac. The specimens are two successive portions of the colon, in which the mucous membrane is greatly thickened and presents numerous follicular ulcerations.

The next six cases are from the case-book of the DEPOT HOSPITAL OF THE FIFTH ARMY CORPS, City Point, Virginia, Surgeon W. L. Faxon, 32d Massachusetts volunteers, in charge:

CASE 576.—Corporal Francis A. Crane, company C, 16th Maine volunteers; admitted from the field hospital of the 3d Division, 5th Corps, January 2, 1865. Chronic diarrhœa. Died, January 13th. *Autopsy:* The lungs and heart were healthy.

The stomach was thin and pale. The spleen was natural in size, but rather hard. The liver and kidneys were healthy. The mucous membrane of the ileum was somewhat thickened. The large intestine very much thickened, and presented numerous ulcers in all parts from one extremity to the other; many of the ulcers penetrated to the muscular coat.

CASE 577.—Private Charles Later, company G, 198th Pennsylvania volunteers; admitted from the field hospital of the 1st Division, 5th Corps, January 3, 1865. Diarrhœa. Died, January 23d. *Autopsy:* There were pleuritic adhesions on the right side, some fluid in the right pleural cavity, and an abscess in the right lung; the left lung was the seat of a deposit of tubercles. The pericardium contained a quantity of serum. The liver weighed eighty-two ounces. The spleen weighed eight ounces. The mucous membrane of the large intestine was ulcerated throughout its entire length; the ascending and transverse colon distended with gas. The mucous membrane of the small intestine was softened but not ulcerated.—Assistant Surgeon G. H. Rugg.

CASE 578.—Sergeant Amos Swasey, 107th Pennsylvania volunteers; age 32; admitted from division hospital at the front January 17, 1865. Chronic dysentery. The patient was in a state of collapse; his face pale and cold; pulse thread-like; tongue pale but not coated. He stated that he had suffered with looseness of the bowels for some time, and that about ten days ago he had passed suddenly a pint or more of blood; since then had bloody and muco-purulent stools at short intervals. On the right side the superficial veins of his abdomen and thorax were very much enlarged. During the seven days he survived there was but little change in his condition. His tongue continued clean to the last; his intellect was undisturbed; pulse 120 to 130 and thread-like; surface pale and cold, at times covered with a clammy sweat. The decubitus was on the right side, with the feet drawn up and head elevated; occasionally there was an expression of pain about his mouth, but he only admitted that he felt pain when he was moved. The evacuations from the bowels were small, frequent, dark colored, grumous, and had a fetid smell. They were checked by injections during the first three days, which afterward were of no avail. On the evenings of the 19th and 20th he became very faint and almost pulseless, but did not die until the 24th. The treatment was sustaining and stimulant throughout. *Autopsy:* Height five feet ten inches. Both lungs were completely adherent to the thoracic parietes, and had deposits of tubercle in their apices; the right lung weighed sixteen ounces, the left seventeen. The heart was healthy; it weighed seven ounces; its right auricle was filled with coagulated blood; the other cavities were empty. The mucous membrane of the stomach presented a number of minute ulcers. There were a few small ulcers about the middle of the jejunum, and some slight thickening of Peyer's patches. The colon was thickened and ulcerated. The liver weighed eighty-seven ounces; it had a large abscess on its under surface containing about a quart of pus; the apex of the abscess rested against the vena cava; the gall-bladder was full. The spleen was firm and pale; it weighed five ounces. The kidneys were pale; the right weighed four ounces, the left five.—Assistant Surgeon Granville M. Baker. [No. 478, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the greater curvature of the stomach, which presents a number of minute ulcers.]

CASE 579.—Private Andrew Musgrave, company B, 8th Maryland volunteers; admitted from the field January 30, 1865. Acute dysentery. Died, February 2d. *Autopsy:* Height five feet six inches. The right lung was healthy and weighed twelve ounces; its upper lobe was adherent to the thoracic parietes; the left lung was healthy and weighed fifteen ounces. The heart weighed ten ounces. The liver was pale and weighed fifty-seven ounces. The spleen was pale and soft, weight four ounces. The kidneys were pale; the right weighed four ounces, the left three ounces. The stomach was pale but apparently healthy. The ileum was injected and thickened for three feet from the ileo-cæcal valve. The colon was much thickened and ulcerated throughout its entire length; the edges of the ulcers were fringed with pseudomembrane. The mucous membrane of the rectum protruded through the anus about half an inch.—Assistant Surgeon G. H. Rugg.

CASE 580.—Private David C. Hollenbeck, company E, 188th New York volunteers; age 37; admitted from the field hospital of the 1st Division, 5th Corps, January 30, 1865. Chronic diarrhœa. Died, February 5th. *Autopsy:* The lower lobe of each lung was congested; the right lung weighed twenty-two ounces, the left fourteen ounces. The heart weighed nine ounces. The liver weighed fifty-two ounces; the spleen four ounces; the right kidney five ounces, the left four ounces. The mesenteric glands were enlarged and congested. The stomach was congested and contracted. The duodenum and jejunum were healthy, except that there was an intussusception two inches long about seven feet and a half from the stomach. There was a good deal of ulceration in the neighborhood of the ileo-cæcal valve, and a few ulcers scattered through the colon.—Assistant Surgeon Mathias L. Lord.

CASE 581.—Private George McCowen, company C, 107th Pennsylvania volunteers; admitted from the field hospital of the 3d Division, 5th Corps, February 2, 1865. Hepatitis. Returned to duty February 21st. Readmitted March 15th. Diarrhœa. Died, March 27th. *Autopsy:* There were no adhesions between the lungs and the thoracic parietes, but some slight ones between the several lobes of both lungs, and small spots of inflammation scattered through the parenchyma of both; the right lung weighed eighteen ounces, the left twenty ounces. The heart weighed ten ounces. The liver was granular and very soft; it weighed forty-two ounces. The spleen weighed seven ounces. The stomach, duodenum and jejunum were healthy. The ileum was congested in spots, but there were no ulcers. The colon was thickened and softened. The left kidney weighed nine ounces, the right eight ounces.

The next three cases are from the case-book of the DEPOT HOSPITAL OF THE SIXTH ARMY CORPS, City Point, Virginia, Assistant Surgeon J. Sykes Ely, U. S. V., in charge:

CASE 582.—Private George Bevius, company D, 77th New York volunteers; admitted from the field hospital of the 2d Division, 6th Corps, City Point, Virginia, March 15, 1865. Chronic diarrhœa. Died, March 15th. *Autopsy* forty-eight hours after death: Rigor mortis not well marked. Both lungs were distended with frothy serum. There were no pleuritic adhesions on either side. The left pleural sac contained about six ounces of bloody serum. The heart was large and filled with mixed

clots. The liver was congested and quite large, extending entirely across the abdomen; the gall-bladder was about two-thirds full of bile. The kidneys were large and congested. The omentum was contracted and thin. The transverse colon was distended with gas. No intestinal ulceration was detected. The mesenteric glands were enlarged.

CASE 583.—Private John Kauffman, company A, 61st Pennsylvania volunteers; admitted from the field hospital of the 2d Division, 6th Corps, April 24, 1865. Chronic diarrhœa. Died, April 30th. *Autopsy* twenty-two hours after death: No rigor mortis. There were slight pleuritic adhesions on the right side. The right lung was normal; the left lung was in the first stage of pneumonia. The heart, liver, spleen and stomach were normal. The mucous membrane of the intestines was congested but not ulcerated.

CASE 584.—Private Henry Mentor, company H, 1st Connecticut cavalry; admitted from Cavalry Corps hospital May 8, 1865. Diarrhœa. Died, May 13th. *Autopsy* sixty hours after death: Rigor mortis well marked. The lungs were congested and bound by firm adhesions to the thoracic parietes. The heart and liver were normal. The gall-bladder was distended with bile. The spleen and stomach were normal. No evidences of disease were recognized in the intestinal canal; and, in fact, nothing was discovered during the autopsy which could satisfactorily account for the fatal result.

Of the next two cases, the first is from the case-book of HOSPITAL No. 1, Beaufort, South Carolina, the second from a medical descriptive list; Surgeon Reed B. Bontecou, U. S. V., in charge at the date of the first case; Surgeon John Trenor, jr., U. S. V., at the date of the second:

CASE 585.—Private Sylvanus Bragdon, company K, 8th Maine volunteers; age 19; admitted September 22, 1862. Jaundice. Ordered a purgative dose of fluid extract of taraxacum, and the following day three grains of citrate of iron and quinine every three hours. September 24th: Ten grains of blue mass followed by castor oil. The patient was first seen by the reporter October 3d. He was still jaundiced and debilitated. The citrate of iron and quinia was continued. October 15th: Some dropsical effusion was noticed in the abdomen, and pain in the left hypochondrium was complained of. Ordered four grains of iodide of potassium every eight hours; a Dover's powder at night. October 20th: Complained of a troublesome cough, with some expectoration. A simple expectorant mixture was prescribed. October 25th: Cough is still troublesome, the expectoration purulent. Cod-liver oil was ordered, and the other medicines discontinued. October 27th: Diarrhœa having been induced by the cod-liver oil, it was discontinued. October 29th: Pleurisy has set in on the right side. A blister was applied to the lower part of the chest, and a quarter of a grain each of calomel, opium and ipecacuanha ordered to be given every five hours. Died, November 5th. *Autopsy* twelve hours after death: The right pleural sac contained a large amount of serum, and was lined by a layer of plastic lymph; the right lung was healthy; the left pleural sac was obliterated by ancient adhesions, and the apex of the left lung was solidified with tubercles, some of which had broken down, forming cavities the size of white beans. The heart and pericardium were normal. The abdomen contained about three pints of serum. The peritoneum was everywhere thickened, and all the abdominal organs were agglutinated together by thick recent lymph. The liver was large, and of a greenish-bronze color both externally and internally; the gall-bladder was filled with thin pale bile. The spleen was one-fifth larger than natural. The mucous membrane of the sigmoid flexure and transverse colon was livid, and presented traces of former ulcers. The large intestine was contracted to the size of an ordinary small intestine.—Surgeon Reed B. Bontecou, U. S. V.

CASE 586.—Private Lucius H. Jagger, 1st Connecticut light battery; age 22; admitted from hospital No. 2, May 17, 1864. Dyspepsia and diarrhœa. [This man appears on the register of hospital No. 2, Beaufort, South Carolina, admitted April 3, 1864; no disposition.] The patient was transferred to this hospital from hospital No. 2, where he had been under treatment since April 3d. He had received an injury from the limber of a gun, since which he had suffered from pain in the epigastric and left hypochondriac regions, distress, a fainting sensation, nausea and vomiting on taking food. Digestion and nutrition were very much impaired. His stomach retained nothing but farina, diluted boiled milk and soft boiled eggs, egg-nog and milk-punch. He was unable to retain beef-essence or solid food of any kind. Whatever his stomach did retain caused nausea, and frequently also vomiting. His bowels were sometimes loose, and then again constipated, irrespective of diet or treatment. Bismuth, nitrate of silver, and the bitter tonics were employed in the treatment, with magnesia to correct acidity, opiates and hyoscyamus to relieve pain, and counter-irritation to the epigastrium. At times, for a period of several weeks, no medicine was given, and the diet very carefully regulated. His condition was about the same with or without medical treatment. The diarrhœa gradually grew worse, and he died July 17th. [There is no record of the autopsy.]—Acting Assistant Surgeon Charles T. Reber. [No. 333, Medical Section, Army Medical Museum, is from this case. The specimen is the stomach, which is thickened, its rugæ conspicuous, and the mucous surface thinly coated with pseudomembrane.]

The notes of the next two cases were forwarded, with the specimens, from HOSPITAL No. 3, Beaufort, South Carolina, Assistant Surgeon F. Townshend Dade, U. S. V., in charge:

CASE 587.—Private Alonzo Hanse, company G, 8th Maine volunteers; admitted November 16, 1862. Chronic diarrhœa. He was very much emaciated, and had been suffering with diarrhœa about two months. He had frequent and copious evacuations, but without fever or tenesmus. The skin was dry, the urine scanty and high colored. He complained of pain in micturition, and also of pain along the whole track of the colon; he had some little nausea, and complained of a sinking sensation in the abdomen. He was given a hot bath at first, and rubbed well with coarse towels; a blister was then applied over the track of the colon. Injections of starch-water and laudanum were used three times daily, and he took every three hours a pill containing

half a grain of opium, three grains of camphor, and two of sulphate of quinia. Egg-nog was given freely, and as diet he had eggs, boiled meat, beef-tea, &c. Upon this treatment he improved rapidly for several days. His stools became less frequent, the pain disappeared, and it was thought he would soon recover. Instead, however, he became suddenly worse, had more pain, more frequent stools, and passed a great deal of mucus with them. Injections of nitrate of silver, ten grains to the ounce of water, with a little laudanum, were then resorted to with temporary relief; but the patient again became worse, and died December 4th. *Autopsy:* The colon and rectum were extensively ulcerated, and a quantity of coagulated lymph was deposited upon the ulcerated surface. The other organs were healthy.—Assistant Surgeon F. Townshend Dade, U. S. A. [Nos. 71 to 74, Medical Section, Army Medical Museum, are from this case. The specimens are successive portions of the colon, which is much thickened; the mucous membrane irregularly eroded, leaving innumerable little islets intact, so that the whole has a granulated appearance. There is an irregular deposit of pseudomembrane on the ulcerated surface.]

CASE 588.—Corporal Isaac Wike, company F, 55th Pennsylvania volunteers; admitted December 9, 1862. Chronic diarrhœa. [This man appears on the register of the hospital of his regiment, admitted September 5th—remittent fever—sent to general hospital September 12th. He is borne on the register of hospital No. 2, Beaufort, South Carolina, admitted September 12th—dysentery—returned to duty October 23d. He again appears on the register of his regiment, admitted October 30th—debility—returned to duty November 1st; and again taken sick December 9th—dysentery—sent to general hospital the same day.] Died, December 25th. *Autopsy:* The colon and rectum were extensively ulcerated. The two kidneys were fused together at their inferior extremities by an isthmus about an inch and a half across; each kidney has its ureter and bloodvessels complete.—Assistant Surgeon F. Townshend Dade, U. S. V. [No. 23, Medical Section, Army Medical Museum, is from this case. The specimen is the double kidney above described.]

The following case was forwarded on a medical descriptive list from HOSPITAL No. 6, Beaufort, South Carolina, Assistant Surgeon Edwin D. Buckman, U. S. V., in charge:

CASE 589.—Private John F. Murray, company C, 29th Connecticut (colored) volunteers; age 45; admitted from regimental hospital April 30, 1864. Chronic dysentery. The regimental surgeon stated that this patient had been sick for several weeks. He has now frequent desire to go to stool, severe pain and tenesmus. The stools are fetid, dark colored, and mixed with shreds of lymph. There is fever and great constitutional disturbance. The tongue is furred; the pulse quick and small. There is anorexia and great prostration. To take powdered opium half a grain, acetate of lead one grain, every four hours. Stimulants, farinaceous diet and milk. May 1st: No improvement. Treatment continued, with opiate enemata. May 2d: Pulse weaker; tongue dry and red; bilious vomiting in the evening. Treatment continued. May 3d: To take powdered opium one grain, and blue pill two grains, every four hours. May 4th: No improvement. Treatment continued. May 5th: Frequent hæmorrhage from the bowels; the patient is much prostrated. To take twenty drops of oil of turpentine every six hours; whiskey and quinine. May 6th: Hiccough has set in; is greatly exhausted; abdomen tense, full and tender on pressure. Treatment continued. Died, May 7th. *Autopsy:* The large intestine was extensively ulcerated. The mesenteric glands were enlarged.—Acting Assistant Surgeon J. M. Matlack.

The next three cases are from CAMP DENNISON HOSPITAL, near Cincinnati, Ohio. The first two were forwarded on descriptive lists, Surgeon B. Cloak, U. S. V., in charge; the last is from the case-book of the hospital, Surgeon C. McDermont, U. S. V., in charge:

CASE 590.—Private William G. Hillman, company A, 2d Ohio heavy artillery; age 21; admitted August 17, 1863. Acute dysentery. The patient was much prostrated and had about forty bloody stools in the twenty-four hours. There was a great deal of tormina and tenesmus; the tongue was red; the pulse quick and feeble. ℞. Sulphate of magnesia two ounces, powdered opium two grains. Take at one dose. Cups to the abdomen. August 20th: Stools not so frequent, but still bloody and accompanied by a great deal of pain. Gave a dose of castor oil and laudanum. August 25th: Tongue red, fissured and dry; but little appetite. ℞. Acetate of lead one scruple, powdered opium ten grains, powdered ipecacuanha five grains; make twelve powders. Take one every three or four hours. Injections of laudanum and starch-water. August 31st: Discharges not so bloody and less frequent; appetite improving. Treatment continued. September 1st: Had four passages from the bowels in the last twenty-four hours; no blood. ℞. Nitrate of silver three grains, sulphate of morphia two grains, wine of ipecacuanha one drachm, camphor water one ounce. Take a teaspoonful every two hours. September 3d: The patient has taken cold and the glands of his neck are enlarged. Treatment continued. Apply tincture of iodine to the neck. September 4th: Has more fever, some cough, and considerable dyspnœa. Complains of pain in the chest and abdomen; pulse frequent and thread-like; tongue and lips very dry; sordes on the teeth. Take ten grains of Dover's powder at bed-time; counter-irritation over the chest and abdomen. September 7th: The patient is delirious at times and is gradually growing worse. His breathing is constrained, short and accelerated; the sputa have acquired considerable viscidity. There is dulness on percussion and bronchial respiration on both sides. The patient lies on his back. His delirium takes the form of dread lest he should be captured by the enemy. (He is a refugee from Virginia.) ℞. Sulphate of quinia twenty grains, opium three grains, ipecacuanha five grains; make twelve powders. Take one every four hours; also a teaspoonful of turpentine emulsion every four hours, and free stimulation. Died, September 13th. *Autopsy:* A considerable portion of both lungs was hepatized. The mesenteric glands were enlarged. The mucous membrane of the rectum was inflamed.—Acting Assistant Surgeon J. N. Van Metre.

CASE 591.—Private William Rose, company D, Tod's scouts; age 20; admitted September 12, 1863. Dysentery. The patient was attacked about three weeks before admission. He has from thirty to forty passages daily; the stools are small, very offensive, and full of blood and mucus. There is a great deal of tormina and tenesmus; occasionally there is vomiting. The patient is extremely emaciated. ℞. Calomel eight grains, opium six grains; make ten powders. Take one every three

hours. September 20th: The dysenteric symptoms have subsided, but the patient is much weaker. The passages are now thin, copious, exceedingly offensive, of greenish color. There is but little pain. Prescribed dilute nitric acid with morphia and port wine. Boiled milk diet. October 1st: The diarrhœa continues unchanged. The stomach is so irritable that no solid food is tolerated. There is considerable abdominal tenderness. Continue treatment, and give also injections of sulphate of zinc, two grains to the ounce of water, after each stool. October 7th: Still vomits; tongue dry and cracked. Ordered turpentine emulsion, milk-punch, beef-essence. Died, October 9th. *Autopsy* next day: Both lungs were partially hepatized. The omentum and mesentery were congested. The mesenteric glands were enlarged; and the mucous membrane of the ileum, colon and rectum was inflamed, thickened and ulcerated in many places.—Acting Assistant Surgeon Chauncey D. Palmer.

CASE 592.—Private Martin Goodens, company C, 2d Ohio cavalry; age 17; admitted December 27, 1864. Chronic diarrhœa and ascites. [This man appears on the register of hospital No. 1, Nashville, Tennessee, admitted from his regiment December 13th—ascites—transferred to Louisville December 14th; and on the register of the Jefferson hospital, Jeffersonville, Indiana, admitted December 15th—dropsy from disease of the liver—transferred to Camp Dennison December 26th.] Died, March 8, 1865. For some time before death the patient vomited incessantly. *Autopsy* eight hours after death: The thoracic viscera were not examined. The omentum was adherent to the anterior walls of the abdomen. The abdominal cavity contained more than a gallon of fluid. The mesenteric glands were enlarged. The mucous membrane of the intestines was studded with ulcers, and there were deposits of tubercle on the peritoneal coat.

The following case is from the case-book of the GALLIPOLIS HOSPITAL, Ohio, Surgeon Lincoln R. Stone, U. S. V., in charge:

CASE 593.—Private Robert Armstrong, company A, 1st New York cavalry; age 32; admitted March 20, 1865. Chronic diarrhœa. [This man appears upon the register of the post hospital, Charleston, West Virginia, admitted September 20, 1864—chronic diarrhœa—sent to general hospital March 20, 1865.] He had been sick several months and was very much emaciated. He had six or eight passages daily; the stools were light colored, contained a good deal of mucus and pus, and were accompanied by great tenesmus; pulse 85; tongue furred; skin dry. ℞. Ipecacuanha eight grains, persulphate of iron fifteen grains, catechu fifteen grains, opium five grains; make eight powders. Take one every two hours. Milk diet. March 21st: Is somewhat better. Continue treatment; give also quinine and iron. March 22d: Diarrhœa continues; has some cough. Continue treatment; add a cough mixture containing squill and paregoric. March 24th: The diarrhœa still continues. Substitute the following: ℞. Persulphate of iron one scruple, tannic acid ten grains, opium five grains; make ten pills. Take one every three hours. March 28th: There is no change in the condition of the patient. Stop medicines and substitute the following: ℞. Fluid extract of gentian and tincture of opium of each half an ounce, brandy seven ounces. Take a tablespoonful three times daily; also a tablespoonful of chalk mixture every two hours. March 29th: Feels better, and is able to sit up most of the time; the diarrhœa, however, continues. Substitute the following: ℞. Ipecacuanha five grains, catechu twenty grains, opium five grains; make five powders. Take one every two hours. Chicken soup. March 30th: Is cheerful and decidedly improving; tongue furred; stomach somewhat irritable. Continue the powders ordered yesterday, every three hours, and give five grains of calomel. March 31st: Toward evening, to-day, the patient, who had been writing home and seemed very much depressed, was allowed a drink of brandy. Subsequently he contrived to get at the brandy-bottle and drank to intoxication. He died next morning, April 1st, at 4 A. M. *Autopsy* nine hours after death: In this case there was a general transposition of the viscera from left to right. The lungs were normal. The heart was situated on the right of the sternum. The pericardium contained a large quantity of serum. The liver was situated in the left hypochondriac region; its right lobe was much smaller than the left; the gall-bladder was distended with bile. The stomach was situated in the right hypochondriac region, its greater extremity being situated to the extreme right. The spleen was situated on the right side. The cæcum was found in the left iliac region; thence the ascending colon rose, crossed the abdominal cavity as usual but in the opposite direction, and descended, forming the sigmoid flexure in the right iliac region. The lower surface of the liver and the stomach were adherent to the transverse colon; the spleen was adherent to the right kidney; the transverse colon was congested and ulcerated, the ulcers penetrating to the peritoneum. The rectum was very much thickened. Acting Assistant Surgeon J. B. Ruttan.

The next case was forwarded on a medical descriptive list from the SEMINARY HOSPITAL, Columbus, Ohio, Assistant Surgeon Gerhard Saal, U. S. V., in charge:

CASE 594.—Franklin Thomas, a drafted man, unassigned; age 38; admitted from Tod barracks July 16, 1864. Diarrhœa. The patient was originally admitted to this hospital with measles June 22, 1864, and was returned to duty July 4th. The attack was mild and uncomplicated. Convalescence seemed to be complete. He was readmitted July 16th with violent abdominal pains, profuse diarrhœa and great prostration. The administration of chalk mixture, quinine and opium, and stimulants, failed to check the disease, and he died July 18th. *Autopsy:* The intestinal mucous membrane was extensively inflamed, and there were large patches of ulceration.—Acting Assistant Surgeon Charles E. Boyle.

The next seven cases were forwarded on medical descriptive lists from WEST END HOSPITAL, Cincinnati, Ohio, Acting Assistant Surgeon John F. White in charge:

CASE 595.—Private Samuel Gibbs, company K, 14th Illinois cavalry; age 48; admitted July 15, 1833. Diarrhœa. At the time of admission the patient had severe diarrhœa and obstinate vomiting. He had been in the saddle three weeks, pursuing the Confederates under Morgan, and was quite exhausted. ℞. Capsicum and opium of each five grains, extract of gentian fifteen grains; make ten pills. Take one every four hours. Beef-essence and wine; extra diet. July 17th: The diarrhœa is better;

the vomiting continues. Prescribed a mixture containing subnitrate of bismuth. July 20th: The diarrhœa is entirely checked, but the vomiting continues and the patient is much exhausted. The skin is covered with cold clammy perspiration, the pulse almost imperceptible. Calomel in grain doses, repeated every fifteen minutes, was now prescribed, and allayed the vomiting in the course of the morning, but the patient continued to sink, and died July 21st. *Autopsy* twenty-four hours after death: Body much emaciated. The lungs were somewhat congested and contained a few crude tubercles. The heart was dilated, its walls quite thin. The liver was healthy. The stomach was somewhat congested. The intestines were distended with flatus. The mucous membrane of the jejunum and ileum was highly vascular and thickly studded with minute points of ulceration and deposits of tubercle. [Enlarged solitary follicles? The condition of the large intestine is not recorded.]—Acting Assistant Surgeon C. T. Simpson.

CASE 595.—Private Edward P. Capron, company F, 20th Michigan volunteers; admitted August 11, 1863. Chronic diarrhœa. The patient stated that he had suffered from diarrhœa since the 13th of May. He is now pale, anæmic, his tongue dry and coated with brown fur, pulse very feeble, extremities cold. Had a chill this morning. To have a sponge bath; citrate of iron and quinia; whiskey-toddy; beef-essence. August 12th: Had involuntary discharges from the bowels this morning. August 13th: Became comatose about six o'clock this morning; is covered with cold clammy perspiration; extremities cold; eyes staring; breathing abdominal. Died, August 14th, at 5 P. M. *Autopsy* twenty-two hours after death: The lungs were congested and the thoracic cavity contained a large quantity of serum. The heart was somewhat enlarged and contained large fibrinous clots. The liver and spleen were enlarged and congested. The mesenteric glands were enlarged. The mucous membrane of the small intestine was congested and presented several ulcers. [The condition of the large intestine is not recorded.]—Acting Assistant Surgeon C. T. Simpson.

CASE 597.—Private George B. Ruston, company C, 79th New York volunteers; age 33; admitted August 18, 1863. Diarrhœa and jaundice. This man had suffered from diarrhœa for some time before coming to hospital. He has now from ten to twelve yellowish watery evacuations daily. He is decidedly jaundiced; complains of pain in the abdomen and in the back; is somewhat emaciated and very feeble. Quinine, whiskey-toddy, beef-essence, &c. Died, August 19th. *Autopsy* twenty hours after death: Body not much emaciated. All the cartilages of the ribs were ossified with the exception of those of the second and third ribs. The lungs were congested. The heart was healthy. The liver and spleen were very large, soft, and engorged with blood. The small intestine was highly congested. [The condition of the large intestine is not recorded.]—Acting Assistant Surgeon C. T. Simpson.

CASE 598.—Private Walter Love, company K, 17th Michigan volunteers; admitted August 12, 1863. Chronic diarrhœa. Died, August 24th. *Autopsy* twenty hours after death: Body extremely emaciated. The heart and lungs were healthy. The omentum was devoid of fat; the mesentery much congested; the mesenteric glands enlarged. The mucous membrane of the intestines was congested and presented numerous minute points of ulceration.—Acting Assistant Surgeon C. T. Simpson.

CASE 599.—Private Jacob Sutton, company B, 17th Michigan volunteers; admitted August 12, 1863. Chronic diarrhœa. Died, August 31st. *Autopsy* twenty-four hours after death: Body extremely emaciated. The lungs were slightly emphysematous. The heart was normal. The liver and spleen were slightly congested. The intestinal mucous membrane was congested throughout, but no ulcers were found. The appendix vermiformis was distended with nearly an ounce of pus.—Acting Assistant Surgeon C. T. Simpson.

CASE 600.—Private Louis M. Brooks, company C, 36th Massachusetts volunteers; admitted August 12, 1863. Chronic diarrhœa. The patient has been sick five months. He is now quite weak and extremely emaciated. Has been free from diarrhœa for the last few days; complains of no pain. Whiskey-toddy. August 18th: The diarrhœa has returned. ℞. Sulphate of iron and sulphate of quinia of each six grains, opium three grains; make twelve pills. Take one three times daily. Extra diet. August 26th: Has some cough, with mucous expectoration; bowels still loose. Stop the pills. ℞. Compound tincture of lavender one ounce, tincture of opium one drachm, white sugar two drachms, camphor water three ounces. Take a tablespoonful after every loose passage. Beef-essence; whiskey-toddy. August 29th: The diarrhœa continues unchecked; the cough is unabated. Substitute a mixture containing subnitrate of bismuth. Died, September 3d. Became delirious a few hours before death. *Autopsy* thirty hours after death: Body extremely emaciated. There were extensive and firm pleuritic adhesions on both sides. The lungs were slightly congested. The abdominal viscera were agglutinated together. The omentum, entirely altered in structure, was adherent to the anterior parietes of the abdomen and to the intestines. There were numerous blood-vessels in the adhesions. The intestines were so firmly bound together that no examination of their mucous membrane was made. The liver was normal but firmly adherent, as was also the spleen, which was thickly studded with tubercular deposits. The mesenteric glands were much enlarged and softened.—Acting Assistant Surgeon C. T. Simpson.

CASE 601.—Private Solomon Stockwell, company E, 27th Michigan volunteers; age 21; admitted August 12, 1863. Chronic diarrhœa. When admitted, this patient, besides his diarrhœa, had tertian intermittent fever. He was very much debilitated, pale and anæmic. The intermittent fever was of later date than the diarrhœa. He had a paroxysm yesterday. Prescribed quinine. August 14th: Has had no chill since admission, and no diarrhœa. His general condition is about the same. Quinine and iron. August 18th: Had a chill to-day. Continue treatment. August 24th: Has had no chill since the 18th; is very weak; pulse feeble. Stop all medicines for the present. Whiskey-toddy, beef-essence, eggs, &c. August 25th: Was somewhat delirious last night. The diarrhœa has recurred; pulse 144 and very feeble; extremities cool. Milk-punch, beef-essence, carbonate of ammonia. August 27th: There it still some delirium; he sleeps but little and is very restless. To take the eighth of a grain of sulphate of morphia at bed-time; repeat if necessary. August 28th: Took two doses of the morphia and slept all night. Feels much better this morning. The diarrhœa still continues. September 2d: The stools are dysenteric in character. Acetate of lead and opium. September 6th: To-day, for the first time, the patient has considerable cough. Bed-sores

are beginning to show themselves. Citrate of iron and quinine. Yeast poultices to the bed-sores. Milk-punch, beef-essence, &c. September 8th: Has numerous dysenteric stools. General condition about the same. ℞. Persulphate of iron ten grains, opium five grains; make ten pills. One every four hours. Continue stimulants. Astringent enemata. 'September 9th: Is very weak; 'slept but little last night; is nervous and restless; the bed-sores are more painful; tongue almost clean. Continue treatment. Tannate of lead to the bed-sores. September 11th: Had twenty-five stools last night; pulse 108 and quite feeble; skin cool; tongue very slightly coated; the stools are watery and dark colored. Substitute the following: ℞. Sulphate of quinine twenty grains, iron by hydrogen ten grains, opium five grains; make ten pills. One three times daily. Continue the injections. September 14th: Had nine operations last night. Still coughs; expectorates mucus; complains of pain in the epigastrium; the bed-sores are growing worse. Carbonate of ammonia, beef-tea and milk-punch. Died, September 25th. Was more or less delirious for the last thirty-six hours. *Autopsy* nineteen hours after death: Body much emaciated. The lungs were normal, except the upper lobe of the left lung, which was hepatized posteriorly. The pericardium contained about five ounces of serum. The heart was normal; its right cavities contained a large fibrinous clot. The liver was of a dark-purple color; the gall-bladder was distended with bile. The spleen was very soft and adherent to the abdominal parietes. The omentum was transformed into a soft gelatinous mass. The intestinal mucous membrane was highly congested, and the large intestine was ulcerated.—Acting Assistant Surgeon C. T. Simpson.

The next nine cases are from the case-book of the MADISON HOSPITAL, Madison, Indiana, Surgeon Gabriel Grant, U. S. V., in charge from the date of the first case to January, 1865; afterward Surgeon John H. Rauch, U. S. V.:

CASE 602.—Private Levi Engle, company I, 80th Ohio volunteers; admitted August 25, 1863. Chronic diarrhœa of six months' duration. The patient was debilitated and much emaciated; his pulse, which ranged from 80 to 90, was feeble but regular; the tongue was clean; the diarrhœa was not very troublesome, there being only three or four thin light-colored evacuations daily; his appetite was good. Generous diet and porter were prescribed. He gradually lost strength, and died September 5th. *Autopsy:* The small intestine and some portions of the large were congested, and there was some slight thickening of a portion of the sigmoid flexure, but no ulcers were found either in the small intestine or the upper portion of the large. There were, however, a few points of recent ulceration, and some few cicatrices of old ulcers in the lower part of the colon and upper part of the rectum. There were four intussusceptions in the small intestine, one nine inches in length, one four inches long, and the other two an inch each.—Acting Assistant Surgeon R. Charlton.

CASE 603.—Private John O'Brien, company F, 107th Indiana volunteers; admitted September 26, 1863. Chronic diarrhœa. [This man appears on the register of the Brown hospital, Louisville, Kentucky, admitted August 17th—chronic diarrhœa—sent to general hospital September 26th.] The patient was greatly debilitated and emaciated. September 27th: The following was ordered by Dr. Schultz: ℞. Citrate of iron and quinia two scruples, whiskey four ounces. Take a tablespoonful three times a day. October 16th: Ordered half a grain of sulphate of morphia twice a day. October 18th: Renew the citrate of iron and quinia with whiskey. October 28th: Dover's powder, in five-grain doses, to be used as needed. October 30th: Ten grains of blue mass in three pills, followed, after four hours, by a drachm of calcined magnesia. November 2d: Twenty grains of Dover's powder to be taken in three doses during the day. November 3d: ℞. Acetate of lead fifteen grains, powdered opium six grains; make six powders. To be used as needed. November 7th: The reporter took charge of the case. At this time the patient's tongue was red at its edges, its centre covered with a whitish fur; the dejections varied in number—some days there were only one or two, on others twelve to fifteen; they were fluid, dark in color, but not large; there was little or no abdominal tenderness; the appetite was good, but there was considerable thirst; the skin was dry and scaly; the motions were accompanied by but little pain, and there was no tenesmus. ℞. Acetate of lead fifteen grains, opium six grains, ipecacuanha three grains; make five powders. Take one every four hours. Milk-punch; gum-water as a drink. November 16th: Substitute the following: ℞. Subcarbonate of bismuth two drachms, opium and ipecacuanha of each five grains; make twelve powders. Take one every four hours. November 18th: Continue treatment. November 25th: The patient has slowly improved to this date. He was able to walk around, and the dejections seldom exceeded two or three daily; but as the stock of bismuth on hand was exhausted, the following was prescribed: ℞. Acetate of lead twelve grains, opium and ipecacuanha of each six grains; make six powders. Take one every four hours; also sponge the surface with alcohol. On thanksgiving day (November 26th) the patient unfortunately ate largely of turkey, dressing, &c. The result was the diarrhœa became worse than before. His bowels having been moved thoroughly, he was ordered to take pills containing each half a grain of opium and quarter of a grain of persulphate of iron. This was continued until December 10th, when, a fresh supply of bismuth having been received, it was again prescribed as before, and the patient steadily improved, the stools being again reduced in number to from one to three daily. December 25th, however, he was again suddenly taken worse. He now complained of nausea, and of pain in the right side over the region of the liver. He appeared weak and prostrated. A blister was applied to the side, and the following was ordered: ℞. Sulphate of quinia six grains, powdered capsicum one grain; make three powders. To take one three times a day. The stomach, however, was now so irritable that these pills were rejected, and in spite of the use of brandy, milk-punch, and beef-tea, he rapidly sank. He died December 30th. *Autopsy* eighteen hours after death: Body very much emaciated. The lungs and heart were healthy. The heart was firmly contracted, and contained in its right auricle a large fibrinous clot. The right lung was adherent throughout its whole extent to the pleura costalis. The liver was normal; the gall-bladder full of bile. The pancreas and spleen were normal. The inferior portion of the right kidney presented a cyst containing an ounce of fluid; in all other respects the kidneys appeared to be healthy; the bladder was full of urine. Upon raising the intestines the duodenum tore across without any violence having been used; it was found to be much softened. The rest of the intestines were healthy in appearance, except the rectum, which was congested, but not ulcerated or softened. The stomach contained about a pint of dark fluid resembling coffee grounds.—Acting Assistant Surgeon D. A. Morse.

CASE 604.—Private Ezra Stratton, company C, 33d Ohio volunteers; admitted April 8, 1864. Chronic diarrhœa. [This man appears on the register of the Cumberland hospital, Nashville, Tennessee, admitted February 25, 1864—gunshot wound of the right cheek—sent to Louisville April 4th. He is borne on the register of Clay hospital, Louisville, admitted April 4th—chronic diarrhœa—sent to general hospital April 7th.] The disease persisted, in spite of treatment, until April 17th, when pneumonia set in. The symptoms were cough, difficult expectoration, and severe pain in the chest. Crepitant rale was heard at the apex of each lung; the pulse was quick and feeble; the diarrhœa still persisted. Tonics and stimulating expectorants were prescribed, afterward stimulants. Died, April 20th. *Autopsy* twenty-four hours after death: Body very much emaciated; apparent age 21; height five feet four inches. The pericardium contained three ounces of serum. The heart was normal in size, but flabby. The middle lobe of the right lung was in the stage of red hepatization, passing into gray; the upper lobe of the left lung was in the stage of red hepatization; the rest of the lung-tissue was normal. The spleen was normal in size, but soft. The liver soft and engorged with blood. Both kidneys were normal. The stomach was normal. The colon was thickened, softened and congested. The descending colon and rectum were ulcerated. The bladder was distended with urine.—Acting Assistant Surgeon George F. Gill.

CASE 605.—Private Henry Playford, company D, 16th United States Infantry; age 28; admitted April 8, 1864. Chronic diarrhœa. [This man appears on the register of hospital No. 8, Nashville, admitted February 28th—acute diarrhœa—sent to Louisville April 6th; and on the register of Clay hospital, Louisville, admitted April 6th—chronic diarrhœa—sent to general hospital April 7th.] The patient was much emaciated and unable to walk about. The stools were frequent and copious. Treatment: Opium, stimulants, nutritious diet. He appeared to improve for a day or two; but on May 11th vomiting suddenly set in, and he died at 5 P. M. *Autopsy* twelve hours after death: The left lung was healthy; there were extensive pleuritic adhesions on the right side; the upper and middle lobes of the right lung were in the stage of red hepatization, the lower lobe much congested; a few softened tubercles were found near the root of the lung. The heart was small and firmly contracted; clots were found in both cavities, the largest being in the right side. The stomach contained some stercoraceous matter of a yellowish color; its mucous membrane was very much corrugated; a portion of it was coated with unhealthy looking mucus, and presented a few points supposed to be ulcers. The small intestine was healthy. The mucous membrane of the colon was congested, thickened and softened. The mesenteric glands were tubercular. The liver was abnormally friable. The spleen was healthy.—Acting Assistant Surgeon T. B. Gerard.

CASE 606.—Private A. S. Huntington, company K, 1st Wisconsin cavalry; age 32; admitted April 8, 1864. Chronic diarrhœa. [This man appears on the register of the Cumberland hospital, Nashville, admitted March 13th—chronic diarrhœa—sent to Louisville April 4th; and on the register of Clay hospital, Louisville, admitted April 4th—chronic diarrhœa—sent to general hospital April 8th.] When first seen by the reporter, May 1st, he was greatly emaciated; the discharges from the bowels were frequent, watery and very offensive. He died May 14th. *Autopsy* six hours after death: The pericardium contained about two ounces of serum. Both lungs were thickly studded with miliary tubercles and contained numerous vomicæ; the left lung was adherent posteriorly and to the diaphragm. The heart and its valves were normal. The liver, spleen and kidneys were also normal. The mucous membrane of the stomach was thickened and congested; no intestinal lesions, such as would account for the diarrhœa, were recognized. The mesenteric glands were tubercular, and some of them cretefied.—Acting Assistant Surgeon T. B. Gerard.

CASE 607.—Private Michael Sommers, company E, 45th New York volunteers; admitted June 29, 1864. Diarrhœa. [This man appears on the register of hospital No. 1, Nashville, Tennessee, admitted from Chattanooga May 24th—chronic bronchitis—sent to Louisville May 30th; and on the register of the Jefferson hospital, Jeffersonville, Indiana, admitted May 31st—chronic bronchitis—sent to general hospital June 28th.] The patient was delirious, extremely emaciated and greatly debilitated. He had frequent stools containing mucus and blood, cough and muco-purulent sputa. Coarse mucous rales could be heard on both sides of the chest. He died next day. *Autopsy* sixteen hours after death: Pleuritic adhesions, both old and new, were found on both sides, but there was no effusion into either sac. Both lungs were tuberculous throughout, and had very large vomicæ in their apices. The heart was flabby and contained large fibrinous clots. The stomach was congested. The small intestine was also congested. The large intestine was ulcerated throughout, more especially in the cæcum, which was much thickened; the ulcers were large and arranged transversely. The liver was friable. The kidneys were very large and flabby.—Acting Assistant Surgeon Joseph G. Rogers.

CASE 608.—Private John W. Wood, company F, 123d Indiana volunteers; age 19; admitted July 3, 1864. Diarrhœa and scrofula. [This man appears on the register of the Cumberland hospital, Nashville, admitted from Resaca, Georgia, May 26th—pneumonia—sent to Louisville June 5th; and on the register of the Joe Holt hospital, Jeffersonville, Indiana, admitted June 6th—diarrhœa—sent to Madison July 2d.] This man when admitted had some diarrhœa, cough, and enlargement of the lymphatic glands on the left side of the neck. He was very much emaciated. Tincture of iodine was applied to the glandular enlargements, and half an ounce of cod-liver oil and whiskey ordered to be taken three times a day. Full diet. July 26th: The diarrhœa is very troublesome and the patient very weak. He complains of sore throat; the enlarged cervical glands are painful. To take every four hours a pill containing a grain of opium and two grains of acetate of lead. Sherry wine; chicken diet. July 27th: The diarrhœa is less troublesome. Continue treatment; also egg-nog made with brandy given freely. July 28th: The patient is failing rapidly; his extremities are cold; pulse quite feeble. Died, July 29th. *Autopsy* ten hours after death: Body much emaciated; rigor mortis slightly marked. Brain not examined. Both lungs were congested, the left more so than the right, and both were adherent to the thoracic parietes, though the adhesions were not strong; they were more firmly adherent to the diaphragm. The bronchial tubes appeared to be thickened and contained a muco-purulent secretion. The right pleural sac contained four ounces of serum. The pericardium contained two ounces and a half of serum. The heart was normal. The abdomen was very prominent; upon opening its cavity it was found impossible to separate the viscera from the parietes. The peritoneum was greatly thickened (three-quarters of an inch thick anteriorly) and adherent to the intestines.

Pus was found in several places in the abdominal walls next to the peritoneum. All the abdominal organs were strongly inter-adherent—so strongly that it was impossible to separate them without dissection. The liver was large but apparently healthy. The spleen enlarged and friable. The kidneys were normal. The mesenteric glands were tubercular, and in places the lymph coating the knuckles of intestine had a cheesy character. The folds of intestine could not be separated except by dissection. The mucous membrane of the large intestine was thickened. The bladder was moderately distended with urine.

CASE 609.—Private Abraham Floyd, company G, 31st Indiana volunteers; age 35; admitted August 17, 1864. Chronic diarrhœa and scrofulous ulcers on the right leg. [This man appears upon the register of the Cumberland hospital, Nashville, Tennessee, admitted June 19th—sore arm from vaccination—sent to Louisville July 6th; and on the register of the Jefferson hospital, Jeffersonville, Indiana, admitted July 7th—ulcers of right leg—sent to Madison August 17th.] He was first seen by the reporter January 5, 1865. He was then greatly emaciated and very anæmic; the stools were frequent, liquid, and accompanied by severe pain; the abdomen was exceedingly tender; the tongue was clean and moist, but red; the pulse 90 and weak. Citrate of quinia and iron was prescribed in sherry wine, with a generous diet. He improved rapidly, and by the middle of February was thought to be so far recovered as to need no medicine. March 2d: He had a slight attack of jaundice which lasted about fifteen days, after which he again began to improve. On the first of April he complained of headache, vertigo, dizziness and weakness, and had sharp but transient pains in all parts of the body. He continued to grow worse for a week, when he had a slight chill, followed by fever, thirst, heat of skin, &c. His tongue now became dry and red; bowels loose; abdomen tympanitic and tender; pulse 100 and weak. There was great dejection of spirits, and occasionally mental aberration. On the 13th of April a rose-colored eruption was observed scattered over his abdomen and breast. He was treated with turpentine emulsion, wine and egg-nog. By the 20th he was apparently convalescing; his tongue was moist and his bowels more natural. April 23d: He complained of severe pain in the chest; pulse 120; bowels again very loose; tongue red but moist. Delirium of a low muttering kind now set in. Applied a sinapism to the chest, and prescribed a mixture containing fluid extract of ipecacuanha and veratrum viride, in addition to the turpentine emulsion. Stimulants as before. April 27th: There was retention of urine, requiring the use of the catheter. At 3 P. M. copious clammy perspiration set in. He died at 5 P. M. *Autopsy* sixteen hours after death: The brain was normal except that the Pacchionian bodies were unusually prominent. There were firm pleuritic adhesions on both sides. Both lungs were studded with miliary tubercles. The pericardium contained an ounce of serum. The heart was normal. The stomach was empty and healthy. The liver was pale and flabby; the gall-bladder contained five black gall-stones but no bile. The spleen was normal. The lower portion of the ileum was inflamed; the glands of Peyer were thickened. The descending colon was in a state of chronic inflammation and ulceration; several hard lumps of fæcal matter were found in the pouches of the colon.—Acting Assistant Surgeon John E. Frey.

CASE 610.—Private Peter Dawer, company C, 57th Illinois volunteers; age 45; admitted May 3, 1865. Chronic diarrhœa. [This man appears on the register of the field hospital of the 4th Division, 15th Corps, admitted April 2d—chronic diarrhœa—sent to general hospital April 3d. He next appears on the register of the hospital transport Ben Deford, taken on board at Hatteras Inlet, North Carolina, April 6th, sent to general hospital April 8th; and on the register of the McDougall hospital, New York harbor, admitted April 8th—chronic diarrhœa—sent to general hospital April 26th.] The patient stated that he was with General Sherman in his campaign to the coast, and was sent to McDougall general hospital, New York, from thence here; also that he had suffered from lung trouble every spring for the past three years. His chest presented evidences of frequent blistering. He was greatly emaciated; his skin sallow and dry. He had an obstinate cough, with white viscid sputa. He also suffered from an obstinate diarrhœa, having from fifteen to twenty stools daily. His lower extremities were œdematous, nevertheless, his appetite was voracious. He died May 18th. *Autopsy* twenty-four hours after death: Height five feet nine inches; rigor mortis slight; emaciation extreme. There were extensive pleuritic adhesions on both sides. The left pleural cavity contained twelve ounces of purulent serum. Both lungs were congested. The pericardium contained four ounces of serum. The heart and its valves were normal; both ventricles contained firm clots. The peritoneum contained about twenty ounces of bloody serum. The spleen was normal. The descending colon was ulcerated.—Acting Assistant Surgeon W. H. Sheets.

The next four cases were forwarded on medical descriptive lists from the HOSPITAL AT QUINCY, Illinois, Surgeon Robert Niccolls, U. S. V., in charge:

CASE 611.—Private William Bodle, company H, 3d Ohio volunteers; age 37; admitted February 15, 1863. Chronic diarrhœa. This man had been sick since October last. Has now from six to eight evacuations daily; is weak, very much emaciated, and has some cough; his tongue is clean; pulse natural. To take pills of sulphate of copper and opium three times daily. February 24th: Bowels not so loose. To take pills as occasion requires, and a drachm of elixir of cinchona at each meal with ale. March 1st: Is very hoarse; bowels loose again. Renew the pills. March 16th: Diarrhœa about the same. The patient coughs a little. His parotid gland is swollen, which was attributed to mumps, to which he had been exposed. To take three grains of quinia every four hours. March 20th: Pulse 100 and full; complains of pain in the lower part of the right side of the chest; has a severe cough and free expectoration. To take pills of quinine and iron. Low diet. March 21st: Bowels very loose; evacuations copious; pulse 120; skin hot; tongue furred. To take turpentine emulsion besides the pills. Low diet. March 22d: Pulse feeble; cough severe; complains of pain beneath the right nipple; bowels still very loose. Brandy every two or three hours. 6 P. M.: Has failed during the day; pulse nearly gone; sputa purulent and bloody; coughs constantly. March 23d: No better. Expectoration still continues; pulse very feeble. Died, March 24th, at 10.30 A. M. *Autopsy* twenty-four hours after death: The right lung was entirely hepatized and pus was infiltrated through its parenchyma; the lung was everywhere bound to the thoracic parietes by adhesions which appeared to be recent; the left lung was healthy, except some congestion of the upper lobe. The heart was healthy; fibrinous clots were found in both ventricles. The liver

and spleen were normal. The stomach was healthy. Some parts of the small intestine were darkly congested. [The condition of the large intestine is not recorded.]—Acting Assistant Surgeon F. K. Bailey.

CASE 612.—Private Harrison Lawrence, company G, 74th Indiana volunteers; age 46; admitted March 10, 1863. Diarrhœa. This man had been suffering with diarrhœa since October 26, 1862. When admitted he appeared to be in pretty good health. On the night of March 11th he was taken with a chill, followed by fever and some soreness of the throat. He complained of difficulty of breathing whenever he turned on his back. He stated that he had had frequent paroxysms of dyspnœa during the last four months. March 13th, at 8 A. M., he suddenly sprang out of bed, walked a few steps, and fell dead. *Autopsy* seven hours after death: A heart-clot was found in the right ventricle formed around an adventitious membrane [?], which fully explained the difficulty of breathing; also the sudden death. [There is no record of the condition of any of the other organs.]

CASE 613.—Private Hieronymus Weitner, company E, 16th Illinois cavalry; age 49; admitted September 14, 1863. Acute dysentery. The patient had been sick four days in camp near the city. When admitted his tongue was coated and red at the tip; skin moist; voice husky; face sunken. He had bloody stools, with tormina and tenesmus. ℞. Opium five grains, sulphate of quinia ten grains, mercury with chalk ten grains; make five powders. Take one every four hours. Low diet. September 15th: Symptoms unchanged, except that there was some nausea after taking the powders yesterday evening. Stop the powders. ℞. Opium five grains, camphor five grains; make five pills. Take one every four hours. September 16th: Bowels still very loose, with blood and slime; tormina severe; pulse 120. Continue the pills, with laudanum enemata. Low diet. September 17th: Discharges dirty-yellow and very offensive, but less in quantity. Continue the pills and enemata, with two grains of quinine every four hours. Beef-soup. September 18th: Has somewhat less pain; tongue coated white; pulse 120 and small. Continue quinine. Stop opium and camphor. Enemata as before. Soup. September 19th: Bowels moved frequently during the night. Continue treatment and diet. September 20th: Discharges thin and copious; tongue less coated but dry; pulse 130; stools very offensive. Stop quinine. ℞. Tannic acid one scruple, camphor twelve grains, opium eight grains; make eight powders. Take one every two hours. Continue enemata and diet. September 21st: Pulse 130; discharges less frequent, but the patient is becoming very weak; tongue dry and rough; respiration hurried. Continue treatment. Whiskey and water. Died, September 22d. *Autopsy* ten hours after death: Body emaciated; rigor mortis excessive. [The condition of the thoracic viscera is not recorded.] The liver, spleen, omentum, stomach and small intestine were healthy. The whole extent of the colon was much diseased; its peritoneal coat congested, and in the descending portion adherent to the abdominal parietes; the mucous membrane was disorganized, and all the coats were so soft as to be easily torn with the fingers.—Acting Assistant Surgeon F. K. Bailey.

CASE 614.—Private George S. Dean, 1st Iowa battery; age 24; admitted January 11, 1864. Chronic diarrhœa. Has had diarrhœa since July last. At present he has from five to seven discharges from the bowels daily; they are light colored and frothy. He also suffered during the fall and early winter with intermittent fever, but has had no chill since Christmas. He is now much emaciated; his eyes sunken and languid; tongue clean and red; pulse 100 and very weak. Treatment: Turpentine emulsion and pills of nitrate of silver and opium. Milk diet. January 25th: Is improving a little; says he feels stronger than when admitted. January 30th: Occupies his bed most of the time, and rests poorly at night. To take an opium pill at bedtime. February 4th: Complains of pain in the left shoulder. February 10th: The diarrhœa is improving; he has only three or four discharges daily, but still complains of pain in the left shoulder. February 16th: Has severe pain in the right breast, with dyspnœa; coughs frequently, and expectorates frothy sputa mixed with blood; the extremities are cold. Treatment: Quinine and opium with whiskey-punch; hot flannels, mustard to extremities, hot bath, &c.; but all failed to bring about reaction. Died, February 17th. *Autopsy* twelve hours after death: There were no pleuritic adhesions. The right lung was engorged with blood, its middle and lower lobes partly hepatized, sinking in water; the left lung was healthy. The pericardium contained half a pint of pale-yellow serum, its inner surface was roughened. The heart was somewhat enlarged; its right ventricle contained a large yellow fibrinous clot; its walls were thinner than usual; the left ventricle contained a small fibrinous clot The liver was enlarged, its peritoneal covering roughened, but no adhesions were discovered. The spleen was very much enlarged, weighing two pounds eleven ounces. The mucous membrane of the stomach presented points of inflammation. There were several ulcers in the ileum. The mucous membrane of the colon was disorganized by inflammation. No fluid was found in the abdominal cavity. The kidneys and bladder were not examined.—Acting Assistant Surgeon D. C. Owen.

The next sixty-nine cases are from the case-book of the HOSPITAL OF THE PRISON DEPOT, Rock Island, Illinois, Surgeon William Watson, U. S. V., in charge. All the patients were Confederate prisoners of war.

CASE 615.—Sergeant John L. Lewis, company I, 5th Tennessee; admitted May 7, 1864. Chronic diarrhœa. Died, November 1st. *Autopsy* six hours after death: There were extensive pleuritic adhesions on both sides. The heart was normal. The liver was congested; the gall-bladder very much distended with bile. The spleen was smaller than normal. The pancreas and kidneys appeared to be healthy. The mesenteric glands were enlarged and very much disorganized. The solitary follicles of the small intestine were ulcerated. The descending colon and rectum were extensively ulcerated.—Acting Assistant Surgeon H. H. Russell.

CASE 616.—Private Francis M. Carmichael, company F, 56th Alabama cavalry; admitted November 2, 1864. Acute diarrhœa. This man had measles last August, followed by intermittent fever. About the middle of September he had erysipelas of the face. November 1st, he was attacked with diarrhœa. The stools were frequent, muco-purulent and streaked with blood.

He had also severe pains in the left side and in the bowels. To take ten grains of blue mass with one of opium at bed-time; a mustard plaster to the side. November 3d: No better. To take a drachm of sulphate of magnesia and half a grain of opium every four hours. November 6th: Add an ounce of whiskey every four hours. Died, November 10th. *Autopsy* twelve hours after death: Body much emaciated. The right lung was highly congested. The heart was very large, but apparently healthy; no valvular disease. The liver and spleen were much enlarged and congested, and the peritoneum could readily be stripped off from them. The mucous membrane of the ileum was congested, softened and ulcerated in patches. The descending colon and rectum were extensively ulcerated and of a dark-bluish color.—Acting Assistant Surgeon Morris Hale.

CASE 617.—Sergeant James O'Grady, company A, 13th Louisiana; admitted April 16, 1864. Chronic diarrhœa. Died, November 13th. *Autopsy* twelve hours after death: Body extremely emaciated. The lungs, heart and liver were normal; the gall-bladder was distended with bile. The spleen was small but healthy. The pancreas and kidneys were normal. The mesenteric glands were very much enlarged. The descending colon and rectum were ulcerated. The mucous membrane between the ulcers was congested and softened.—Acting Assistant Surgeon H. C. Newkirk.

CASE 618.—Private Thomas F. Rowe, company D, 3d Georgia cavalry; age 42; admitted November 6, 1864. Diarrhœa. The patient was greatly debilitated and much emaciated; pulse 120, small and weak; tongue brown and dry; sordes on the teeth. He had frequent small stools attended by tenesmus, and the physical signs of pneumonia on the right side. Treatment: Nitrate of silver, opium, whiskey, &c. Died, November 15th. *Autopsy* twenty-four hours after death: The right lung was hepatized red. The pericardium was distended with fluid. The stomach, spleen and liver were normal; the gall-bladder was distended with a colorless albuminous liquid. The small intestine was highly inflamed, and presented seven intussusceptions. The rectum was ulcerated.—Acting Assistant Surgeon N. B. Matthews.

CASE 619.—Private John Davis, company B, 31st Alabama; age 20; admitted September 1, 1864. Chronic diarrhœa. This was a young man of slender frame, with blue eyes, light hair and complexion. He was treated for diarrhœa first by Dr. Mills, afterward by Dr. Young. The latter employed the sustaining and stimulant plan of treatment, giving quinine, iron and wine, with an occasional opiate, yet the patient continued to grow weaker, and began to have a slight cough accompanied by expectoration of large quantities of yellowish pus. November 10th: He was transferred to ward O with the diagnosis phthisis pulmonalis. He was still expectorating pus, but not so profusely as he had been doing; pulse 80 and weak; tongue red. There was a good deal of abdominal tenderness, especially in the region of the liver. The patient was very weak and feeble, and had no appetite. He had very little cough, but his diarrhœa still continued. His countenance was pinched and anxious. Treatment: Cod-liver oil, milk-punch, beef-tea, &c. A few days subsequent to his transfer to ward O he again commenced expectorating pus very freely; it appeared to be mixed with bile. He continued to expectorate freely till death, November 21st. *Autopsy* twelve hours after death: Body greatly emaciated. The blood appeared to be in an impoverished condition. The left lung was healthy; the right lung was adherent to the diaphragm. The liver was much enlarged and adherent to the diaphragm; it contained twelve distinct abscesses varying from the size of a hulled walnut to that of a goose-egg, and containing in all about a pint and a half of pus; one of these abscesses had discharged through the diaphragm and adherent right lung into the bronchial tubes; the gall-bladder was empty. The mesenteric glands were enlarged. The mucous membrane of the small intestine was congested; that of the colon and rectum ulcerated.—Acting Assistant Surgeon H. C. Newkirk.

CASE 620.—Private William C. Carpenter, company C, 26th Virginia; admitted November 11, 1864. Typhoid pneumonia. Died, November 21st. *Autopsy* twelve hours after death: The left lung was healthy. The right pleural sac contained a quantity of fluid. There were some pleuritic adhesions, and the right lung was coated with a large quantity of pus-like lymph. The right side of the heart contained clots which extended into the pulmonary artery. The mesenteric glands were enlarged, and there was ulceration of the colon and rectum.—Acting Assistant Surgeon H. C. Newkirk.

CASE 621.—Private Emory Hutchings, company E, 17th Texas; age 48; admitted October 18, 1864. Chronic diarrhœa. This man was captured September 15, 1863. He was first attacked with diarrhœa July 6, 1864, and has been twice in hospital on this account before his present admission. Is much emaciated; appetite very poor; skin dry and wrinkled; features shrunken, giving him the appearance of being older than he is. He has from ten to twelve loose stools daily, and complains of considerable pain and tenderness in the abdomen, particularly in the left iliac region. His feet and legs are œdematous, and both upper and lower extremities partially paralyzed. He is inclined to sleep all the time. To take a drachm of sulphate of magnesia and a grain of opium three times a day; ten grains of Dover's powder at bed-time. Milk-punch; nourishing diet. Quinine and iron were subsequently added. Under this treatment the diarrhœa improved, the œdema subsided, but the patient remained feeble and emaciated. The œdema of the legs returned November 15th, and by the 20th the hands and arms became œdematous. On the 22d the diarrhœa became worse, the stools increasing in frequency to five or six daily, and sometimes they escaped in bed. He died November 25th. *Autopsy* twenty hours after death: Near the base of the skull a large irregular bony protuberance was found, supposed to be the result of an ancient fracture. There were pleuritic adhesions on the left side, but the lungs were normal. The heart was flabby, and contained a well-washed white clot which extended four or five inches into the pulmonary artery on the right side. The blood in the great veins was thin and fluid. The liver and spleen were enlarged, congested and softened; the gall-bladder was distended with viscid bile. The mucous membrane of the intestines was congested and thickened throughout; in the colon and rectum it was extensively ulcerated. The mesenteric glands were enlarged and softened.—Acting Assistant Surgeon J. B. Young.

CASE 622.—Private Marshall Mitchell, company B, 3d Tennessee; age 40; admitted November 15, 1864. Diarrhœa and consumption. This man had a furred tongue; obstinate diarrhœa; pulse 120 and weak. His respiration was hurried and labored, and he complained of a sense of constriction or tightness across the chest. The lungs were clear on percussion, but

subcrepitant rale was heard on auscultation. There was scanty expectoration of tough viscid mucus. ℞. Rochelle salts one drachm, powdered opium half a grain, every four hours. Cod-liver oil three times a day. Died, November 26th. *Autopsy* twelve hours after death: Both lungs were emphysematous, and a few calcareous tubercles were found in the apex of each. The liver and spleen were small. The mesenteric glands were enlarged. The mucous membrane of the small intestine and of the colon was congested. The rectum was ulcerated.—Acting Assistant Surgeon H. C. Newkirk.

CASE 623.—Sergeant Leonidas Hedrick, company H, 1st Tennessee cavalry; admitted November 13, 1864. Diarrhœa. Died, November 27th. *Autopsy* twenty-four hours after death: Body much emaciated. The right lung was slightly congested; the left lung contained a deposit of tubercles and was hepatized gray. The heart was normal. The liver was fatty. There was an intussusception in the small intestine. The mucous membrane of the large intestine was ulcerated. The mesenteric glands were enlarged.—Acting Assistant Surgeon J. E. Brooke.

CASE 624.—Private Jackson Wiley, company I, 63d Georgia; age 24; admitted November 21, 1864. Typhoid pneumonia. This man when admitted had cough; hurried respiration; furred tongue; pulse 120 and weak. There was dulness on percussion, and mucous rales on both sides. The abdomen was tender on pressure. Died, November 27th. *Autopsy* twelve hours after death: Each pleural sac contained a quantity of serum. The right lung contained tubercles and was hepatized. The heart was large and contained large clots. The stomach was distended with gas. The small intestine was congested. The colon and rectum were ulcerated. The spleen was large and soft.—Acting Assistant Surgeon H. C. Newkirk.

CASE 625.—Private James H. Dorris, company D, 12th Arkansas; age 40; admitted August 27, 1864. Chronic diarrhœa. Died, November 27th. *Autopsy:* Both pleural sacs contained serum mixed with pus, and a large amount of pus adhered to the surfaces of the lungs. The heart was very small, the mitral valve diseased, and the walls of the left ventricle extremely thin. The intestinal mucous membrane was somewhat congested.—Acting Assistant Surgeon H. C. Newkirk.

CASE 626.—Private Peter White, company D, 63d Virginia; admitted November 9, 1864. Chronic diarrhœa. This patient had also scorbutic symptoms, and toward the last pneumonia. Died, November 28th. *Autopsy* seventeen hours after death: Almost the whole of the right lung was in the stage of red hepatization. The acini of the liver were pale; the interlobular spaces dark. [Congestion of the portal vein?] The colon was extensively ulcerated, and the rectum was almost gangrenous.—Acting Assistant Surgeon Washington Matthews.

CASE 627.—Ephraim Winfield, citizen of Missouri; admitted November 30, 1864. Diarrhœa. Died the same day. *Autopsy* one hour after death: Body pale and emaciated. The heart was normal in size; its valves healthy; its muscular substance had a pale-bluish color and was softer than usual. The apices of both lungs contained an excess of black pigment; there was a slight pleuritic adhesion on the left side; the right pleural cavity contained about eight ounces of serum; the posterior part of the right lung was in the stage of gray hepatization. The liver was normal; the gall-bladder distended with bile. The small intestine was congested, and there was an intussusception in the ileum. The transverse and descending colon were very much thickened, their mucous membrane presenting a gangrenous appearance throughout; near the centre of the transverse colon was an ulcer the size of a half dollar, which extended through all the coats. [Perforated?] The mesenteric glands were enlarged. The omentum was highly congested. The pelvic cavity contained about twelve ounces of sanious fluid, with some detached flakes of lymph. The other organs were normal.—Acting Assistant Surgeon H. H. Russell.

CASE 628.—Alfred Piles, Missouri guerilla; admitted November 24, 1864. Acute dysentery. No previous history. Died, December 1st. *Autopsy* twenty-four hours after death: The lungs and heart were normal. The intestines were distended with gas. The intestinal mucous membrane was much congested; in the rectum it was softened and ulcerated. The mesenteric glands were enlarged.—Acting Assistant Surgeon J. M. Witherwax.

CASE 629.—Private Warwick Butcher, company B, 19th Virginia cavalry; age 45; admitted September 28, 1864. Chronic diarrhœa. This man's general health was good before his enlistment in the Confederate army, March, 1862. He soon after had an attack of fever followed by rheumatism, from which he suffered most of the time he was in service. Was at home sick when captured, August 29, 1863, and was sent to Camp Chase, Ohio. He was ailing all the time while there, and at one time was in hospital with pneumonia, from which he recovered, but continued to have rheumatic symptoms until January, 1864, when he was transferred to Rock Island barracks. His general health at that time was moderately good, and continued so, with spells of indisposition, until August, when he was attacked by diarrhœa, which persisted until he was admitted to hospital. He then slightly improved until the weather became cold and snow fell, in the early part of November, when he took cold and grew rapidly worse. He was transferred to ward I November 14th; was first seen by the reporter on that day. He was then suffering from violent diarrhœa, and had a severe chill which lasted all the afternoon and until the next morning, when symptoms of pneumonia made their appearance. There was some fever and a very troublesome cough. The patient was restless, could not sleep, and had no appetite. The treatment was tonic and stimulant, with anodynes and expectorants. Died, December 3d. *Autopsy* five hours after death: Both lungs were full of miliary tubercles. The heart was normal. The blood was very thin and deficient in red corpuscles. The peritoneum covering the abdominal viscera and lining the abdominal parietes was studded with tubercles. The abdominal viscera were interadherent and the liver adhered to the diaphragm. The mucous membrane of the large intestine was thickened and softened. The lower part of the descending colon and the rectum were ulcerated.—Acting Assistant Surgeon J. B. Young.

CASE 630.—Private William J. Davis; age 35; admitted December 2, 1864. Chronic diarrhœa. This man was conscripted about the first of October last, and was attacked with diarrhœa soon after. He deserted about the first of November, and was detained as a prisoner of war. When admitted he was much emaciated and had a peculiar pinched, cadaverous expres-

sion of countenance. His pulse was small and about 140; surface cold; stools involuntary; no appetite; tongue dry and pointed. He was inclined to sleep all the time. Treatment: Tonics, stimulants and opiates. Died, December 5th. *Autopsy* eight hours after death: Both lungs contained tubercles at their apices; the lower lobe of the right lung was hepatized. The heart was dilated and contained a large fibrinous clot in its right side. The mucous membrane of the intestines was congested and softened. The solitary follicles of the small intestine were enlarged. Patches of sloughing were found in the colon and rectum.—Acting Assistant Surgeon J. B. Young.

CASE 631.—Charles S. Jordan, Missouri guerrilla; admitted November 20, 1864. Typhoid pneumonia. Died, December 6th. *Autopsy* twelve hours after death: The lower lobe of the right lung was hepatized. The right auricle of the heart contained clots. The small intestine was inflamed; the solitary glands enlarged. The mucous membrane of the colon and rectum was softened and ulcerated. The mesenteric glands were enlarged.—Acting Assistant Surgeon J. M. Witherwax.

CASE 632.—James M. Clanahan, citizen of Missouri; admitted November 30, 1864. Diarrhœa. Died, December 6th. *Autopsy* sixteen hours after death: Body very little emaciated. The thoracic organs were normal. The liver was normal. The stomach was greatly distended. The solitary glands of the small intestine were enlarged. The large intestine was very much thickened and extensively ulcerated from the cæcum to the rectum. The mesenteric glands were enlarged.—Acting Assistant Surgeon J. E. Brooke.

CASE 633.—Private William A. King, company H, Wood's Missouri guerrillas; age 37; admitted November 29, 1864. Acute diarrhœa. This man was conscripted October 14th and deserted ten days afterward. He had diarrhœa at the time, and it persisted. Was detained as a prisoner of war and sent to Rock Island. When admitted he had ten to twenty copious stools daily; was much emaciated; tongue brown and dry; pulse weak and rather slow; skin dry and husky. He had no appetite, and was inclined to sleep much of the time; when awake seemed moody and dispirited. To take a drachm of sulphate of magnesia with a grain of opium three times a day, and enemata containing acetate of lead. Milk-punch. Died, December 8th. *Autopsy* four hours after death: Some congestion of the abdominal viscera was found, otherwise all the organs appeared to be normal.—Acting Assistant Surgeon J. B. Young.

CASE 634.—John B. Melton, citizen of Missouri; admitted December 4, 1864. Diarrhœa. Died, December 8th. *Autopsy* fifteen minutes after death: Body considerably emaciated. Both lungs were somewhat emphysematous. The pericardium contained twelve ounces of turbid yellowish serum. The heart was rather small, very flaccid, its walls thin, the valves healthy. The liver, spleen and kidneys were normal. The stomach was distended. The mucous coat of the small intestine was congested and the solitary glands enlarged; that of the colon was highly congested and all the coats considerably thickened. The rectum was ulcerated. The mesenteric glands were enlarged.—Acting Assistant Surgeon J. E. Brooke.

CASE 635.—William J. Ferrill, citizen of Missouri; admitted December 1, 1864. Diarrhœa. Died, December 9th. *Autopsy* four hours after death: Body emaciated and jaundiced. Both lungs were hepatized gray; in the right lung several vomicæ were found. The gall-bladder contained three ounces of dark thick bile resembling tar. The mesenteric glands were enlarged. The mucous coat of the rectum was highly congested.—Acting Assistant Surgeon J. M. Witherwax.

CASE 636.—Thomas Cook, a citizen of Missouri; admitted December 8, 1864. Diarrhœa. Died, December 9th. *Autopsy* two hours after death: Body much emaciated. The lungs were normal. The pericardium contained four ounces of straw-colored serum. The liver and spleen were unnaturally firm, the latter five times its normal size; the gall-bladder contained two ounces of black tar-like bile. The mucous membrane of the stomach was slightly congested; that of the duodenum and of a large portion of the small intestine more decidedly so; the solitary glands were enlarged. There was an intussusception in the lower third of the small intestine. The colon was highly congested. The rectum was softened and ulcerated. The mesenteric glands were enlarged.—Acting Assistant Surgeon J. E. Brooke.

CASE 637.—Isaiah H. Jackson; age 72; admitted November 26, 1864. Diarrhœa. This man was taken prisoner October 26th, and soon after was attacked with diarrhœa, which at first was rather dysenteric in character. He improved under treatment after admission until December 5th, when a relapse occurred, the stools became involuntary, and he died December 10th. While in hospital he was restive, dispirited, and seemed to think every one his personal enemy. The treatment was chiefly tonic and stimulant. *Autopsy* twelve hours after death: The thoracic viscera were normal. The mucous membrane of the small intestine was thickened and softened; that of the large intestine extensively ulcerated. The liver and spleen were softened; the kidneys abnormally hard.—Acting Assistant Surgeon J. B. Young.

CASE 638.—Private Charles Urlks, company H, 17th Alabama; admitted December 10, 1864. Chronic diarrhœa and scurvy. Died, December 11th. *Autopsy* twenty-four hours after death: The lungs contained an excess of black pigment. The right auricle of the heart was adherent to the pericardium. The liver was normal; the gall-bladder contained a small calculus. The small intestine was congested. The mucous membrane of the rectum was softened and ulcerated. The inner side of the left leg from the thigh to the ankle was purplish, and on being cut into the tissue beneath the discolored portion appeared to be disorganized.—Acting Assistant Surgeon J. E. Brooke.

CASE 639.—James B. Harman, born in Missouri; age 16; admitted December 7, 1864. Typhoid pneumonia. This lad, who was a deserter from the rebel army, into which he had been conscripted, had long been subject to frequent attacks of fever and ague. He was attacked with diarrhœa about the 19th of November, and on the 4th of December with pain in the left side and cough. When received into the hospital he still had diarrhœa. His tongue was coated with brown fur; pulse 100;

respiration hurried; pain in the left side; anorexia; thirst. The left side was dull on percussion, and on auscultation crepitant and sibilant rales could be heard. Ordered turpentine emulsion and low diet. December 8th: Is worse; the diarrhœa continues. ℞. Dover's powder eighteen grains, bismuth eighteen grains, sulphate of quinia twelve grains; make six powders. Take one every four hours. December 10th: Was delirious last night, and is so yet; vomits bilious matter. Died, December 11th. *Autopsy* twelve hours after death: The upper lobe of the left lung and the lower lobe of the right were hepatized. Pleuritic adhesions existed on both sides. The liver appeared to be normal; the gall-bladder was distended with bile. There was an intussusception in the small intestine. The mucous membrane of the small intestine was congested, the solitary follicles enlarged. The mucous membrane of the rectum was inflamed and softened. The mesenteric glands were enlarged.—Acting Assistant Surgeon H. C. Newkirk.

CASE 640.—Corporal John B. Cason, company E, 3d Florida; age 22; admitted September 20, 1864. Diarrhœa. This man enlisted in the rebel army April 15, 1861. His health previously was good. He was sent to hospital four different times with diarrhœa before being captured at Daysville, Georgia, May 18, 1864. After his capture he was sent to Rock Island prison. He was then suffering with diarrhœa, and was twice transferred from the barracks to the hospital before his final admission, September 20th. Besides the diarrhœa he had scorbutic symptoms, for which citric acid and vegetable diet were administered without effect. He died December 12th. *Autopsy* twenty hours after death: The lower limbs were œdematous and discolored; the gums in a sloughing condition. The mucous membrane of the intestines was congested and ulcerated.—Acting Assistant Surgeon J. B. Young.

CASE 641.—Private Ira G. Cobb, company A, 1st Arkansas cavalry; admitted November 8, 1864. Chronic diarrhœa. December 13th he was transferred to ward M with well-marked erysipelas [of the face?]. Scorbutic patches were observed on his feet and ankles. He died December 14th. *Autopsy* twenty-four hours after death: The large intestine was much ulcerated, particularly the rectum. No other lesions of importance were noted in the other abdominal or thoracic viscera. [The brain was not examined.]—Acting Assistant Surgeon Washington Matthews.

CASE 642.—Private Augustus Allen, company K, 1st Arkansas cavalry; age 36; admitted December 11, 1864. Dysentery. This man stated that he had been sick most of the time for the last year with diarrhœa, bronchitis and pneumonia. When admitted he was extremely feeble and his pulse scarcely perceptible. He had some cough, with scanty expectoration and frequent watery stools. Treatment: Quinine, opium, whiskey, &c. Died, December 16th. *Autopsy* twenty-four hours after death: There were a few tubercles in the right lung, but otherwise the lungs appeared to be normal. The right cavities of the heart contained a fibrinous clot. The intestinal mucous membrane was softened and easily scraped off. The mesenteric glands were enlarged.—Acting Assistant Surgeon H. H. Russell.

CASE 643.—John Allega; age 33; admitted December 6, 1864. Chronic diarrhœa. This man stated that he was conscripted October 25th, by a band of bushwhackers calling themselves "Mountain Hessians," who robbed him of everything, treated him very brutally, and at length turned him loose almost naked and without food. He lay for sixteen days in the mountains almost without food, and during this time was attacked with acute dysentery. He delivered himself up November 8th, and was detained as a prisoner. When admitted to hospital his disease had assumed the character of chronic diarrhœa, and he was greatly emaciated. December 18th, he was attacked with erysipelas of the face, commencing at the nose. Died, December 20th. *Autopsy* six hours after death: There were extensive pleuritic adhesions on the right side, and the left lung was adherent to the diaphragm; the lung-tissue was normal. The colon and rectum were much ulcerated. The other viscera were normal.—Acting Assistant Surgeon Washington Matthews.

CASE 644.—Private George W. Warren, company F, 24th Mississippi; age 24; admitted March 13, 1864. Consumption. This man enlisted in the rebel army in September, 1861. He had measles the winter after enlistment, and was subsequently troubled with cough and diarrhœa. He was hardly ever fit for duty. Was captured November 24, 1863, and committed to Rock Island prison December 5th; next day he was transferred to hospital and found to be suffering from pneumonia. From this he recovered, and was thought well enough to be returned to the barracks March 1, 1864. He, however, again took cold, and was returned to hospital on the 13th with a severe cough and diarrhœa. Was first seen by the reporter December 15, 1864. He was then extremely feeble, had a severe cough, copious expectoration and very troublesome diarrhœa. He had been taking cod-liver oil and milk-punch for some time. Remedies appeared to have but little effect. Died, December 20th, at 2 A. M. *Autopsy* twelve hours after death: Body greatly emaciated. Both lungs contained softened tubercles. The heart was normal; its right auricle contained a large clot. The liver and spleen were congested. The solitary follicles of the small intestine were enlarged. The mucous membrane of the rectum was softened but not ulcerated. The mesenteric glands were enlarged and cheesy.—Acting Assistant Surgeon H. C. Newkirk.

CASE 645.—Private James P. Hampton, of a Missouri regiment; age 18; admitted December 18, 1864. Diarrhœa. This lad enlisted in the rebel army in September, 1864. He had previously enjoyed good health. He was captured in October, and committed to Rock Island prison November 24th. Was taken with diarrhœa about the time of capture, and continued to suffer from it. He took cold December 15th, and had a chill, followed by severe cough and pain in left side, for which he was sent to hospital. When first seen he was dull and listless; his tongue was coated brown; his bowels were loose; pulse 100; respiration hurried; anorexia; thirst. Treatment: Dover's powder, &c., milk-punch, beef-tea. He became delirious, and died December 21st. *Autopsy* twelve hours after death: There were evidences of pleurisy on the left side. The lower lobe of the left lung was congested. There was some effusion of serum into the pericardium. The walls of the heart were thin and flabby. The stomach and intestines were distended with gas. The solitary follicles were ulcerated. The mucous membrane of the rectum was inflamed and softened. The mesenteric glands were enlarged.—Acting Assistant Surgeon H. C. Newkirk.

CASE 646.—Benjamin F. Maddox, a citizen of Missouri; admitted December 8, 1864. Chronic diarrhœa. Died, December 21st. *Autopsy* eight hours after death: The lower lobes of both lungs were congested. The heart was normal. The liver was congested. The spleen was normal. Scarcely a trace of the great omentum remained. The colon and rectum were ulcerated.—Acting Assistant Surgeon Washington Matthews.

CASE 647.—Private James Brady, company B, Love's Missouri regiment; admitted December 19, 1864. Diarrhœa. This man enlisted in October, 1864, and has been suffering with diarrhœa ever since. He was captured during Price's retreat from Missouri, and sent to Rock Island prison, suffering all the while with diarrhœa. When admitted to hospital the diarrhœa was very severe. He was very feeble, and died December 22d. *Autopsy* fourteen hours after death: There was some effusion of serum into the pleural sacs and the pericardium. The lungs contained tubercles. The walls of the heart were very thin. The liver and spleen were nearly normal. The mucous membrane of the small intestine was congested. The colon and rectum were ulcerated. The mesenteric glands were enormously enlarged and filled with a pus-like fluid.—Acting Assistant Surgeon J. B. Young.

CASE 648.—Private James N. Hogan, company G, Gordon's Arkansas regiment; admitted December 17, 1864. Chronic diarrhœa. Died, December 23d. *Autopsy* ten hours after death: The pericardium contained six ounces of serum. The heart, lungs, spleen and liver were normal. The great omentum was completely absorbed. The intestinal mucous membrane was congested, the rectum ulcerated.—Acting Assistant Surgeon Washington Matthews.

CASE 649.—Private George Bridges, company K, 11th Arkansas; age 19; admitted December 12, 1864. Chronic diarrhœa. When admitted this man was emaciated and debilitated to a great degree. He was very irritable in temper, and had evidently suffered much from sickness and exposure. He became unsettled in his mind as his weakness became greater. Was troubled continually with a distressing cough and pain in the chest, which was very severe the night previous to his decease. Died, December 25th. *Autopsy* ten hours after death: The lungs were congested, their lower lobes hepatized. The pleuræ were coated with lymph and pus. The mucous membrane of the large intestine was inflamed and ulcerated.—Acting Assistant Surgeon Washington Matthews.

CASE 650.—Abraham T. McDaniel, Missouri guerilla; age 23; admitted December 19, 1864. Chronic diarrhœa. This man was conscripted by General Price, deserted and surrendered himself to the United States forces. He was sick with diarrhœa from the time he joined Price's army. When admitted to hospital the disease was in an advanced stage; stools involuntary; tongue brown and dry; pulse feeble, frequent and wiry; dyspnœa; anorexia. The treatment consisted of stimulants, tonics and astringents. Died, December 25th. *Autopsy* eight hours after death: Both lungs were filled with tubercles. The pericardium contained a quantity of serum. The liver was normal; the gall-bladder distended with bile. The mesentery was congested, the mesenteric glands enlarged. The mucous membrane of the descending colon and rectum was ulcerated and broken down.—Acting Assistant Surgeon J. B. Young.

CASE 651.—Private J. R. Crow, company I, 36th Alabama; age 35; admitted December 7, 1864. Chronic diarrhœa and consumption. This man had suffered from diarrhœa and cough for several months. When admitted his pulse was small and frequent; tongue dry and brown; skin dry. He died December 26th. *Autopsy* twelve hours after death: Both lungs were full of tubercles, and there were several vomicæ of considerable size; evidences of recent pleurisy were observed on the left side. Large clots were found in both sides of the heart. The mucous membrane of the small intestine was softened; that of the colon and rectum extensively ulcerated.—Acting Assistant Surgeon J. B. Young.

CASE 652.—Private Samuel Ford, company B, 7th Missouri; age 36; admitted December 24, 1864. Chronic diarrhœa. This patient was delirious from the time he came into the ward. He had a dry brown tongue, small frequent pulse, dry skin, &c. Died, December 29th. *Autopsy* six hours after death: The lungs appeared to be nearly normal. The pericardium contained a considerable quantity of serum. The intestinal mucous membrane was in a gangrenous condition. The mesenteric glands were enlarged.—Acting Assistant Surgeon J. B. Young.

CASE 653.—Private Andrew J. Pope, company A, 31st Alabama. Admitted December 13, 1864. Chronic diarrhœa. This patient was an old "hospital soldier." Previous to his last admission to this hospital he had been here under treatment for œdema of the lower extremities and chronic diarrhœa. The former was cured, or greatly relieved, some four or five months ago, while the latter has been unsuccessfully treated in quarters for over six months with various remedies. The patient had, besides, complained at various times of symptoms which seemed to indicate derangement of the kidneys, and has had a cough with expectoration and thoracic pains for about three weeks. He was transferred to ward M late on the evening of December 29th. He complained of feeling very cold, but was able to sit by the fire. He died early on the following morning. *Autopsy* seven hours after death: The pleuræ, pericardium and peritoneum all showed signs of chronic inflammation, and their cavities contained more or less liquid mixed with ropy purulent deposits. Both lungs were hepatized. The large intestine was extensively ulcerated. The medullary substance of the kidneys was much darker and harder than normal.—Acting Assistant Surgeon Washington Matthews.

CASE 654.—Henry Birk, citizen of Virginia; admitted November 21, 1864. Chronic diarrhœa. Died, December 29th. *Autopsy* twelve hours after death: There was recent pleurisy on both sides, and a large quantity of pus adhered to the pleural surfaces. A large abscess was found in the left lung. The mucous membrane of the large intestine was ulcerated. The mesenteric glands were enlarged.—Acting Assistant Surgeon Morris Hale.

CASE 655.—Private Henry Goss, company F, 16th Tennessee; admitted December 12, 1864. Chronic diarrhœa and pneumonia. Died, December 31st. *Autopsy* forty-eight hours after death: The right lung was in the stage of gray hepatization.

The pericardium contained twenty ounces of fluid. The small intestine was inflamed; the large intestine ulcerated, particularly the rectum, which was implicated to an extraordinary degree.—Acting Assistant Surgeon H. C. Newkirk.

CASE 656.—Private Barney Morgan, company F, Freeman's Arkansas regiment; admitted December 27, 1864. Acute bronchitis. Died, January 1, 1865. *Autopsy* twelve hours after death: The right lung was hepatized. The right side of the heart contained clots. The liver was normal; the gall-bladder distended with bile. The spleen very much enlarged. The mucous membrane of the small intestine was congested and colored with bile. The colon and rectum were ulcerated.—Acting Assistant Surgeon H. C. Newkirk.

CASE 657.—Private William Riggins, company F, 3d Georgia cavalry; age 36; admitted November 29, 1864. Scurvy. This man was captured at Knoxville, Tennessee, September 29, 1862; was taken to Louisville, Kentucky, and afterward exchanged at Vicksburg, Mississippi. He was captured a second time on the Holston river, in Tennessee, and sent to Rock Island prison. Has been in hospital twice with diarrhœa, and, in fact, has never been well since arriving at this prison. Since his present admission, except, perhaps, during the first few days, he had no diarrhœa, his bowels being rather constipated. The urine was scanty. He complained a good deal of dyspnœa, and had to be propped up in bed much of the time. His abdomen was very much distended and the intercostal spaces were prominent, apparently from effusion into the abdominal and pleural cavities. He died January 3, 1865. *Autopsy* four hours after death: There was considerable effusion in both pleural sacs; the lungs were full of miliary tubercles. The heart was dilated, its walls thin; the right auricle was so dilated as to hold about four ounces; its walls were as thin as paper. The abdomen was distended with serum; the integument stretched and shiny. The viscera were adherent wherever there was contact; the adhesions consisted of a well-developed fibrous tissue. The mesenteric glands were greatly enlarged, varying from the size of a hazel-nut to that of a hulled walnut. The abdominal viscera thus interadherent formed one solid mass weighing about thirty pounds.—Acting Assistant Surgeon J. B. Young. [No. 651, Medical Section, Army Medical Museum, is from this case. The specimen is a perpendicular section through the abdominal viscera, showing the intestines adherent to each other and the mesenteric glands greatly enlarged, the whole forming a solid mass.]

CASE 658.—Private William C. Millican, company A, 2d Texas cavalry; admitted December 24, 1864. Chronic diarrhœa. Died, January 3, 1865. *Autopsy* six hours after death. The lower and posterior portion of the right lung was hepatized, and some of the bronchial tubes contained pus. The left lung was firmly adherent to the walls of the thorax but was healthy in substance. The spleen was four times the normal size. The ileum was invaginated in three distinct places—the highest implicating ten inches of the intestine, the second two inches and a half, the third three-quarters of an inch. The rectum was extensively ulcerated. The descending colon was also ulcerated, but to a less degree. The mesenteric glands were somewhat enlarged.—Acting Assistant Surgeon Washington Matthews.

CASE 659.—Henry Forrest, citizen; admitted December 15, 1864.—Chronic diarrhœa. Died, January 4, 1865. *Autopsy* eight hours after death: Both lungs were adherent, but otherwise healthy. The pericardium contained a small quantity of fluid. The spleen was unusually pale but of normal size. The mucous coat of the stomach presented indications of chronic inflammation and the muscular coat was thickened. The small intestine was a succession of abnormally large pouches alternating with constrictions. The large intestine was extensively ulcerated. The mesenteric glands were much enlarged. No other abnormal appearances were observed.—Acting Assistant Surgeon Washington Matthews.

CASE 660.—Private Leander T. Wells, company G, 16th Georgia cavalry; admitted December 12, 1864. Chronic diarrhœa. This man when admitted had dysenteric symptoms which in the course of a few days degenerated into diarrhœa, the discharges becoming free and copious but without blood. Died, January 5, 1865. *Autopsy* eight hours after death: The lungs contained a few tubercles and were congested posteriorly. The spleen was not more than a third of its natural size. The ileum was invaginated to the extent of twelve inches. The large intestine was extensively ulcerated, the ulceration increasing in severity as it approached the anus. The other organs were normal.—Acting Assistant Surgeon Washington Matthews.

CASE 661.—Private John Mustin, company D, 2d Arkansas; age 18; admitted December 21, 1864. Diarrhœa and typhoid pneumonia. Died, January 6, 1865. *Autopsy* thirty-six hours after death: Both lungs were extensively hepatized. The bronchial tubes contained muco-pus. There was some effusion into the pleural and pericardial cavities, and clots—thrombi—in both sides of the heart. The liver was enlarged and somewhat congested. Both small and large intestines were ulcerated. The stomach showed some indications of chronic inflammation.—Acting Assistant Surgeon Washington Matthews.

CASE 662.—Private Stephen P. Box, company F, 1st Alabama cavalry; age 36; admitted November 5, 1864. Chronic diarrhœa. This man had suffered with diarrhœa for several months, and had been in hospital for treatment a number of times since he was brought to Rock Island. He was very much emaciated when brought into ward I, and besides severe diarrhœa, had some cough and pain in his chest. These latter symptoms soon subsided; the diarrhœa began to improve; the patient rested well and had a good appetite. He, however, continued to emaciate, and shortly after the first of January, 1865, the diarrhœa became very much worse; he rapidly sank, and died January 8th. *Autopsy* eight hours after death: Both lungs were full of tubercles, which in the left lung had broken down, forming numerous small vomicæ filled with pus; the parenchyma of this lung was so soft as scarcely to allow handling. The mesenteric glands were enlarged. The mucous membrane of the large intestine was softened and ulcerated in large patches.—Acting Assistant Surgeon J. B. Young.

CASE 663.—Private William Judkins, company E, 41st Alabama; admitted October 13, 1864. Chronic diarrhœa and scorbutus. This man was captured at Knoxville, Tennessee, November 1, 1863; arrived at Rock Island January 15, 1864; was soon after sent to hospital suffering with pneumonia and dysentery, from the former of which he recovered; the latter passed into diarrhœa, and he was returned to barracks; growing worse, however, he was sent back to hospital October 13th. At this time he had a dry skin, dry brown tongue, and feeble, frequent pulse. His gums presented evidences of a scorbutic condition. The

evacuations from the bowels were very frequent, and accompanied by tormina and tenesmus. A sustaining treatment was adopted, with citric acid and a chlorate of potash mouth-wash. He died January 9, 1865. *Autopsy* eight hours after death: The lungs contained scattered tubercles; there were pleuritic adhesions on both sides. The pericardium was everywhere firmly adherent to the heart. The mucous membrane of the large intestine was ulcerated. The mesenteric glands were enlarged and disorganized.—Acting Assistant Surgeon J. B. Young.

CASE 664.—Private Andrew Winkles, company D, Wood's Missouri battalion; age 22; admitted December 21, 1864. Chronic diarrhœa. This man enlisted in the rebel army March 15, 1863; soon after he was attacked by diarrhœa, and was sick eight months. He then reported for duty on Sabine river in Arkansas; was captured a few days after and sent to Little Rock, where he was confined in the state prison. Here he was taken sick with dysentery, which continued until he was transferred to Rock Island prison. A few days after his arrival here he was sent to hospital and has ever since been most of his time in hospital, the present being his third admission. He has now the symptoms of advanced chronic diarrhœa; his skin is dry and scaly; he is much emaciated; his tongue red, narrow and tremulous. He died January 13, 1865. *Autopsy* ten hours after death: There was some recent pleurisy with formation of pus on the surface of the right pleura. The left lung and the heart were normal. The mesenteric glands were enlarged. The mucous membrane of the large intestine was thickened and softened. In the colon and rectum there were numerous black warty growths [?] as large as hazel-nuts, which seemed hard, and were so numerous as to almost obliterate the tube.—Acting Assistant Surgeon J. B. Young.

CASE 665.—William Hall, citizen of Missouri; admitted January 13, 1865. Chronic diarrhœa and erysipelas. This man had suffered for a long time before admission with chronic diarrhœa. When admitted he was exceedingly weak, emaciated, and had an erysipelatous swelling of the left leg extending completely to the knee. The cuticle was raised by a number of blisters varying in size from an inch to three and a half inches in diameter; the entire foot and most of the leg were covered by these blisters; the limb was very much swollen, and its surface in many places of a dark-purple color. The patient was delirious and could not be made to take nourishment. Ordered half a grain of sulphate of morphia in two powders, to be taken three hours apart. He remained under the influence of this narcotic nearly all night. January 14th: To take fifteen drops of muriated tincture of iron and four grains of sulphate of quinia three times a day, alternating with a mixture containing tincture of gentian, capsicum and ginger. A solution of acetate of lead to be applied to the leg. During the day the delirium entirely subsided and the patient had some appetite, but he appeared to be losing sensation in the limb, the skin of which was easily abraded, and there exuded a copious discharge of thin, fetid, sanguineous fluid. Applied a solution of nitrate of silver, one scruple to the ounce of water, to the surface of the limb. January 15th: Substituted a solution of bromine for the nitrate of silver. Milk and soup diet. Black and yellow spots have appeared on the diseased limb. The patient is much weaker. He refuses solid food, but will drink milk, soup, &c. Sleeps well and is quite rational. January 16th: The limb is evidently gangrenous, and the patient died at 4.30 P. M. *Autopsy* twenty hours after death: The mucous membrane of the large intestine was much ulcerated. In the small intestine there was an intussusception involving about twelve inches of the intestine. All the other organs were normal.—Acting Assistant Surgeon Washington Matthews.

CASE 666.—Private Richard Roland, company K, 38th Alabama; admitted December 19, 1864. Chronic diarrhœa. This man was a Creek Indian. He had confluent small-pox in the winter of 1863–'4, and has been in poor health ever since. Much of the time he has had diarrhœa and is greatly emaciated. Died, January 20, 1865. *Autopsy* twelve hours after death: Both lungs were filled with miliary tubercles, and there was some effusion in both pleural sacs. The heart was normal. The knuckles of intestine and all the abdominal viscera were firmly bound together by fibrinous adhesions. The liver was unusually pale. [There is no record of the condition of the intestinal mucous membrane.]—Acting Assistant Surgeon J. B. Young.

CASE 667.—Private Samuel Divins, company A, 9th Tennessee cavalry; age 23; admitted December 21, 1864. Chronic diarrhœa. This man when admitted was very much emaciated, and had severe scorbutic symptoms besides diarrhœa. His appetite was poor; his skin scaly; and he could scarcely protrude his tongue, which was narrow and red. Treatment: Citric acid, chlorate of potassa, persulphate of iron and vegetable diet. Died, January 21st. *Autopsy* twelve hours after death: There were very extensive pleuritic adhesions on both sides and both lungs were full of miliary tubercles. All the abdominal viscera were firmly interadherent and the adhesions were thickly studded with tubercles. The intestines themselves were green and rotten.—Acting Assistant Surgeon J. B. Young.

CASE 668.—Private Young C. Rogers, company B, Carlton's Arkansas regiment; age 36; admitted December 24, 1864. Chronic diarrhœa. This man was transferred to Rock Island barracks November 24th, and has had diarrhœa ever since. When admitted, besides the usual symptoms of diarrhœa he had a cough, expectoration, and pain in the left side of the chest; tongue red; pulse 90; appetite tolerably good. ℞. Nitrate of silver two grains, opium and capsicum each six grains; make eight pills. Take one three times a day. Milk diet. January 1, 1865: Add a cough mixture. January 21st: The patient, who up to this time seemed to be doing very well, was suddenly seized with a severe pain in the small of the back. A blister was applied, but the pain became more severe, and he died January 23d. *Autopsy:* Pleuritic adhesions were found on the right side. The gall-bladder was distended with bile. The substance of the kidneys was inflamed [?]. The mucous membrane of the bowels was congested.—Acting Assistant Surgeon H. C. Newkirk.

CASE 669.—Private David A. Gray, Baker's Missouri regiment; admitted January 22, 1865. Dysentery and pneumonia. This man enlisted in the rebel army in September, 1864; deserted in October, and was committed to Rock Island prison in November. His health then was tolerably good. He caught cold January 18, 1865, and was sent to hospital two days after. When admitted he had cough and fever; his tongue was coated and very dry; he had diarrhœa; pulse 100 and very feeble; there was but little expectoration. He complained of soreness in the left breast; on that side there was dulness on percussion, and mucous rale. ℞. Rochelle salt six drachms, opium six grains; make six powders. Take one every four hours. Whiskey

four ounces. Died, January 23d. *Autopsy* twelve hours after death: The lower lobe of the left lung was hepatized and its surface coated with lymph. The liver was congested and soft. The intestinal mucous membrane was congested. The rectum was ulcerated.—Acting Assistant Surgeon H. C. Newkirk.

CASE 670.—Private Richard Sparkman, company B, 10th Kentucky; admitted November 24, 1864. Chronic diarrhœa. At first the following was prescribed: ℞. Sulphate of magnesia one drachm, opium one grain; make four powders. Take one every six hours. Subsequently nitrate of silver and opium were employed, and during the last week of his illness five drops of creasote were given every morning. Stimulants and nutritious food were liberally administered throughout. Died, January 24, 1865. *Autopsy* twelve hours after death: Body much emaciated. The apex of the left lung contained a large number of tubercles, and tubercles were sparingly scattered throughout the remainder of the lung-tissue on both sides; the middle lobe of the right lung was hepatized. The liver was much enlarged. The rectum was extensively ulcerated. No other abnormities were observed.—Acting Assistant Surgeon N. B. Matthews.

CASE 671.—John W. Agan, Missouri conscript; admitted January 20, 1865. Chronic diarrhœa. This patient had frequent purulent stools, accompanied by much griping pain and some tenderness over the abdomen. Prescribed a creasote mixture. January 23d: Seems better. The discharges are somewhat checked. Ordered blue mass and opium pills morning and evening, and during the day the following: ℞. Rhubarb twelve grains, tannic acid twelve grains, opium two grains; make six powders. Take one every three hours. Under this treatment the patient was apparently doing well, but January 25th he died suddenly. *Autopsy:* The lower lobe of the left lung was hepatized. The pericardium contained about ten ounces of fluid. The liver was congested and very dark colored. The spleen was normal. The mesenteric glands were enlarged. In the small intestine there were two intussusceptions, each about eight inches in length. The large intestine was generally congested; the rectum very much ulcerated.—Acting Assistant Surgeon H. F. Salter.

CASE 672.—Private Alfred Driskell, company B, 38th Alabama; age 34; admitted January 9, 1865. Typhoid pneumonia. This man enlisted in the rebel army November, 1862; was troubled a good deal with diarrhœa and cough, so that he was seldom able to do duty. He was captured November, 1863, and sent to Rock Island prison in December. Since then he has been in hospital most of the time with chronic diarrhœa. He had an attack of pneumonia in August, 1864. January 8, 1865, he again caught a severe cold, and was next day once more transferred to hospital. He had at that time a severe cough, fever and pain in the side; his tongue was coated brown in the centre, its margins were red; his pulse was 120; respiration somewhat hurried. He had diarrhœa; but little appetite, and some thirst. He was treated with muriate of ammonia and nitrate of potash, sulphate of cinchona, turpentine emulsion, stimulants, &c. Milk diet. Died, January 26th. *Autopsy* twelve hours after death: Body greatly emaciated. The right lung was hepatized and contained an abscess; there were strong pleuritic adhesions on both sides, and the pleural cavities were partly filled with serum and pus. The liver was congested and softened. The mucous membrane of the intestinal tube was congested; that of the rectum inflamed and softened.—Acting Assistant Surgeon H. C. Newkirk.

CASE 673.—James Suggs, a citizen of Missouri; admitted January 22, 1865. Anasarca. Died, January 28th, of pleuro-pneumonia. *Autopsy* thirteen hours after death: There were pleuritic adhesions on the right side, and the right lung was pneumonified. The left lung was congested and slightly adherent. Both pleural sacs contained serum, in all twenty-four ounces. There was some slight pericarditis. The heart contained clots. The liver was normal. The spleen was enlarged. There were two intussusceptions in the small intestine. The lower part of the ileum was inflamed and ulcerated. The colon and rectum were also ulcerated.—Acting Assistant Surgeon J. E. Brooke.

CASE 674.—Private William K. Sinks, company E, 12th Tennessee cavalry; age 30; admitted October 21, 1864. Chronic diarrhœa. Was transferred to ward I about December 25th, when he was first seen by the reporter. He was then very much emaciated and extremely feeble; his skin was dry and covered with scales; the stools were very frequent. He was constantly crying and fretting about home; nothing that could be done diverted his mind from his family and his apprehension of a fatal result. He gradually sank; the stools became involuntary, and he died January 28, 1865. *Autopsy* four hours after death: Both lungs were full of tubercles, some of which had softened, forming minute vomicæ. The heart was normal. The liver and spleen were somewhat congested. The mucous membrane of the large intestine was thickened, softened and ulcerated in spots. The mesenteric glands were enlarged.—Acting Assistant Surgeon J. B. Young.

CASE 675.—Private Robert Renfrew, company B, 2d Cherokee regiment; admitted January 2, 1865. Chronic diarrhœa and remittent fever. Died, January 30th. *Autopsy* two hours after death: Body extremely emaciated. The thoracic viscera were normal, with the exception of slight pleuritic adhesions on the right side. The liver and spleen were normal. The mesenteric glands were enlarged. The descending colon and rectum were thickened and ulcerated.—Acting Assistant Surgeon J. M. Witherwax.

CASE 676.—Private James Hutchens, company H, Coffin's Missouri regiment; admitted January 6, 1865. Diarrhœa. There is no record of this case, except that the patient had been under treatment for diarrhœa until he was admitted to the erysipelas ward the day of his death. He then seemed very weak, but was able to sit up. He was suffering from dyspnœa and expectorated with difficulty. There was dulness on percussion over the right side of the thorax; his abdomen was tympanitic and tender on pressure; a bluish congested appearance was observed about the occipital region and over the mastoid process, (this continued after death,) and there was a diffused erysipelatous blush over the whole chest. A few hours after his admission to the erysipelas ward he was seized with a paroxysm of dyspnœa, apparently due to a sudden accumulation of mucus in the bronchial tubes, and died in a few minutes, February 1st. *Autopsy* twenty hours after death: The pericardium contained eight ounces of serum. The heart was normal in structure and size; it contained fibrinous clots weighing about three ounces. There

were old pleuritic adhesions on the left side, but the left lung was normal; the right pleural sac contained about two ounces of sero-purulent fluid; the right lung was completely hepatized, coated with recent lymph, and presented at its apex some large tubercles and several cavities filled with pus. The intestines were distended with gas. The colon was congested and the rectum ulcerated, but neither to the great degree so often witnessed. No other abnormities were observed.—Acting Assistant Surgeon Washington Matthews.

Case 677.—James M. Leach, Missouri conscript; age 25; admitted January 27, 1865. Dysentery. This man stated that he was taken sick with a severe cold some time before his admission, and that the cold was followed by dysentery. At the time of admission he had from fifteen to eighteen bloody slimy discharges from the bowels in the twenty-four hours, and severe griping pain in the lower part of the abdomen; he had considerable thirst; his countenance was pale and sallow; he experienced a good deal of pain in urinating; the pulse was 75 and small; the tongue coated yellow; the skin dry and rough. Ordered five grains of blue mass and one of opium, to be taken at once, afterward a mixture containing creasote. Milk diet. January 28th: Treatment continued. January 31st: The symptoms continue unabated. He passes much blood. ℞. Blue mass twenty grains, Dover's powder twenty grains; make four pills. Take one every four hours. Enemata of acetate of lead and laudanum. February 1st: Continue treatment. Died, February 2d. *Autopsy* the same day: The pericardium contained eight ounces of serum. The left lung was hepatized. The liver was healthy; the gall-bladder distended with bile. The spleen was larger than normal. The mesenteric glands were much enlarged. There were two intussusceptions in the small intestine. The rectum was much ulcerated.—Acting Assistant Surgeon H. F. Salter.

Case 678.—Alfred Gagen, a citizen of Missouri; admitted January 3, 1865. Chronic diarrhœa. There is no record of the history of this patient until January 30th, when he was transferred to the erysipelas ward. He was then much emaciated; his voice was weak. He had a slight erysipelatous inflammation under the left eye; the pulse was feeble; the stools frequent and copious. There was some dulness on percussion over the lower part of the right lung posteriorly, and considerable dulness over the entire left lung. On succussion a splashing sound was heard at the third intercostal space. He was treated with stimulants and a blister was applied to the left side of the chest. February 4th: He woke up feeling better, but, after conversing in a lively manner for a few moments, lay quietly back and died without a struggle. *Autopsy* four hours after death: The pericardium contained six ounces of sero-purulent matter. The right pleural sac contained two quarts of a similar fluid. There was a clot, an ounce in weight, in the right auricle extending into the ventricle. A limited portion of the base of the right lung was hepatized. The rectum was ulcerated. No other abnormities were observed.—Acting Assistant Surgeon Washington Matthews.

Case 679.—William S. Clay; age 29; admitted February 1, 1865. Acute diarrhœa. This man was first taken sick with a severe cold, and diarrhœa followed. He had from ten to twelve passages daily, with severe tormina. The stools consisted of blood and slime. When admitted his countenance was shrunken and pale; tongue dry and coated with a yellow fur; skin soft; pulse 75. He had considerable thirst but no appetite. He was also troubled with a constant cough and pain in the chest. ℞. Rhubarb six grains, tannin nine grains, opium two grains; make three powders. Take one every three hours. A sinapism to the abdomen. Milk diet. February 2d: Continue treatment, with ten grains of Dover's powder at night. February 3d: Milk-punch. February 4th: The patient is no better. He complains also of a dull heavy pain in the chest. There is dulness on percussion below the nipple on both sides. ℞. Blue pill twenty grains, acetate of lead twelve grains, opium two grains; make four pills. Take one every three hours. Died, February 6th. *Autopsy* the same day: Both auricles of the heart contained fibrinous clots. Both lungs were hepatized. The liver and spleen were healthy. The mucous membrane of the small intestine was congested; that of the large intestine congested and extensively ulcerated. The mesenteric glands were very large.—Acting Assistant Surgeon H. F. Salter.

Case 680.—Private S. Terrill, company D, 4th Alabama cavalry; admitted January 13, 1865. Chronic diarrhœa. When seen next day the patient was much debilitated, had no appetite, and, besides a profuse diarrhœa, complained of a painful swelling of the right cervical lymphatic glands. Ordered tincture of iodine to be applied to the swelling twice daily and the following: ℞. Tannic acid twelve grains, opium and camphor of each three grains; make six powders. Take one every four hours. This treatment was continued for the next week. January 21st: His appetite and general condition is improving, but the swelling has increased. The iodine was discontinued and a flaxseed poultice applied. January 22d: Complains of loss of sleep. Stopped the former powders, and ordered three grains of Dover's powder to be taken every three hours. This was continued until January 30th. February 1st: Substituted the following: ℞. Sulphate of quinia twelve grains, Dover's powder fifteen grains; make three powders. Take one every four hours. This was continued until February 5th, when the abscess was opened, discharging copiously. The wound was washed twice daily and a simple dressing applied. February 8th: Facial erysipelas made its appearance, for which tincture of iodine was applied, and twenty drops of the tincture of the chloride of iron given internally three times daily. The erysipelas subsided, but the integument about the orifice of the abscess of the neck speedily sloughed, forming a phagedenic ulcer of considerable size. Meanwhile the diarrhœa grew constantly worse; the pulse became rapid and feeble; sordes collected on the teeth and lips; and the patient died February 17th. *Autopsy* seven hours after death: Body much emaciated. The ulcer on the right side of the neck had extended until it was about four inches and a half in diameter, laid bare the muscles of the neck, dissected between them, and nearly communicated with the pleural cavity of the right side, as was shown by the fact that a dark stain, caused by an application of persulphate of iron shortly before death, had penetrated to the apex of the right lung, which was strongly adherent. The second and third portions of the subclavian artery and part of its first portion were quite denuded of the surrounding tissue. An old fracture of the right clavicle was also observed. The pericardium contained four ounces of fluid. There was an intussusception in the ileum. The descending colon and rectum were ulcerated. The mesenteric glands were enlarged. No other abnormities were observed.—Acting Assistant Surgeon Washington Matthews.

CASE 681.—Thomas Monahan, a citizen of Missouri; admitted January 7, 1865. Diarrhœa. While under treatment this man had a slight attack of facial erysipelas, which, however, only involved a patch of about three inches in diameter. Subsequently he complained of a swelling in his left knee, which on examination proved to be a small abscess. This was opened February 15th, and discharged two ounces of bloody pus. The abscess was surrounded by ten small but unhealthy-looking ulcers. Scorbutic stains were observed on both lower extremities. The patient now had rigors and febrile paroxysms daily, and died February 18th. *Autopsy* eight hours after death: Body much emaciated. The brain-substance was soft, but otherwise perfectly normal. There were old pleuritic adhesions on the right side. The left pleural cavity contained twelve ounces of serum. The lower lobe of the left lung was hepatized. The pericardium contained a pint of fluid. There was more or less congestion of the whole intestinal mucous membrane, and some ulceration of the rectum. The other abdominal organs appeared to be healthy.—Acting Assistant Surgeon Washington Matthews.

CASE 682.—George Hill, Missouri volunteer; admitted December 6, 1864. Chronic dysentery. Died, March 6, 1865. *Autopsy* two hours after death: Body much emaciated. The thoracic viscera were normal. Nothing abnormal was observed in the liver, spleen or stomach. The mucous membrane of the ileum was inflamed; that of the cæcum and lower part of the colon was inflamed and softened. The rectum was gangrenous. The mesenteric glands were enlarged.—Acting Assistant Surgeon J. M. Witherwax.

The next two cases were forwarded, with the specimens, from the HARVEY HOSPITAL, Madison, Wisconsin, Surgeon Howard Culbertson, U. S. V., in charge:

CASE 683.—Private Charles Collier, company A, 8th Wisconsin volunteers; admitted March 18, 1864. Chronic diarrhœa. [This man appears on the hospital register of his regiment, then at Oxford, Mississippi, admitted December 15, 1862—catarrh—returned to duty January 17, 1863. He again appears on the hospital register of the regiment, then at Big Black, Mississippi, admitted September 14th—dropsy—sent to general hospital October 10th. He is borne on the register of hospital No. 1, Vicksburg, Mississippi, admitted October 10th—rheumatism—transferred to the Invalid Corps October 21st; and on the register of hospital No. 2, Vicksburg, admitted October 26th—chronic dysentery.] Died, July 15th, after an attack resembling ileus, which lasted thirty-six hours. The symptoms were great pain, obstinate vomiting, early prostration, constipation, and great distention of the abdomen by flatus. The treatment consisted in the use of anodynes.—Surgeon Howard Culbertson, U. S. V. [No. 505, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the mesentery in which an opening has been formed through which several feet of the lower part of the ileum passed and subsequently became strangulated. When received at the Museum the cavity of the strangulated intestine was found to be full of clotted blood. The laminæ of the portion of mesentery belonging to the strangulated intestine were separated by hemorrhagic extravasation, and the whole peritoneal surface of the intestine was dark from the engorged condition of the vessels.]

CASE 684.—Private Uri Probst, company F, 25th Wisconsin volunteers; age 45; admitted July 12, 1864. Chronic rheumatism. [This man appears on the register of hospital No. 1, Nashville, Tennessee, admitted June 13th, from Chattanooga—inflammatory rheumatism—sent to Louisville June 16th. He appears on the register of Jefferson hospital, Jeffersonville, Indiana, admitted June 16th—chronic rheumatism—sent to St. Louis June 29th. He appears on the register of Jefferson Barracks, St. Louis, Missouri, admitted July 5th, from hospital steamer J. F. Ford—chronic rheumatism—sent to Madison, Wisconsin, July 12th.] Died, August 1st, of inflammation of the bowels.—Surgeon Howard Culbertson, U. S. V. [No. 495, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the transverse colon, which is thickened, softened, and presents numerous excavating ulcers which penetrate to the muscular coat.]

The notes of the next case were forwarded, with the specimen, from the POST HOSPITAL, Rolla, Missouri, Surgeon Howard Culbertson, U. S. V., in charge:

CASE 685.—Private August Mere, company A, 9th Missouri cavalry; admitted November 11, 1862. Chronic diarrhœa. Had been sick for the last six months. Treatment: Anodynes, astringents, alteratives and tonics. Died, February 1, 1863. *Autopsy:* The mucous membrane of the entire colon and rectum was thickened and ulcerated; at points the muscular coat was penetrated.—Surgeon Howard Culbertson, U. S. V. [No. 184, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the descending colon, the mucous membrane of which is thickened, plastered with pseudomembrane, and presents a number of irregular ulcers.]

The next two cases are from the case-book of LAWSON HOSPITAL, St. Louis, Missouri, Surgeon C. T. Alexander, U. S. A., in charge:

CASE 686.—Private George Stoute, company D, 67th Indiana volunteers; age 34; admitted from hospital steamer City of Memphis February 22, 1863. Diarrhœa. This man had been sick since September 17, 1862, when he had an attack of intermittent fever. Died, March 16th. *Autopsy:* The rectum was very much ulcerated, and there was an intussusception in the small intestine, which, however, produced no symptoms during life.

CASE 687.—Private Leander Martin, company C, 31st Missouri volunteers; admitted, per hospital steamer D. A. January, from hospital steamer Nashville, Milliken's Bend, Louisiana, March 21, 1863. Diarrhœa. The patient stated that he had been sick two months. He was much emaciated, his tongue coated brown, and he complained a great deal of nausea. Lime-water and milk seemed to be the most efficacious remedy for the latter trouble, but for several days after admission his stomach would tolerate no solid food. Toward the close of the month of March his stomach became less irritable, but the diarrhœa continued;

he became low spirited, and finally sank into a typhoid condition. April 6th: He had a distinct chill, and afterward grew rapidly worse, and died April 8th. *Autopsy:* No lesion of importance was discovered except in the large intestine, the mucous membrane of which was very much congested, thickened, and presented a number of minute ulcers.

The next twenty cases were forwarded on medical descriptive lists from the CITY HOSPITAL, St. Louis, Missouri, Surgeon John T. Hodgen, U. S. V., in charge:

CASE 688.—Private William L. Brigandini, company A, 32d Missouri volunteers; age 31; admitted, per hospital steamer City of Memphis, from Milliken's Bend, Louisiana, May 10, 1863. Chronic diarrhœa. The patient was feeble, emaciated, and had from four to six stools daily. Treatment: Stimulants and astringents. Died, May 14th. *Autopsy:* There were old pleuritic adhesions on the right side and an unusual amount of fat on the surface of the heart. The mucous membrane of the ileum was thickened, softened and congested; that of the colon was thickened, softened and ulcerated. The kidneys were enlarged and granular; the two weighed seventeen ounces.—Acting Assistant Surgeon Stephen R. Gay.

CASE 689.—Private William McDowell, company I, 56th Ohio volunteers; age 27; admitted from Milliken's Bend, Louisiana, per hospital steamer City of Memphis, May 10, 1863. Chronic diarrhœa. The patient suffered also from a bronchial complication, for which syrup of squill and morphia were used occasionally; the general treatment consisted in the free use of infusion of helianthemum, and the following powders three times daily or as required. ℞. Aromatic powder two scruples, bismuth one drachm, tannic acid one scruple, Dover's powder half a drachm; make twenty powders. Diet: Bread and milk, soup, wine. May 12th: Substituted a turpentine emulsion containing morphia for the powders. Died, May 14th. *Autopsy:* Body greatly emaciated. The heart was enlarged and fatty. The lungs were emphysematous. The mucous membrane of the ileum was congested; that of the large intestine was softened. The kidneys were large and soft.—Acting Assistant Surgeon Wm. A. McMurray.

CASE 690.—Private Reuben Winser, company F, 32d Missouri volunteers; age 24; admitted from Milliken's Bend, Louisiana, per hospital steamer City of Memphis, May 14, 1863. Chronic diarrhœa. The patient was moribund when admitted, much emaciated, and unable to articulate. Died, May 15th. *Autopsy:* There were old pleuritic adhesions on both sides and tubercles in the right lung. The mucous membrane of the large intestine was much softened. The kidneys were enlarged and softened.—Acting Assistant Surgeon Wm. A. McMurray.

CASE 691.—Private W. E. Shameer, company K, 30th Missouri volunteers; age 25; admitted May 14, 1863. Chronic diarrhœa. The patient was much emaciated, and died next day. *Autopsy:* There were some pleuritic adhesions. The ileum and large intestine were ulcerated. The kidneys were large.—Acting Assistant Surgeon Wm. A. McMurray.

CASE 692.—Private Gottlieb Wittler, company G, 83d Indiana volunteers; age 35; admitted May 14, 1863. Chronic diarrhœa. Treatment: Nitrate of silver pills; whiskey. Died, May 16th. *Autopsy:* The right lung presented evidences of lobular pneumonia. The liver was soft and fatty. The ileum was intensely congested, and the mucous membrane of the colon was softened. The right kidney was also softened.—Acting Assistant Surgeon Stephen R. Gay.

CASE 693.—Private Morris Chaplin, company E, 99th Illinois volunteers; age 34; admitted from Milliken's Bend, Louisiana, per hospital steamer City of Memphis, May 10, 1863. Chronic diarrhœa. Was taken ill at Helena, Arkansas, April 5th. When admitted the patient was very weak; his tongue dry and coated; appetite poor; pulse 90 and feeble. He had twelve to fourteen stools a day. To take powders containing a grain each of acetate of lead and opium twice daily, and a teaspoonful of tincture of arnica three times a day. Died, May 16th. *Autopsy:* There were pleuritic adhesions at the apex of the right lung and miliary tubercles in its upper lobe; in the middle lobe of the same lung there was a tubercle as large as a filbert. The mucous membrane of the whole large intestine was thickened and softened; in the descending colon and rectum it was ulcerated. The left kidney contained a cyst holding about a drachm of fluid.—Acting Assistant Surgeon Oscar Blank.

CASE 694.—Private J. W. Thompson, company D, 3d Illinois cavalry; age 23; admitted from Milliken's Bend, Louisiana, per hospital steamer City of Memphis, May 10, 1863. Chronic diarrhœa. Was taken ill January 15th, at Vicksburg, Mississippi. When admitted he was very feeble; had no appetite; the stools were frequent and fluid. He had cough and purulent sputa. Treatment: Acetate of lead and opium; special diet; wine. Died, May 16th. *Autopsy:* There were old pleuritic adhesions on the right side. The pericardium contained four ounces of serum. The heart was normal. The mucous membrane of the colon was thickened and softened.—Acting Assistant Surgeon Oscar Blank.

CASE 695.—Private M. Hole, company F, 20th Ohio volunteers; admitted from Milliken's Bend, Louisiana, per hospital steamer City of Memphis, May 10, 1863. Diarrhœa. When admitted he complained of severe pain in the abdomen and had frequent stools. Treatment: Astringents, stimulants, half diet. Died, May 17th. *Autopsy:* There were recent pleuritic adhesions on both sides. The lower lobe of the right lung was much congested. The mucous membrane of the colon was inflamed and ulcerated.—Acting Assistant Surgeon J. C. Shattuck.

CASE 696.—Private Michael McElroy, company B, 32d Missouri volunteers; age 45; admitted from Milliken's Bend, Louisiana, per hospital steamer City of Memphis, May 10, 1863. Chronic diarrhœa. The patient had typhoid symptoms and anasarca. Ordered him to drink infusion of helianthemum. Diet: Milk, soup, toddy, &c. May 13th: Turpentine emulsion containing morphia. The diarrhœa, however, continued; bilious vomiting set in, and he died May 17th. *Autopsy:* the liver was fatty. The mucous membrane of the large intestine was softened and ulcerated. The kidneys were softened.—Acting Assistant Surgeon Wm. A. McMurray.

CASE 697.—Private Frederick Miller, company C, 58th Ohio volunteers; age 36; admitted from Milliken's Bend, Louisiana, per hospital steamer City of Memphis, May 10, 1863. Chronic diarrhœa. The patient was very much emaciated. Ordered infusion of helianthemum, and powders containing tannic acid and Dover's powder; stimulants were also used freely; milk diet. The patient had a ravenous appetite and tried all means to indulge it. Died, May 17th. *Autopsy:* There were old pericardial adhesions, but the heart was normal. The right pleural sac contained a large quantity of serum. There were patches of ecchymosis in the duodenum and the upper part of the jejunum, and small circumscribed ulcers with raised edges in the lower part of the colon. A supernumerary spleen, about as large as a filbert, was found attached to the great omentum near the left end of the stomach. Both kidneys were congested and granular, the left being more diseased than the right.—Acting Assistant Surgeon Wm. A. McMurray.

CASE 698.—Private E. L. Brown, company B, 108th Illinois volunteers; age 25; admitted from hospital steamer City of Memphis May 10, 1863. Chronic diarrhœa. This man was taken ill in January, at Arkansas post, Arkansas. When admitted he was very weak, his appetite poor, bowels very loose. Astringents and tonics were prescribed, with special diet and wine. Died, May 18th. *Autopsy:* There were pleuritic adhesions on both sides, and the right lung was hepatized. The mucous membrane of the ileum was congested, thickened and softened; that of the large intestine was softened and slightly ulcerated. The kidneys were also softened.—Acting Assistant Surgeon Oscar Blank.

CASE 699.—Private J. Hepler, company H, 60th Indiana volunteers; age 40; admitted per hospital steamer City of Memphis May 10, 1863. Diarrhœa and hemorrhoids. This man was taken ill with diarrhœa in January, at Memphis, Tennessee. When admitted, besides his diarrhœa he was much troubled with hemorrhoids and was very feeble. Treatment: Tonics and astringents; half diet; subsequently whiskey as a stimulant. Died, May 19th. *Autopsy:* The liver was softened and fatty. The mucous membrane of the ileum was congested and softened. The kidneys were also softened and congested. [There is no record of the condition of the large intestine.]—Acting Assistant Surgeon Stephen R. Gay.

CASE 700.—Sergeant Henry McKnew, company B, 30th Missouri volunteers; age 26; admitted May 14, 1863. Chronic diarrhœa. The patient was much emaciated and complained of severe abdominal pain. To take three times daily a pill containing quarter of a grain of nitrate of silver and a grain each of rhubarb and opium. Milk-punch and beef-tea. The abdominal pains disappeared, but the diarrhœa continued. Died, May 21st. *Autopsy:* There were old pleuritic adhesions on the left side. The mucous membrane of the ileum and colon was ulcerated. The kidneys were soft and granular.—Acting Assistant Surgeon Stephen R. Gay.

CASE 701.—Private William Hunt, company A, 54th Indiana volunteers; age 28; admitted from hospital steamer City of Memphis May 10, 1863. Diarrhœa and bronchitis. Treatment: Expectorants and tonics; full diet. May 13th: The cough is improving, but the diarrhœa grows worse. ℞. Nitrate of silver two grains, powdered opium eight grains, powdered rhubarb eight grains; make eight pills. Take one every three hours. Milk-punch and beef-tea. May 14th: Complains of some abdominal pain and tenderness. May 15th: The abdominal soreness is increasing. Continue treatment. Died, May 22d. *Autopsy:* The mucous membrane of the ileum and colon was much softened. The kidneys were soft and granular.—Acting Assistant Surgeon Stephen R. Gay.

CASE 702.—Corporal H. F. Graham, company B, 118th Illinois volunteers; admitted from hospital steamer City of Memphis April 8, 1863. Chronic diarrhœa and anasarca. Was taken sick in November, 1862, at Memphis, Tennessee. Treatment: Astringents and opiates. Died, May 22d. *Autopsy:* The mitral valve was thickened and contracted. The two kidneys weighed about eighteen ounces and a half. [There is no record of the condition of the intestinal canal.]

CASE 703.—Private Lewis Warren, company G, 10th Missouri volunteers; age 20; admitted from hospital steamer City of Memphis April 25, 1863. Chronic diarrhœa. Was taken sick at Vicksburg, Mississippi, in November, 1862. He continued to get worse and worse, and reached this place a skeleton. Infusion of helianthemum was prescribed, and the following: ℞. Tannic acid one scruple, Dover's powder half a drachm, subnitrate of bismuth one drachm, aromatic powder two scruples; make twenty powders. Take one every three hours. April 28th: Substituted an emulsion of turpentine containing morphia. For diet, thickened milk and crackers; blackberry cordial, wine and toddy as stimulants. Died, May 23d. *Autopsy:* There were old pleuritic adhesions on both sides and tubercles in both lungs. The colon was ulcerated. The mesenteric glands were enlarged. The kidneys were soft and granular, and there were some tubercles in the left kidney.—Acting Assistant Surgeon Wm. A. McMurray.

CASE 704.—Private H. J. Edington, company I, 96th Ohio volunteers; age 22; admitted from hospital steamer City of Memphis May 10, 1863. Quotidian intermittent fever and chronic diarrhœa. The patient was extremely nervous and could not lie still. Treatment: Quinine and morphia; full diet. May 12th: Is quieter. Treatment continued. May 13th: The diarrhœa is profuse, and he complains of severe pain in the abdomen. Quinine and astringents; half diet. May 15th: No improvement. The pain in the abdomen is increasing; the stools are small and mucous. To take pills of nitrate of silver and opium, beef-tea, milk-punch. Died, May 23d. *Autopsy:* There were old pleuritic adhesions on both sides, and fifty-four ounces of purulent serum in the right side of the chest. The mucous membrane of the colon was softened and ulcerated. The kidneys were soft and granular. The urine was albuminous.—Acting Assistant Surgeon Stephen R. Gay.

CASE 705.—Private Elias Jacobs, company D, 31st Iowa volunteers; admitted April 25, 1863. Chronic diarrhœa. Was taken sick at Helena, Arkansas. Treatment: Astringents and half diet. Died, May 28th. *Autopsy:* There was lobular pneumonia of both lungs, and pleuritic adhesions on both sides. The liver was fatty. The mucous membrane of the ileum and colon was softened and ulcerated. The kidneys were soft and granular.

CASE 706.—William B. Stowe, quartermaster's clerk, admitted May 14, 1863. Chronic diarrhœa of five months' standing. He was treated with astringents, opiates and stimulants, and at first with good effect. May 17th: He had but one passage, which was of natural consistence. May 20th: The diarrhœa recurred, and continued until death. Died, May 31st. *Autopsy:* There were pleuritic adhesions on the left side. The mucous membrane of the ileum and colon was congested, softened and ulcerated.—Acting Assistant Surgeon William H. D. Noyes.

CASE 707.—Private S. Brown, company E, 31st Iowa volunteers; age 44; admitted from hospital steamer City of Memphis May 10, 1863. Chronic diarrhœa. This man was taken sick in November, 1862, at Helena, Arkansas. After admission to this hospital he was treated with opium, astringents and stimulants. Died, June 7th. *Autopsy:* There was a deposit of tubercles in the upper lobe of the right lung. The mucous membrane of the ileum and colon was softened and much ulcerated. The kidneys were softened and congested.

The next case was forwarded on a medical descriptive list from HOSPITAL No. 4, Louisville, Kentucky, Acting Assistant Surgeon John E. Crowe, in charge:

CASE 708.—Private Henry Sluder, company I, 24th Indiana battery; age 33; admitted August 20, 1863. Chronic diarrhœa. When admitted the patient was very weak and much emaciated; pulse 100. He had about ten or twelve evacuations daily. He stated that he had been suffering with diarrhœa for about four months. Has performed no duty for two months. ℞. Powdered opium six grains, tannin ten grains; make six powders. Take one every three hours. Whiskey every two hours; milk diet. August 21st: Had ten evacuations during last night. Treatment continued, with the addition of beef-tea. August 22d: Substitute the following: ℞. Subnitrate of bismuth half a drachm, powdered opium eight grains; make eight powders. Take one every three hours. August 25th: Condition continues without much change; pulse 95. Substitute opium, in grain doses every three or four hours, for the former medicine. August 29th: Sinking. Pulse feeble and over 100. Died during the morning. *Autopsy* six hours after death: The lungs, heart, liver and stomach were healthy. The small intestine was healthy to about fourteen or sixteen inches above the ileo-cæcal valve, below which point the mucous membrane of the ileum was inflamed. The whole course of the large intestine from the cæcum to the anus was honey-combed with ulcers, the ulceration being most extensive in the ascending colon, where almost the whole of the mucous membrane of the bowel was destroyed. About twelve inches above the ileo-cæcal valve there was a diverticulum of the ileum about two inches long and of nearly the same diameter as the ileum.—Acting Assistant Surgeon Abram V. Brewer.

The next two cases were forwarded on medical descriptive lists from HOSPITAL No. 9, Louisville, Kentucky, Surgeon Frank Meacham, U. S. V., in charge:

CASE 709.—Private Gibson Snodgrass, company D, 18th Kentucky volunteers; age 34; admitted May 11, 1863. Chronic diarrhœa. From the statement of the patient it appears that he contracted diarrhœa while in camp near Murfreesborough; it assumed the dysenteric form, and he had free discharges of blood and mucus. When admitted he was much emaciated, but the diarrhœa was not frequent or severe, and for some two weeks he improved slowly. About this time, owing to some imprudence in diet, he grew suddenly worse. The diarrhœa returned with great severity and he was rapidly prostrated. The dejections became thin and yellowish, but not mixed with either blood or mucus. He was treated with pills of nitrate of silver and opium, citrate of iron and quinia; rubefacients to the abdomen, milk-punch and other stimulants; a nourishing diet, &c. June 4th: Bilious vomiting set in, accompanied by tormina and tenesmus. Died, June 7th. *Autopsy* four hours after death: Rigor mortis strongly marked; emaciation extreme. The brain and its membranes were healthy. There were old pleuritic adhesions on the right side, and recent ones on the left side between the lung and the diaphragm. A few tubercles were scattered through both lungs, most abundantly in the upper lobes; some of them were cretefied. The heart and pericardium were normal. The liver was also normal; the gall-bladder was full of fluid bile. The stomach was contracted, and contained a little bile mixed with mucus. The spleen was small but healthy. The mesenteric glands were greatly enlarged. The kidneys and suprarenal capsules were normal. In the small intestine both the solitary glands and the glands of Peyer were enlarged and ulcerated. The large intestine was ulcerated throughout its whole extent.—Acting Assistant Surgeon David W. Flora.

CASE 710.—Private George Halinger, company K, 2d Missouri volunteers; age 47; admitted June 24, 1863. Acute dysentery. [This man appears on the register of hospital No. 20, Nashville, Tennessee, admitted June 20th—dysentery—sent to general hospital June 24th.] He said he had been sick about ten days or two weeks. His countenance was extremely anxious, features pinched; pulse 100 and feeble; tongue coated brown; abdomen tender over the transverse and descending colon, particularly at the sigmoid flexure; stools frequent and largely mixed with blood. There was tormina, tenesmus and prolapsed rectum. June 25th: ℞. Dover's powder twenty grains, sulphate of morphia four grains; make five powders. Take one every four hours. Toast, tea, boiled milk. June 23th: The stools are bloody and frequent; tongue becoming lighter colored; pulse feeble and compressible. There is nausea and intense thirst. ℞. Sulphate of morphine five grains, persulphate of iron ten grains, powdered cinnamon twenty grains; make five powders. Give one once or twice a day. A mustard plaster to the stomach; an ounce of wine three times a day. Diet as before. June 27th: Is much worse; hiccough has set in. The skin is cold and clammy; the stools bloody and somewhat purulent. Continue treatment. An ounce of wine every three hours. Died, June 28th. *Autopsy* twelve hours after death: Rigor mortis strongly marked; body but little emaciated. There was considerable effusion of serum beneath the arachnoid, and the surface of the brain was much congested; on removing the brain an ounce of serum was found at the base of the skull. The lungs were normal; extensive adhesions were found at the apex of the right lung, and between its lower lobe and the diaphragm. The heart was normal. The liver was healthy, except some old adhesions with the diaphragm opposite the pleural adhesions above mentioned; the gall-bladder was full of bile. The

stomach contained seven ounces of fluid; its mucous surface was slightly congested in patches. The spleen was rather small. The pancreas was unusually large but healthy. The kidneys presented nothing abnormal. The duodenum and jejunum were slightly congested, and contained a good deal of bilious matter. The ileum was thickened and softened, especially near the ileo-cæcal valve. The cæcum was intensely inflamed; and the whole tract of the colon and rectum was congested, thickened and softened, and ulcerated in patches. The bladder was empty.—Acting Assistant Surgeon David W. Flora.

The note of the following case was forwarded, with the specimen, from TAYLOR HOSPITAL, Louisville, Kentucky, Assistant Surgeon William T. Okie, U. S. A., in charge:

CASE 711.—Private Hanson Sherwood, company C, 1st Michigan cavalry; admitted February 4, 1864. Chronic diarrhœa. On the morning of the 22d he was suddenly seized with dyspnœa, and died at 4 P. M. the same day. The epiglottis was scarified a few minutes prior to death, and preparations for laryngotomy were being made when he expired. *Autopsy:* There was well-marked œdema of the epiglottis. [The condition of the abdominal viscera is not recorded.]—Assistant Surgeon William T. Okie, U. S. A. [No. 302, Medical Section, Army Medical Museum, is from this case. The specimen consists of the larynx and trachea, laid open from behind, and exhibiting considerable œdema of the epiglottis. The mucous membrane of the larynx and trachea is apparently healthy.]

The next sixty-three cases are from the case-book of HOSPITAL No. 1, Nashville, Tennessee, with the exception of the first case in the series, which was forwarded on a medical descriptive list, Surgeon Caleb W. Horner, U. S. V., in charge:

CASE 712.—Private Daniel Haviland, company G, 10th Michigan volunteers; age 35; admitted August 10, 1863. Dysentery. The patient states that he was taken with a chill July 1st—on the following day dysentery commenced. He is now greatly emaciated, exceedingly weak, and has from six to eight evacuations daily; the discharges are whitish and mixed with blood. He has pain in the iliac region, and tenesmus; pulse 70 and small; tongue moist, with a white fur in the centre; appetite good. Gave an ounce of castor oil with twenty drops of laudanum, to be followed by pills of opium and acetate of lead every four hours; six ounces of milk-punch daily; opium suppositories; milk diet. August 15th: Is improving. The number of discharges has been reduced to three or four daily, but are otherwise the same; the tenesmus is much diminished. The pills of opium and acetate of lead to be continued; four ounces of wine daily instead of the punch. August 20th: The patient commenced to vomit this morning, ejecting a greenish fluid. Ordered a third of a grain of sulphate of morphia every four hours. Continue the wine. August 23d: The vomiting still continues; pulse 100 and very small. Died during the day. *Autopsy* eighteen hours after death: Body greatly emaciated. The lower lobes of both lungs were emphysematous, while the upper lobes were congested. The heart was small and flabby. The ascending and transverse colon were studded with large deep ulcerations. Parts of the small intestine were highly injected, and an abrasion of the mucous membrane was noticed in several parts of the ileum. The mesenteric glands were enlarged and of a purple color. The spleen was slightly enlarged, but apparently healthy. The kidneys were healthy. The liver was of normal size and color, but there was a large abscess about two inches in diameter, containing about four ounces of laudable pus, in the superior anterior part of the right lobe.—Assistant Surgeon Charles J. Kipp, U. S. V.

CASE 713.—Private William H. Gorman, company B, 69th Ohio volunteers; age 25; admitted October 17, 1863. Anæmia. Died, October 25th. *Autopsy* thirty-four hours after death: Body greatly emaciated. Brain not examined. There were recent pleuritic adhesions on the right side. The lower lobe of the right lung was congested and contained one hard tubercle; there was also some slight congestion of the lower lobe of the left lung. The heart was small and contained a small post mortem clot in the right side. The mesenteric glands were very much enlarged. The mucous membrane of the ileum was inflamed and slightly abraded. The large intestine was extensively ulcerated. The liver, spleen and kidneys were normal.

CASE 714.—Private John Evans, company D, 6th Kentucky cavalry; age 43; admitted from the field hospital of the army of the Cumberland, Stevenson, Alabama, October 12, 1863. Chronic diarrhœa. Died, October 29th. *Autopsy* twenty-four hours after death: Brain not examined. The whole surface of the right lung was coated with pus-like lymph; the upper lobe of the right lung was hepatized gray, the lower lobe was engorged with blood; the lower lobe of the left lung was hepatized red. The pericardium and heart were normal. The left lobe of the liver was somewhat fatty. The spleen was normal. The cortical portion of the kidneys was enlarged. The bladder was distended with urine. The mesenteric glands were very much enlarged. The mucous membrane of the stomach presented a small patch of inflammation; that of the intestines was inflamed throughout, and presented a few small ulcers with numerous small isolated deposits which were hard to the touch, and when cut into exuded a bloody fluid. [Enlarged solitary follicles?]

CASE 715.—Private Archibald C. Winders, company A, 81st Indiana volunteers; admitted October 17, 1863. Chronic diarrhœa. Died, October 29th. *Autopsy* eleven hours after death: Body moderately emaciated. Brain not examined. The lungs, pleuræ and heart were normal, as were also the liver, spleen and kidneys. The mesenteric glands were greatly enlarged. The mucous membrane of the stomach was slightly inflamed; that of the small intestine very much inflamed and extensively ulcerated, especially in its lower portion, which presented a number of longitudinal ulcers from two to four inches in length, was of a dark livid color and very offensive odor. The colon also was much inflamed, and contained numerous small ulcers.

CASE 716.—Private Justus A. Balcom, company G, 21st Michigan volunteers; age 20; admitted from the field hospital of the army of the Cumberland, near Stevenson, Alabama, October 23, 1863. Chronic diarrhœa. Died, October 31st. *Autopsy* twelve hours after death: Body moderately emaciated and very pale. Brain not examined. There were pleuritic adhesions on

the left side, and about half a pint of serum in the left pleural sac. The heart was healthy, and had large post mortem clots in its cavities. The lower lobe of the left lung and the posterior portion of the upper lobe were in the stage of gray hepatization; the right lung was healthy but somewhat congested at its base. The liver was very large, but apparently healthy, except that it was a little darker than usual. The spleen was as large again as usual, and much darker. The kidneys and bladder were healthy. The mesenteric glands were slightly enlarged. The mucous membrane of the stomach was slightly inflamed; that of the lower portion of the small intestine and of the colon was somewhat inflamed and abraded.

CASE 717.—Corporal James Lucas, company G, 15th United States infantry; age 23; admitted October 23, 1863. Chronic diarrhœa. Died, October 31st. *Autopsy* thirty hours after death: Body very greatly emaciated. Brain not examined. There were recent pleuritic adhesions on the right side. Both lungs contained softened tubercles, and there was a cicatrix (apparently) at the apex of the left lung. The pericardium contained about five or six ounces of fluid. The heart was healthy and of natural size. The liver, spleen, kidneys and bladder were healthy. The mesenteric glands were very much enlarged. The stomach was healthy. There was extensive inflammation and abrasion of the small intestine, with deep and numerous ulcers in the colon.

CASE 718.—Private Michael Keiner, company K, 21st Wisconsin volunteers; age 38; admitted October 17, 1863. Chronic diarrhœa. Died, November 4th. *Autopsy* thirty-six hours after death: Body very greatly emaciated. Brain not examined. There were slight recent pleuritic adhesions on the right side; a few isolated and softened tubercles in the apex of the left lung, and slight congestion, with some tubercles, in the base and posterior part of the right lung; both lungs contained an excess of black pigment. The pericardium and heart were normal. The liver was enlarged and tough; it weighed four pounds and two-tenths. The spleen weighed six ounces and a half. The left kidney was engorged and weighed six ounces and a half; the right kidney weighed four ounces and a half. The mesenteric glands were much enlarged. The stomach was natural. The small intestine was inflamed and slightly abraded; the large intestine inflamed and ulcerated.

CASE 719.—Private William Melendy, company K, 44th Indiana volunteers; age 28; admitted October 23, 1863. Chronic dysentery. Died, November 10th. *Autopsy* fifty hours after death: Body greatly emaciated. There were no pleuritic adhesions. The apices of the lungs contained deposits of tubercles, and the bronchial tubes contained a dark puriform matter. The pericardium and heart were healthy; the heart weighed ten ounces. There was considerable peritoneal inflammation, especially in the pelvic region. The intestines were coated with lymph, and three or four ounces of pus were found in the pelvic cavity. The liver appeared to be normal; it weighed three pounds and a half. The spleen was healthy and weighed ten ounces. The kidneys were healthy and weighed four ounces each. The mesenteric glands were much enlarged. The stomach was distended with a dark fluid. The duodenum was slightly inflamed. The large intestine was extensively and deeply ulcerated; the ulcers had indurated edges and in some places had almost perforated.

CASE 720.—Private Elijah Ramsay, company A, 5th East Tennessee cavalry; age 27; admitted October 17, 1863. Chronic diarrhœa. Died, November 10th. *Autopsy* thirty-eight hours after death: Body moderately emaciated; eyes mortified [?]. There were numerous pleuritic adhesions on the right side. Softened tubercles were found at the apex of the right lung. The mucous membrane of the bronchial tubes was much thickened. The pericardium and heart were healthy; the heart weighed eight ounces. The liver weighed four pounds and a half; the gall-bladder was very much distended with bile. The spleen weighed eight ounces. The mesenteric glands were much enlarged. The right kidney weighed six ounces, the left six and a half. The stomach appeared to be healthy but contained a very dark fluid. The duodenum was slightly inflamed. The large intestine was extensively abraded, and presented numerous ulcers with indurated edges.

CASE 721.—Private Ephraim Lambert, company F, 92d Illinois volunteers; age 21; admitted October 17, 1863. Chronic diarrhœa. Died, November 13th. *Autopsy* twenty-six hours after death: Body very greatly emaciated. There were pleuritic adhesions on the left side, and a few hard calcareous tubercles in the apex of the left lung; in the apex of the right lung there were a number of softened tubercles; the posterior parts of both lungs were slightly congested. The pericardium and heart were healthy, the latter weighing only six ounces and a half; the cavities of the heart contained large post mortem clots, partly light-yellow and partly dark colored. The liver was healthy in structure and weighed two pounds ten ounces; the gall-bladder was distended with a light-yellow fluid, which had but little appearance of bile. The spleen was healthy and weighed four ounces. The kidneys were also healthy; the right weighed three ounces and a half, the left four and a half. The mesenteric glands were very much enlarged. The stomach presented patches of congestion near the cardiac orifice. Similar congested areas were found in the small intestine. The colon was extensively and deeply ulcerated; the ulcers had jagged indurated edges. A fibro-calcareous tumor, about three-quarters of an inch in diameter, was found attached to the ileum by a slender pedicle half an inch in length.—Assistant Surgeon Charles J. Kipp, U. S. V. [No. 53, Medical Section, Army Medical Museum, is from this case. The specimen consists of a portion of the ileum with the tumor just described; it proved to be composed of dense connective tissue in which there was an irregular deposit of calcareous matter, giving it a bone-like hardness.]

CASE 722.—Private William E. Smith, company B, 12th East Tennessee cavalry; admitted October 24, 1863. Acute bronchitis. Died, November 18th. *Autopsy* sixteen hours after death: Body but little emaciated. There were no pleuritic adhesions. The heart was healthy in structure and contained yellowish clots in the left ventricle; it weighed eleven ounces. The pericardium was healthy. There were a few tubercles at the base of each lung. The larynx was slightly inflamed. The lower portion of the trachea and the bronchial tubes were highly inflamed, and the smaller bronchial tubes contained a quantity of purulent fluid. The liver appeared to be healthy; it weighed three pounds and a half. The spleen weighed eight ounces. The right kidney weighed eight ounces, the left ten; both contained tubercles the size of millet-seed; these were found in all parts of the organ, but were most abundant in the cortical portion immediately beneath its surface. There was a small patch of inflammation near the cardiac orifice of the stomach. In the small intestine there were several patches of severe inflammation. The large intestine was generally inflamed and presented a few small ulcers. A lumbricoid worm about a foot long was found in the cæcum.

CASE 723.—Private John Glaspey, company F, 33d Ohio volunteers; admitted from the field hospital of the army of the Cumberland, Stevenson, Alabama, October 23, 1863. Chronic diarrhœa. Died, November 20th. *Autopsy* twenty-four hours after death: Body greatly emaciated; abdomen tympanitic and of a livid color. There were strong pleuritic adhesions on the right side. The right lung was filled with tubercular deposits, most of them completely broken down into pus; there were large cavities at the apices of the lungs; the lower lobe of the left lung was in the stage of gray hepatization. The heart was healthy and weighed nine ounces; there was a firm light colored clot in the left ventricle. The liver was dark colored, but of healthy consistence; it weighed three pounds seven ounces; the gall-bladder was empty. The kidneys weighed six ounces each. The spleen weighed nine ounces. The mesenteric glands were very much enlarged. There were numerous tubercular deposits throughout the small intestine, [enlarged solitary follicles?] and several ulcers in the mucous membrane of the large intestine.

CASE 724.—Private Joseph Wells, company C, 90th Illinois volunteers; age 24; admitted November 17, 1863. Diarrhœa. Died, November 28th. *Autopsy* twenty-two hours after death: Body very much emaciated. The base of the right lung was slightly congested and contained a large calcareous tubercle. The bronchial tubes contained a small quantity of light puriform matter. The heart was healthy and weighed eight ounces; there were small fibrinous clots in the cavities of both sides. The spleen weighed seven ounces and a half. The kidneys weighed six ounces each. The mesenteric glands were very much enlarged, and the mesentery very much congested. The stomach was contracted and its mucous membrane thrown into longitudinal folds. The mucous membrane of the small intestine and of the cæcum was very extensively inflamed. The colon and rectum presented numerous large, deep, ragged ulcers.

CASE 725.—Corporal David M. Chatfield, company D, 2d Indiana cavalry; age 25; admitted November 17, 1863. Chronic diarrhœa. Died, December 7th, of double pneumonia. *Autopsy* nineteen hours after death: Body very little emaciated. There were recent pleuritic adhesions on both sides. The upper lobe and the upper portion of the lower lobe of the right lung were in the stage of gray hepatization; the lower lobe of the left lung and the lower portion of the upper lobe were hepatized red, approaching gray. The heart was healthy and weighed eleven ounces and a half. The liver weighed five pounds six ounces. The spleen weighed nine ounces. The kidneys weighed seven ounces and a half each. The bladder was greatly distended with urine. The mesenteric glands were somewhat enlarged. The stomach was healthy. There were a few small patches of inflammation in the small intestine. The large intestine was healthy.

CASE 726.—Private George Weldon, company M, 6th Kentucky cavalry; age 21; admitted December 3, 1863. Chronic diarrhœa. Died, December 7th. *Autopsy* twenty-one hours after death: Body moderately emaciated. There were recent pleuritic adhesions on the left side, and both lungs were firmly adherent to the diaphragm. The heart was healthy and weighed nine ounces and a half. The liver weighed four pounds four ounces. The spleen was light colored but of normal texture, and weighed twelve ounces. The kidneys weighed five ounces and a half each. The mesenteric glands were very much enlarged. The stomach was healthy. There were several patches of inflammation in the small intestine. The large intestine was highly inflamed; its mucous membrane was thickened and presented several large isolated ulcers.

CASE 727.—Private Christopher Walter, company A, 99th Ohio volunteers; age 27; admitted December 3, 1863. Chronic diarrhœa. Died, December 21st. *Autopsy* twenty-four hours after death: Body greatly emaciated. There were recent pleuritic adhesions on the right side. The lower lobe of the right lung, and the lower portions of the middle and upper lobes were hepatized red; the lower and posterior portions of both lobes of the left lung were also hepatized. The heart weighed twelve ounces and contained a large firm light-yellow clot. The omentum was atrophied, a few shreds only remaining. The liver weighed four pounds and a half; the spleen six ounces. The lungs, liver and spleen were filled and covered over with small light yellow masses about the size of mustard-seeds, or rather larger; these had the appearance of tubercles, were of firm consistence, and were closely adherent to the adjacent tissue; they were more abundant in the liver and spleen than in the lungs, and were more numerous on the surface than through the substance of the organs. The right kidney weighed eight ounces, the left nine and a half. The mesenteric glands were very much enlarged. The mucous membrane of the stomach was inflamed, and near the pyloric orifice very much thickened; that of the small intestine was extensively inflamed and presented a few slight abrasions. The mucous membrane of the colon and rectum was also inflamed and presented a few isolated ulcers. The cæcum was free from disease.

CASE 728.—Private Abner A. Wheeler, company B, 63d Illinois volunteers; admitted from hospital No. 13, December 28, 1863. Chronic diarrhœa. Died, December 29th. *Autopsy* thirty-six hours after death: Body moderately emaciated. There were slight pleuritic adhesions on both sides. In the left lung there was a calcareous tubercle the size of a pea; the lower lobe of the right lung was much congested. The heart was healthy and weighed nine ounces. The liver weighed five pounds and a half; it appeared to be somewhat fatty, and contained a few small purulent collections. The spleen weighed one pound and was somewhat indurated. The ascending, transverse and descending colon, and the rectum were very much inflamed and ulcerated; in the transverse colon there were several perforations [?]. The omentum and mesentery contained an unusual amount of fat.

CASE 729.—Private Patrick H. Kimbro, company A, 18th Alabama, (rebel;) admitted January 4, 1864. Chronic diarrhœa. Died, January 5th, of peritonitis. *Autopsy* thirty-six hours after death: Body greatly emaciated; abdomen somewhat distended with fluid; the whole surface had a deep icteroid hue. There were strong pleuritic adhesions on the right side. The lower lobe of the right lung was congested. The pericardium and heart were healthy; the heart weighed eleven ounces. The abdominal cavity contained about a gallon of high colored serum, which was mingled with pus in the pelvic cavity. There were a few small blood-clots between the peritoneum and the abdominal walls. The intestines were connected with the anterior abdominal walls by large deposits of lymph, by which also the knuckles of intestine were connected together. The liver weighed three pounds three ounces; it was firm in texture, and externally of a dirty brown color; the gall-bladder contained a dark-brown tenacious fluid. The spleen was healthy and weighed one pound. Both kidneys had a dirty yellowish appearance; the right weighed six ounces, the left seven. [The condition of the intestinal mucous membrane is not recorded.]

CASE 730.—Private John R. Cherry, company D, 32d Alabama, (rebel;) admitted December 31, 1863. Chronic diarrhœa. Died, January 6, 1864. *Autopsy* thirty-six hours after death: Body greatly emaciated. The upper lobe of the right lung was strongly attached to the posterior walls of the chest and contained numerous large tubercles and several cavities; the lower lobe was hepatized red; the upper lobe of the left lung was filled with tubercles. The heart was healthy and weighed nine ounces and a half. The liver weighed two pounds ten ounces. The spleen weighed seven ounces. The right kidney weighed four ounces and a half, the left five ounces. The mesenteric glands were very much enlarged. The mucous membrane of the small intestine was inflamed. [The condition of the large intestine is not recorded.]

CASE 731.—Private Jesse Leaper, company I, 4th Indiana cavalry; admitted December 21, 1863. Chronic diarrhœa. [This man also appears on the register of hospital No. 3, Nashville, admitted December 18th—chronic diarrhœa—sent to general hospital December 21st.] Died, January 7, 1864. *Autopsy* eighteen hours after death: Body greatly emaciated. The thoracic viscera were healthy. The heart weighed seven ounces and a half. The liver weighed three pounds three ounces; the spleen eight ounces. The kidneys weighed six ounces and a half each. The mesenteric glands were very much enlarged. The mucous membrane of the small intestine was a good deal inflamed. The large intestine presented numerous enormously large and deep ulcers, some of them almost perforating the intestinal coats.

CASE 732.—Private John W. Riley, company B, 32d Alabama, (rebel;) age 43; admitted January 4, 1864. Diarrhœa. Died, January 10th. *Autopsy* thirty-six hours after death: Body greatly emaciated. The lower lobe of the right lung and the posterior portions of both lobes of the left were hepatized gray. The heart weighed nine ounces. The liver weighed three pounds four ounces. The spleen weighed eight ounces. The kidneys were fatty and weighed six ounces each; the bladder was distended with urine. The mesenteric glands were slightly enlarged. The stomach, small intestine and rectum were healthy. The transverse and descending colon presented numerous small recent ulcers.

CASE 733.—Private John H. Barnes, company F, 9th Mississippi, (rebel;) admitted January 3, 1864. Rheumatism. Died, January 12th, of chronic dysentery. *Autopsy* twelve hours after death: Body greatly emaciated. There were strong pleuritic adhesions on the right side. The greater portion of the lower lobe of the left lung was engorged, and the whole of the posterior portion of the right lung was hepatized red. The heart was healthy and weighed seven ounces. The liver was slightly congested and weighed four pounds. The spleen weighed eight ounces. The kidneys were slightly engorged; the right weighed seven ounces, the left eight. The mesenteric glands were very greatly enlarged. The mucous membrane of the stomach was highly inflamed. The small intestine was generally inflamed; and the mucous membrane of the colon and rectum was entirely destroyed by ulceration.

CASE 734.—Private Frank Gangloff, company C, 69th Ohio volunteers; age 54; admitted December 28, 1863. Chronic diarrhœa. [This man appears on the register of the hospital of his regiment, sent to Chattanooga, December 16th; no diagnosis. He appears on the records of the medical director's office, Chattanooga, admitted December 15th—rheumatism; no disposition; and on the register of hospital No. 12, Nashville, admitted December 25th—chronic diarrhœa—sent to general hospital December 28th.] Died, January 13, 1864. *Autopsy* fifteen hours after death: Body greatly emaciated. There were tubercular deposits, beginning to soften, in the upper lobe of each lung. The heart was healthy and weighed seven ounces. The liver weighed three pounds fifteen ounces. The spleen weighed five ounces. The right kidney weighed four ounces and a half, the left, which was slightly congested, weighed five ounces and a half; the bladder was distended with urine. The mesenteric glands were somewhat enlarged. The mucous membrane of the greater curvature of the stomach and of the lower portion of the small intestine was slightly inflamed. The lower portion of the colon and the whole of the rectum presented numerous large and apparently old ulcers, some of which appeared to be cicatrizing.

CASE 735.—Private John P. Turner, company G, 18th Alabama, (rebel;) admitted from prison hospital January 2, 1864. Intermittent fever. Died, January 15th, of chronic diarrhœa and pneumonia. *Autopsy* twelve hours after death: The body was generally œdematous; the abdomen a good deal distended. There were extensive pleuritic adhesions on the right side. The lower lobe of the right lung was in the stage of red hepatization, and the posterior portion of the upper and middle lobes highly congested; the lower lobe of the left lung was congested. The heart weighed eight ounces; its mitral valves were a good deal thickened. The abdomen contained about three pints of clear serum. The liver weighed two pounds ten ounces. The spleen weighed five ounces. The right kidney weighed six ounces and a half, the left four and a half. The mesenteric glands were slightly enlarged. The stomach and intestines were distended with gas. The mucous membrane of the small intestine was much inflamed; that of the large intestine inflamed and ulcerated. There were small deposits of lymph on the surface of the intestines and mesentery.

CASE 736.—Private Jacob Wright, company C, 88th Illinois volunteers; age 22; admitted November 7, 1863. Chronic dysentery. Died, January 15, 1864. *Autopsy* fifteen hours after death: Body very greatly emaciated. There were slight pleuritic adhesions on the right side, and strong ones on the left side posteriorly. The lower lobe of the left lung and the lower portion of the upper lobe were in the stage of gray hepatization; the lower lobe of the right lung was somewhat congested. The heart weighed eight ounces and contained large light yellow clots. The liver weighed three pounds and a half; it was somewhat fatty. The spleen was congested and weighed thirteen ounces. The right kidney weighed four ounces, the left five. The mesenteric glands were very much enlarged. The stomach was healthy. The small intestine presented a few patches of slight inflammation. The cæcum was highly inflamed and its mucous membrane a good deal abraded. The lower portion of the colon and the rectum were extensively and deeply ulcerated.

CASE 737.—Private Jacob Keifauber, company H, 97th Illinois volunteers; age 22; admitted December 2, 1863. Chronic dysentery. [This man appears on the hospital register of his regiment, admitted October 2d—chronic diarrhœa—sent to convalescent camp October 10th. No subsequent record is found until his admission to this hospital.] Died, January 17,

1864. *Autopsy* twenty-four hours after death: Body greatly emaciated. The lower portion of the lower lobe of the right lung was solidified, approximating the stage of gray hepatization. The heart weighed twelve ounces. The liver weighed four pounds eleven ounces. The spleen was of a dirty brown color and weighed one pound. The kidneys were a good deal congested and weighed seven ounces each. The peritoneum was somewhat inflamed, and there were small deposits of lymph on the surface of the intestines and the mesentery. The mesenteric glands were somewhat enlarged. The mucous membrane of the lower portion of the small intestine was inflamed. In the lower portion of the colon and throughout the rectum there were numerous ulcers, some of which were very deep.

CASE 738.—Private John Cole, company B, 81st Illinois volunteers; admitted January 4, 1864. Intermittent fever. Died, January 17th, of chronic diarrhœa. *Autopsy* twenty-four hours after death: Body moderately emaciated; legs and feet œdematous. There were strong pleuritic adhesions on the right side. The right lung was in the stage of gray hepatization. The pericardium contained about an ounce of serum. The heart weighed twelve ounces, and contained a large light yellow clot in its right ventricle, a large dark clot in the left. The liver was of a very light yellow color, fatty, and weighed four pounds and a half. The cortical portion of both kidneys was very light colored; they weighed six ounces and a half each. The spleen weighed eight ounces. The mesenteric glands were enlarged. The small intestine was inflamed, the large intestine ulcerated.

CASE 739.—Private William Dunsmore, company B, 37th Tennessee, (rebel;) admitted from prison hospital January 4, 1864. Diarrhœa. Died, January 19th, of pneumonia. *Autopsy* six hours after death: Body greatly emaciated. The lower portion of the lower lobe of the right lung was in the stage of red hepatization. The heart weighed six ounces. The liver was very dark colored and weighed two pounds ten ounces. The spleen was healthy and weighed five ounces. Both kidneys were healthy; they weighed three ounces and a half each. The mesenteric glands were somewhat enlarged. The lower portion of the small intestine was inflamed. The large intestine was ulcerated.

CASE 740.—Private Levi Rucker, company B, 31st Iowa volunteers; age 32; admitted December 3, 1863. Chronic diarrhœa. Died, January 22, 1864, of consumption and chronic diarrhœa. *Autopsy* eighteen hours after death: Body very greatly emaciated. There were extensive pleuritic adhesions on the right side; the right pleural sac contained about four ounces of serum, the left pleural cavity about eight ounces. The lower lobe of the right lung was congested, the middle lobe in the stage of gray hepatization; in the upper lobe there were many soft tubercles and several small vomicæ; the upper lobe of the left lung also was filled with soft tuberculous matter, and there were some large vomicæ at its apex. The heart weighed seven ounces. The liver weighed two pounds fourteen ounces. The right kidney weighed five ounces and a half, the left six ounces. The spleen weighed seven ounces. The mesenteric glands were unusually enlarged, and contained cheesy tuberculous deposits. Peyer's patches were very much thickened, and some of them were ulcerated. The lower portion of the small intestine was greatly inflamed. The rectum was inflamed and presented a few ulcers.

CASE 741.—Private Prescora Drake, company A, 66th Georgia, (rebel;) admitted from Provost Marshal January 7, 1864. Chronic diarrhœa. Died, January 23d. *Autopsy* thirty-six hours after death: Body greatly emaciated. There were no pleuritic adhesions, and the lungs were healthy. The heart was healthy and weighed seven ounces and a half. The liver weighed four pounds two ounces. The spleen weighed sixteen ounces. The right kidney weighed four ounces, the left five. The mesenteric glands were enlarged. The large intestine was ulcerated.

CASE 742.—Private Francis J. Calhoun, company B, 4th Florida, (rebel;) age 20; admitted from prison hospital January 2, 1864. Intermittent fever. Died, January 26th, of chronic diarrhœa. *Autopsy* twenty hours after death: Body greatly emaciated. There were recent pleuritic adhesions on the left side, and the posterior portion of the lower lobe of each lung was hepatized gray. The pericardium was slightly inflamed and contained about an ounce of serum. The heart was healthy and weighed six ounces and a half. The liver weighed two pounds and a half; the spleen seven ounces. The right kidney weighed three ounces, the left four. The mesenteric glands were very much enlarged. The small intestine was extensively inflamed; the large intestine inflamed and extensively ulcerated. The mucous membrane of the stomach, near the pyloric orifice, was also inflamed.

CASE 743.—Bryant Thornhill, rebel citizen, Jackson, Alabama; age 27; admitted from Provost Marshal January 5, 1864. Chronic diarrhœa. Died, January 28th. *Autopsy* eight hours after death: Body moderately emaciated. The lungs contained a few small calcareous tubercles at the apex of each; in other respects they were healthy. The pericardium was slightly inflamed and contained about half an ounce of serum. The heart weighed eight ounces; its valves were slightly thickened. The liver weighed three pounds three ounces; the gall-bladder contained six small very dark-colored gall-stones. The spleen was healthy and weighed nine ounces. Both kidneys were healthy; they weighed five ounces each; the bladder was somewhat distended with urine. The mucous membrane of the stomach, near the cardiac orifice, was inflamed. The lower portion of the small intestine was a good deal inflamed, and there were a few ulcers of Peyer's patches. The colon was extensively inflamed and contained numerous recent superficial ulcers.

CASE 744.—William Street, citizen, Dade County, Georgia, (rebel;) age 53; admitted January 26, 1864. Chronic diarrhœa. Died, January 29th. *Autopsy* ten hours after death: Body moderately emaciated. There were recent pleuritic adhesions on the right side posteriorly. The heart was fatty and weighed twelve ounces. The liver weighed three pounds twelve ounces; it was fatty and of a very light yellow color. The spleen weighed twelve ounces. The right kidney weighed eight ounces, the left nine. The colon was ulcerated.

CASE 745.—Samuel K. Smith, citizen, Maury County, Tennessee, (rebel;) age 57; admitted from prison hospital January 4, 1864. Rheumatism. Died, January 29th, of chronic dysentery. *Autopsy* twenty hours after death: Body moderately emaciated. There were tolerably strong pleuritic adhesions on both sides. The posterior portion of the middle and lower lobes

of the right lung was in the stage of red hepatization; the posterior portion of the left lung was in the stage of gray hepatization. The heart weighed nine ounces and a half; its valves were slightly thickened. The liver was fatty; it weighed three pounds eleven ounces, and was very yellow and soft. The spleen weighed three ounces and a half and contained a few small calcareous deposits. The kidneys were healthy; the right weighed three ounces, the left three and a half. The stomach was slightly inflamed. The small intestine contained four lumbricoid worms which averaged ten inches in length. In the large intestine there were numerous large ulcers.

CASE 746.—Joseph B. Bean, citizen, Catoosa County, Georgia, (rebel;) age 65; admitted from Provost Marshal January 10, 1864. Dysentery. Died, January 29th. *Autopsy* twenty hours after death: Body moderately emaciated. There were strong pleuritic adhesions on the left side posteriorly. The lower lobe and posterior portion of the upper lobe of the left lung were in the stage of red hepatization. The heart weighed nine ounces and a half. The aortic semilunar valves were calcareous, and the arteries of the body were everywhere atheromatous and calcareous. The liver was fatty and weighed three pounds. The spleen weighed six ounces. The kidneys weighed four ounces each. In the large intestine there were numerous small ulcers. —Surgeon C. W. Horner, U. S. V. [Nos. 310 to 312, Medical Section, Army Medical Museum, are from this case. No. 310 is the heart laid open to expose the valves. The aortic valves are the seat of calcareous deposits, and there are calcareous atheromatous patches in the aorta just above the valves. The other vessels are healthy. No. 311 is the arch and a part of the descending aorta, presenting numerous atheromatous patches with calcareous deposits in many places. No. 312 is the lower part of the descending aorta with a part of the common iliacs. In this part of the vessel the atheromatous disease is present in a higher degree, and fibrinous clots, derived from the blood, adhere to many of the roughened patches.]

CASE 747.—Private Albert Gilbert, company C, 22d Missouri, (rebel;) admitted January 2, 1864. Intermittent fever. Died, February 4th, of chronic dysentery. *Autopsy* thirty-six hours after death: Body moderately emaciated. The lower lobe of the left lung and the lower and middle lobes of the right were in a state of red hepatization approximating gray. The heart weighed nine ounces. The liver weighed four pounds seven ounces; it was of a very light yellow color and fatty. The spleen was healthy and weighed two ounces and a half. The right kidney weighed five ounces, the left four. The stomach was apparently healthy. The colon and rectum were full of very large and apparently old ulcers.

CASE 748.—Private John Morrisy, company B, 4th Michigan cavalry; admitted December 21, 1863. Chronic rheumatism. Died, February 8, 1864, of bronchitis and chronic dysentery. *Autopsy* thirty-six hours after death: Body moderately emaciated. There were slight pleuritic adhesions on the left side. There were a few tubercles in each lung, the majority of which were softened; the posterior portion of both lungs was a good deal congested. The mucous membrane of the bronchial tubes was very much inflamed, and the tubes contained a purulent fluid. The heart weighed eight ounces and contained very dark blood-clots. The liver was fatty and weighed three pounds two ounces. The spleen weighed six ounces. The kidneys were apparently contracted, the cortical portion being firmer and a good deal lighter than usual; the right weighed three ounces and a half, the left four ounces. The stomach was healthy. The small intestine was slightly inflamed, and there were a few ulcers of Peyer's patches which were transverse to the course of the intestine. The cæcum was highly inflamed, and the colon and rectum extensively ulcerated, but the ulcers were not very deep.

CASE 749.—Private James Strickland, company D, 1st Georgia, (rebel;) admitted February 2, 1864. Chronic diarrhœa. Died, February 9th, of pleuro-pneumonia. *Autopsy* six hours after death: There were strong old pleuritic adhesions about the apex of the right lung, and about half a pint of sero-sanguineous fluid in each pleural cavity; the middle and upper lobes of the right and the lower lobe of the left lung were in the stage of red hepatization; the remainder of the lungs was deeply engorged. The pericardium contained about an ounce and a half of serum. The heart weighed nine ounces and a half; there were large yellow clots in its right side. The liver weighed three pounds seven ounces; it was fatty and of a deep-yellow color. The spleen weighed three ounces. The kidneys were of a very light color; the right weighed seven ounces, the left seven and a half. The mesenteric glands were slightly enlarged. The stomach was a good deal inflamed, and a large patch of mucous membrane near the cardiac orifice was thickened and presented several slight abrasions. The small intestine was healthy, and there was a little inflammation in the rectum. The bladder was distended with urine.

CASE 750.—Private William Rogers, company C, 36th Indiana volunteers; age 24; admitted from Chattanooga February 4, 1864. Typhoid fever [?]. Died, February 9th, of chronic dysentery. *Autopsy* eighteen hours after death: Body greatly emaciated. The posterior portion of each lung was congested. The pericardium contained about an ounce of serum. The heart weighed eight ounces. The liver was slightly fatty and weighed five pounds one ounce. The spleen weighed eight ounces. The kidneys weighed five ounces and a half each. The mesenteric glands were a good deal enlarged. The peritoneum was inflamed. The intestines were very dark exteriorly, and were glued together in several places by deposits of lymph. The lower portion of the mucous membrane of the small intestine was highly inflamed and ulcerated. The cæcum was full of extremely large ulcers, one of which had perforated; this perforation was very large, and was about an inch and a half from the orifice of the appendix vermiformis. The colon and rectum contained numerous very large ulcers, and there were two large perforations in the colon; through the perforations fæcal matter had passed into the abdominal cavity.

CASE 751.—Private Joel L. Brooks, company G, 35th Illinois volunteers; age 33; admitted February 2, 1864. Chronic diarrhœa. [This man appears on the register of the field hospital, Chattanooga, Tennessee, admitted January 8th—chronic diarrhœa—sent to general hospital February 1st.] Died, February 12th, of chronic dysentery. *Autopsy* twelve hours after death: Body very little emaciated. There was a small bony deposit in the substance of the dura mater, corresponding with a slight depression of the frontal bone about an inch above the right orbital plate; the pia mater was slightly congested, and the subarachnoid cavity contained about half an ounce of serum. There was a slight deposit of lymph upon the choroid plexus. There were moderately strong pleuritic adhesions on both sides. The lower lobe of the left and the lower and middle lobes of the right lung were deeply engorged. The pericardium contained about an ounce of serum; the heart weighed ten ounces and contained

moderately large light yellow clots. The liver was rather firm, of a light yellow color, and weighed four pounds two ounces; the gall-bladder contained about six ounces of bile. The spleen weighed nine ounces. The right kidney weighed seven ounces, the left seven and a half. The stomach contained a little mucus. The small intestine was slightly inflamed in patches. [The condition of the large intestine is not recorded.]

CASE 752.—Private Isaac Bricker, company M, 10th Ohio cavalry; age 25; admitted February 4, 1864. Chronic diarrhœa. [This man appears on the register of the field hospital, Chattanooga, Tennessee, admitted January 12th—chronic diarrhœa—sent to general hospital February 3d.] Died, February 13th. *Autopsy* eighteen hours after death: Body greatly emaciated. On the right side of the forehead there was a cicatrix two inches in length, covering a corresponding gap in the outer table of the frontal bone an inch in length and an inch above the right superciliary ridge; there was no depression of the internal table. There was some appearance of lymph deposits on the superior surface of the cerebrum. The lower lobe of the left lung was in the stage of gray hepatization; the lower lobe of the right lung was deeply engorged, and throughout the lung-tissue there were several firm well-defined blood-clots. The heart weighed eight ounces and contained small light yellow clots. The liver was fatty and weighed three pounds twelve ounces. The spleen was firm and weighed fourteen ounces. The right kidney weighed eight ounces, the left eight and a half. The mesenteric glands were very much enlarged. The duodenum and the lower portion of the small intestine were inflamed. Peyer's patches were a good deal injected. [The condition of the large intestine is not recorded.]

CASE 753.—Private Charles L. Busher, company K, 1st Ohio volunteers; admitted February 4, 1864. Chronic diarrhœa. [This man appears on the register of the field hospital, Chattanooga, Tennessee, admitted January 26th—chronic diarrhœa—sent to Nashville February 3d.] Died, February 15th. *Autopsy* twenty-four hours after death: Body moderately emaciated. There were pleuritic adhesions on the left side. The lower lobe of the left lung was in the stage of red hepatization and coated externally with lymph; the lung weighed two pounds two ounces; the right lung was healthy. The heart weighed eleven ounces. The liver weighed four pounds twelve ounces. The spleen weighed five ounces and a half. The right kidney weighed seven ounces, the left seven and a half. The mucous membrane of the stomach and duodenum was inflamed. The colon and rectum were ulcerated.

CASE 754.—Private Charles Albert, company B, 35th Ohio volunteers; admitted from Chattanooga February 14, 1864. Chronic diarrhœa. Died, February 15th. *Autopsy* twenty-four hours after death: Body greatly emaciated. The lungs and heart were healthy. Nothing abnormal was noted in the liver, spleen, kidneys or stomach. The small intestine was slightly inflamed. The large intestine was extensively ulcerated.

CASE 755.—Private John McMahon, company D, 2d battalion, 16th United States Infantry; age 40; admitted February 14, 1864. Chronic diarrhœa. [This man appears upon the register of the field hospital of the army of the Cumberland, Chattanooga, Tennessee, admitted February 5th—chronic diarrhœa—sent to general hospital February 13th.] Died, February 16th. *Autopsy* twenty-four hours after death: Body very greatly emaciated. The lower lobe of the left lung was deeply engorged; the central part of the middle lobe of the right lung was in the stage of gray hepatization. The heart weighed eight ounces and contained large light yellow clots in its right side. The liver weighed two pounds fourteen ounces. The spleen weighed three ounces. The right kidney weighed five ounces and a half, the left six ounces. The mesenteric glands were very much enlarged. The stomach was healthy. The lower portion of the small intestine was a good deal inflamed. The colon and rectum were extensively ulcerated.

CASE 756.—Private Joseph Millican, citizen prisoner; admitted January 13, 1864. Diarrhœa. Died, February 17th. *Autopsy* twenty-four hours after death: Body very greatly emaciated. There were moderately strong pleuritic adhesions on the right side. Both lungs contained numerous tubercular deposits; in the apex of the left lung were several large cavities; the lower lobe of the lung was engorged with blood. The bronchial tubes were filled with a purulent fluid. The heart weighed five ounces and a half. The liver weighed two pounds seven ounces and was healthy. The spleen weighed nine ounces. The right kidney weighed three ounces and a half, the left four ounces. The ileum was inflamed. The sigmoid flexure and rectum were ulcerated.

CASE 757.—Private James W. Stewart, company E, 4th Florida, (rebel;) age 23; admitted January 27, 1864. Chronic diarrhœa. [This man appears upon the register of hospital No. 2, Nashville, admitted from Chattanooga December 8, 1863—bronchitis—sent to hospital No. 1 January 27th.] Died, February 18th. *Autopsy* twenty-four hours after death: Body greatly emaciated. The bronchial tubes were inflamed. The heart was normal. The liver was healthy. The spleen weighed fourteen ounces. There was fatty degeneration of both kidneys; the right weighed seven ounces and a half, the left eight ounces. The small intestine was normal. The large intestine was inflamed and ulcerated.

CASE 758.—Private Patrick Delaney, company G, 10th Tennessee, (rebel;) admitted from prison hospital January 4, 1864. Intermittent fever. Died, February 18th, of chronic diarrhœa. *Autopsy* thirty-six hours after death: Body greatly emaciated. There were slight pleuritic adhesions on the right side. There were several hepatized patches in the interior of both lungs. The heart weighed eight ounces and a half and contained large clots. The liver was fatty and weighed two pounds thirteen ounces; the gall-bladder was empty. The spleen weighed seven ounces. The right kidney weighed four ounces, the left four and a half. The stomach was healthy. The lower portion of the small intestine was inflamed. The colon and rectum were extensively ulcerated.

CASE 759.—Private Charles Bock, company H, 1st Wisconsin cavalry; age 29; admitted December 21, 1863. General debility. [The records of the medical director's office, Nashville, Tennessee, show that this man was admitted to hospital No. 21 November 29th; no diagnosis. He appears upon the records of hospital No. 13, admitted December 18th—remittent fever—sent to general hospital No. 1 December 21st.] Died, February 20, 1864, of chronic diarrhœa. *Autopsy* twelve hours after death: Body greatly emaciated. The large bronchial tubes were inflamed on the right side, and there were old pleuritic adhesions in the right pleural sac. The heart weighed six ounces. The liver weighed two pounds five ounces. The spleen weighed

six ounces. The right kidney weighed five ounces and a half, the left six and a half. The intestines were greatly distended with gas, displacing the liver upward. The whole extent of the small intestine was congested, and in some places ulcerated. The colon and rectum were thickened, ulcerated and of a very dark color.

CASE 760.—Private Joseph Bradham, company E, 38th Indiana volunteers; age 23; admitted February 2, 1864. Chronic diarrhœa. [This man appears on the register of the field hospital of the army of the Cumberland, Chattanooga, Tennessee, admitted January 25, 1864—dropsy—sent to Nashville February 2d.] Died, February 21st, of peritonitis. *Autopsy* twenty-four hours after death: Body greatly emaciated. There were slight pleuritic adhesions on each side, and each pleural cavity contained about four ounces of serum. The mucous membrane of the bronchi was a good deal inflamed, and the lower lobe of each lung engorged with blood. The heart weighed eight ounces. The abdomen contained about three pints of sero-purulent fluid. The intestines were coated and glued together with lymph. The liver was fatty and weighed three pounds twelve ounces. The spleen was healthy and weighed six ounces. The kidneys were rather soft and light colored; they weighed eight ounces and a half each. The mesenteric glands were very much enlarged. The mucous membrane of the stomach was very dark colored, and there were several patches of inflammation scattered along the mucous membrane of the intestines.

CASE 761.—Private James Brown, company D, 35th Illinois volunteers; age 23; admitted from Chattanooga, Tennessee, February 4, 1864. Chronic diarrhœa. Died, February 21st, of pneumonia. *Autopsy* twenty-four hours after death: Body greatly emaciated. The membranes of the brain were congested, and there were about two ounces of serum at the base of the brain. The left lung was healthy; the upper and middle lobes of the right lung were in the stage of red hepatization, the lower lobe hepatized red. The heart weighed nine ounces and a half. The liver weighed three pounds ten ounces. The spleen was engorged with blood and weighed fourteen ounces. The kidneys weighed eight ounces each. The stomach and duodenum were inflamed, and their mucous membrane was pulpy. Other parts of the small intestine were also inflamed. The colon and rectum were in a state of chronic inflammation.

CASE 762.—Private John Hennessee, company K, 35th Illinois volunteers; age 31; admitted February 2, 1864. Chronic diarrhœa. [This man appears on the register of the field hospital of the army of the Cumberland, Chattanooga, Tennessee, admitted January 8th—chronic diarrhœa—sent to Nashville January 30th.] Died, February 23d. *Autopsy* eighteen hours after death: There were slight pleuritic adhesions on both sides. The costal pleura of the left side presented numerous small firm masses apparently tubercular in their character. The lower portion of the right lung was in the stage of gray hepatization. The heart weighed nine ounces. The liver weighed four pounds three ounces; it was of a pale-purple color externally, and contained numerous small circumscribed collections of a pus-like fluid. The spleen weighed ten ounces and a half. The kidneys were healthy. The large intestine was ulcerated.

CASE 763.—Private Michael Dilland, company A, 47th Georgia, (rebel;) age 31; admitted January 27, 1864. Chronic diarrhœa. [This man appears on the register of hospital No. 2, Nashville, admitted December 11, 1863—chronic diarrhœa—sent to general hospital January 29, 1864.] Died, February 27th. *Autopsy* twelve hours after death: Body greatly emaciated. There were slight pleuritic adhesions on the left side. The posterior portions of the right lung were œdematous. The heart weighed eight ounces. The liver was fatty and weighed three pounds. The spleen was firm and weighed eighteen ounces. The kidneys were slightly congested and weighed five ounces each. The mesenteric glands were enlarged. The bladder was distended with urine. The lower portion of the small and the whole of the large intestine were highly inflamed and abraded.

CASE 764.—George P. Derrick, citizen, Marshall County, Alabama, (rebel;) age 42; admitted from the Provost Marshal January 23, 1864. Chronic diarrhœa. [This man appears on the register of hospital No. 2, Nashville, Tennessee, admitted December 11, 1863—pneumonia—sent to the Provost Marshal January 13, 1864.] Died, February 29th. *Autopsy* twenty-four hours after death: Body greatly emaciated. The thoracic viscera were healthy, as were also the liver, spleen and kidneys. The mesenteric glands were enlarged. The lower portion of the small intestine was highly inflamed. The large intestine was inflamed and extensively ulcerated.

CASE 765.—Private Edmund Bettis, company D, 25th Illinois volunteers; age 28; admitted February 2, 1864. Chronic diarrhœa. [This man appears upon the register of the general field hospital of the army of the Cumberland, Chattanooga, Tennessee, admitted January 8th—diarrhœa—sent to Nashville February 1st.] Died, March 2d. *Autopsy* twenty-hours after death: Body greatly emaciated. There were slight pleuritic adhesions posteriorly, and lobular hepatization in the lower lobe of each lung; the bronchial tubes contained a good deal of pus. The heart weighed six ounces. The liver weighed two pounds ten ounces; the spleen weighed four ounces. The kidneys were healthy and weighed four ounces and a half each. The mesenteric glands were slightly enlarged. The lower portion of the small intestine was a good deal inflamed, and the large intestine was extensively and deeply ulcerated.

CASE 766.—Corporal George W. Baxter, company G, 25th Georgia, (rebel;) age 22; admitted January 2, 1864. Dropsy. Died, March 9th, of chronic dysentery. *Autopsy* twenty-four hours after death: There were a few old pleuritic adhesions on the left side posteriorly. The lungs were healthy. The heart weighed seven ounces. The liver weighed three pounds; the gall-bladder was distended with bile. The right kidney weighed five, the left six ounces. The spleen weighed seven ounces and a half. The mesenteric glands were much enlarged. The large intestine was highly inflamed and ulcerated.

CASE 767.—Private Thomas H. Benson, company K, 16th South Carolina, (rebel;) age 35; admitted January 27, 1864. Anasarca. Died, March 10th, of chronic diarrhœa. *Autopsy* thirty hours after death: The right lung was healthy; the lower lobe of the left lung was hepatized red. The heart weighed six ounces and a half. The liver weighed two pounds eleven ounces; the spleen weighed four ounces and a half. The left kidney weighed five ounces, the right four and a half. The mucous membrane of the small intestine was injected; that of the large intestine was inflamed; the rectum was ulcerated at some points.

CASE 768.—Private John Luntsford, company I, 19th Tennessee, (rebel;) age 30; admitted January 1, 1864. Chronic diarrhœa. Died, March 12th, of pneumonia. *Autopsy* twenty-four hours after death: The lower lobes of both lungs and the

lower portion of the upper lobe of the right lung were hepatized; the upper lobe of the left lung was healthy. The heart weighed nine ounces; there were fibrinous clots in both ventricles. The liver weighed three pounds four ounces and a half. The spleen weighed five ounces. The kidneys weighed four ounces and a half each. The mucous membrane of the lower portion of the small intestine was inflamed. The descending colon and the rectum were ulcerated.

CASE 769.—Private George L. Koonts, company A, 39th Indiana volunteers; age 23; admitted from Chattanooga, Tennessee, February 14, 1864. Chronic diarrhœa. Died, March 12th. *Autopsy* twenty-four hours after death: The left lung was healthy; the upper lobe of the right lung was hepatized partly red, partly gray; the lower lobe was healthy. The heart weighed six ounces and a half. The liver was somewhat fatty and weighed forty-eight ounces and a half. Both kidneys were also fatty; the left weighed seven ounces and a half, the right seven ounces. The lower third of the small intestine was intensely inflamed. [There is no record of the condition of the large intestine.]

CASE 770.—Private Thaddeus Tillotson, company D, 15th United States Infantry; age 20; admitted February 2, 1864. Chronic diarrhœa. [This man appears upon the register of the field hospital of the army of the Cumberland, Chattanooga, Tennessee, admitted January 6th—diarrhœa—sent to Nashville February 1st.] Died, March 15th, of meningitis. *Autopsy:* The superficial vessels of the brain were congested. There were three ounces of serum and some lymph at the base of the brain; the ventricles were filled with serum. There were old pleuritic adhesions posteriorly on both sides. The apex of the right lung was infiltrated with tubercles; miliary tubercles were scattered through the rest of the right lung and the apex of the left lung. The heart weighed eight ounces. The liver was softened, adherent to the diaphragm, and weighed three pounds. The spleen also adhered to the diaphragm; it weighed five ounces. The right kidney weighed five ounces, the left five and a half. [The condition of the intestines is not recorded.]

CASE 771.—Private William J. Bryan, company H, 17th Tennessee, (rebel;) age 28; admitted March 7, 1864. Chronic diarrhœa. Died, March 16th. *Autopsy* twenty hours after death: Body greatly emaciated. The lungs were healthy. The heart weighed seven ounces. The liver weighed three pounds nine ounces. The spleen weighed eight ounces. The left kidney weighed five ounces, the right four and a half. The mesenteric glands were tubercular. The lower portion of the small intestine was extensively inflamed, and the colon and rectum were ulcerated.

CASE 772.—Private William J. Henry, company I, 1st Tennessee cavalry, (rebel;) age 30; admitted from Provost Marshal February 8, 1864. Chronic diarrhœa. Died, March 21st. *Autopsy* twelve hours after death: Body greatly emaciated. There were pleuritic adhesions on the right side. The right lung was very much congested The heart weighed six ounces. The liver weighed three pounds. The spleen was rather pulpy and weighed five ounces and a half. The right kidney weighed three ounces and a half, the left four ounces. The abdominal cavity contained about six ounces of serum, and there was a small deposit of pus over the lower portion of the bowels. The mucous membrane of the small intestine was extensively inflamed. The cæcum was very much ulcerated. In the colon and rectum there were numerous old ulcers, some of which had begun to cicatrize. There were two lumbricoid worms in the small intestine.

CASE 773.—Private Thomas Mayberry, company H, 12th Tennessee cavalry; age 43; admitted March 23, 1864. Chronic diarrhœa. Died, March 24th. *Autopsy* twenty-four hours after death: Body considerably emaciated. The right lung was adherent to the diaphragm. The bronchial mucous membrane of both lungs was inflamed, and the tubes contained a large quantity of thick mucus. The heart weighed eleven ounces. The liver weighed three pounds twelve ounces; the spleen weighed four ounces. The kidneys weighed four ounces and a half each. The stomach contained five large lumbricoid worms. The lower portion of the small intestine was very highly inflamed. Throughout the large intestine the mucous membrane was thickened, and presented innumerable superficial ulcers.

CASE 774.—Sergeant Edward R. Shepard, company M, 1st Wisconsin cavalry; age 25; admitted March 5, 1864. Chronic diarrhœa. Died, March 25th, of empyema. *Autopsy* twenty-four hours after death: There were extensive pleuritic adhesions on the right side, and deposits of lymph over the right lung; the right pleural sac contained fifty-five ounces of seropurulent fluid; the right lung was partially collapsed; the left pleural sac contained four ounces of serum; the left lung was greatly engorged but nowhere hepatized. The heart weighed eleven ounces. The liver weighed six pounds one ounce. The spleen weighed eight ounces and a half. The right kidney weighed six ounces and a half, the left seven ounces. Nothing abnormal was discovered in the intestines.

CASE 775.—Private Francis M. Gibson, company H, 5th Tennessee cavalry; age 30; admitted from Provost Marshal March 31, 1864. Typhoid pneumonia. Died, April 2d, of chronic diarrhœa. *Autopsy* twenty-four hours after death: The brain was normal and weighed forty-six ounces. The bronchial tubes of both lungs were inflamed. The heart weighed eight ounces and a half. The liver weighed three pounds. The spleen weighed ten ounces and a half. The kidneys were softer than normal; the right weighed three ounces, the left three and a half. The large intestine was ulcerated, and there were a few ulcers scattered through the small intestine.

The next seventeen cases, from HOSPITALS No. 2, 4, 6 and 14, Nashville, Tennessee, were forwarded with the report of Surgeon Ebenezer Swift, U. S. A., Medical Director of the Department of the Ohio and of the Cumberland for the year 1862. The number of the hospital is appended to each case. Thirteen of the cases are from Hospital No. 6, Surgeon Charles Schüssler, 6th Indiana volunteers, in charge.*

CASE 776.—Private Francis M. Howe, 13th Michigan volunteers; age 28; admitted June 25, 1862. This patient had marched with his regiment through Kentucky, reaching Nashville about the middle of March. He was soon after treated for

* For a special report, containing Surgeon Schüssler's views on chronic diarrhœa, see page 43 of this volume.

typhoid fever at hospital No. 1, where he was admitted April 1st, remaining until the middle of May. He was then transferred to the convalescent camp in the suburbs of the city, but complained continually of rheumatism and debility. He was finally transferred to the University hospital June 25th. At the time of admission the patient presented the appearance of a sunburnt, hearty, muscular, well-nourished man; the only visible sign of disease was considerable paleness of the tongue and of the palpebral conjunctivæ. He was ordered to take twenty drops of the tincture of the chloride of iron three times a day. July 1st: He experienced a slight chill, followed by a brief paroxysm of fever in the middle of the day. A scruple of quinine was administered July 2d, and from this time until July 11th there was no further complaint. Another slight chill, followed by fever and vomiting, then occurred, and a second scruple of quinine was administered on the next day. There were no repetitions of these chills, but on the 17th of July he complained of considerable pain in his limbs, attended with fetid perspiration. Ordered a scruple of Dover's powder in divided doses. This was followed next day by a scruple of quinine, also in divided doses. The patient now appeared to be completely relieved until the 24th of July, when he had a repetition of the fetid perspiration, but without a previous chill or fever. Ordered ten grains of Dover's powder every four hours, with four compound cathartic pills at bed-time, to be followed next day by a scruple of quinine in divided doses. July 25th and 26th: The patient expressed himself as feeling remarkably well, and performed guard duty about the premises; but during the night of July 26th he was attacked with diarrhœa, and had three light colored liquid stools during the night, followed by a fourth at breakfast-time next morning. The diarrhœa was not attended with pain or gastric uneasiness, and the appetite remained unimpaired. At 9 o'clock, when the morning visit was made, the patient complained of pains in the back and limbs, but did not mention the occurrence of diarrhœa during the previous night. Suspecting a recurrence of the malarial symptoms, a large dose of quinine was ordered to be taken immediately. This, however, was not administered. A few minutes after the departure of the medical attendant, who had remarked nothing unusual in the appearance of the patient, he received a hurried summons back to the ward, but before he could reach the place the man was dead. His companions stated that he had walked down stairs from the third story and had sat for a few minutes under a tree in the grounds of the hospital. He then returned to the ward, where he held some conversation concerning his diarrhœa, and spoke of a singular burning pain in his stomach and insatiable thirst, which was not relieved by draughts of water. He then reclined upon his bed, and was soon after seen to move his feet and jerk his head and elbows backward; his respiration at the same time became noisy, and froth appeared upon his lips. The whole cutaneous surface assumed a livid-purple color; it was moist but not cold. In less than two minutes life had departed. *Autopsy* five hours after death: Rigor mortis had not yet supervened. The whole body was warm and the skin was yet moist. The livid hue had disappeared except from the lips and nose and from the posterior portions of the body. The body was muscular and well clothed with adipose tissue. The arachnoid membrane was raised from the cerebrum by a considerable serous effusion; at the base of the brain there was not less than four ounces of fluid; the vessels of the pia mater and of the substance of the brain presented no unusual congestion; the amount of fluid in all the ventricles did not exceed three drachms. The substance of the lungs was perfectly healthy; the right lung was bound by old adhesions to the costal pleura; there was very little fluid in the left pleural cavity. The heart was healthy; its left ventricle was firmly contracted and was empty; the right ventricle contained a small colorless clot; the right auricle was immensely distended with fluid blood. The pericardium contained about five ounces of clear serous fluid. The intestines were not inflated; they contained a small quantity of thin, straw-colored, pasty substance. The color of the jejunum, as it lay in situ, was a beautiful faint rosy tint. The ileum and colon were more darkly congested. The mucous surface of the alimentary canal presented no other sign of disease, except that the solitary glands of the cæcum were remarkably conspicuous, some of them being nearly as large as a mustard-seed. The stomach presented nothing unusual. The spleen was not enlarged; its substance was firm and of a dark slate-color. The kidneys appeared to be perfectly healthy. There was no serous accumulation within the cavity of the peritoneum. The liver was full of fluid blood, which followed the knife profusely; its color was darker than normal, but not so dark as the spleen; the gall-bladder was filled with liquid yellowish-green bile. The blood was uncoagulated in the veins of the arm, as well as in those of the neck and throughout the viscera.—Acting Assistant Surgeon H. M. Lyman.* Hospital No. 2.

CASE 777.—Private Henry Fay, company F, 51st Illinois volunteers; age 21; five feet nine inches and a half high, dark complexion, gray eyes, brown hair; admitted October 2, 1862. Chronic diarrhœa. The patient was much emaciated and debilitated; his bowels were disturbed as often as once an hour; the evacuations were rather small, containing blood and mucus, and were attended with much tormina. He expressed a great desire for cold drinks. His skin was dry and of a dusky hue, the surface cool, particularly the extremities; the tongue was dark brown in the center, and bright red and dry at the tip and along the sides; the pulse about 110, small and hard; respiration was natural, and the sensorial functions were unimpaired. ℞. Calomel six grains, opium three grains, ipecacuanha six grains; make four powders. Take one every three hours. Also, ℞. Sulphate of morphia two grains, tannin ten grains, mucilage two ounces. Give a tablespoonful by injection after each evacuation. Diet: Boiled rice and milk. October 3d: The evacuations are less frequent and attended with less tormina; pulse 105; other symptoms about the same as yesterday. Treatment and diet continued. October 4th: Slept well last night; seems better this morning; evacuations less frequent, color and quality more natural; tongue not so dark, tip and edges still very red; pulse 100, with a little more volume. The abdomen continues tender on pressure. Stop medicines and substitute the following: ℞. Brandy and water of each three ounces, tincture of opium one drachm, tannin ten grains, oil of cinnamon five drops. Take half an ounce every two hours. Diet as before. October 5th: Feels better; slept well; abdomen less painful; evacuations still thin and watery but less frequent; tongue the same as yesterday. Diet and treatment continued. October 6th: Is much worse this morning; evacuations very frequent, small, consist of blood and mucus, and are attended by severe tormina; abdomen very tender, particularly in the hypogastric region; tongue dry and black in the center; sensorial functions unimpaired; prostration extreme. Treatment: ℞. Brandy six ounces, water four ounces, tincture of opium a drachm and a half, creasote five drops, oil of cinnamon five drops. Take an ounce every two hours. Injections continued. Diet: Essence of beef, boiled rice and milk. October 8th: Had a very restless night; bowels moved as often as every half hour, and toward morning even more frequently;

* Dr. LYMAN has published this case in the *Amer. Med. Times*, Vol. V, August, 1862, p. 110, as a case of congestive fever.

evacuations small, and consist almost entirely of blood. Stomach irritable, vomits occasionally; pulse very small and rapid; skin dusky and cold, especially the extremities; eyes sunken; sordes accumulating on the teeth, gums and lips; abdomen very tender and concave. Died, October 10th. *Autopsy* twenty hours after death: Body extremely emaciated; rigor mortis imperfectly developed; the surface was dusky, excepting along the course of the linea alba, where it was livid; no ecchymosis or purpura. Brain not examined. There were old pleuritic adhesions laterally and posteriorly on both sides, especially the left side. The lungs were normal, excepting a small part of the posterior portion of each lung, which was of a purplish hue from hypostatic congestion. The pericardium contained nearly an ounce of serum. The heart was normal. The stomach was inflated with gas; the color and consistence of its mucous membrane were natural. The spleen was enlarged, soft, and easily broken down with the finger. The liver was slightly enlarged and congested; the gall-bladder contained about an ounce of unhealthy bile. The duodenum was healthy. The upper portion of the jejunum was natural, its middle portion congested, the lower part inflamed. The ileum was highly inflamed throughout, and Peyer's glands were extensively ulcerated; the ulcers were deep and well defined, perforating the mucous coat, and surrounded by a dark-purple or almost black border. The ileo-cæcal valve was extensively ulcerated and of a dark color, almost black. The cæcum was highly inflamed but not ulcerated. The ascending colon was much inflamed, its upper portion ulcerated; the transverse colon very much inflamed and extensively ulcerated; the descending colon in much the same condition as the transverse. The sigmoid flexure and rectum were not opened. The omentum contained no fat, was much inflamed, its vessels greatly enlarged and filled with blood; the mesentery was in the same condition. The mesenteric glands were much enlarged, some of them measuring ten lines by seven. The kidneys were normal.—Assistant Surgeon Jas. F. Weeds, U. S. A. Hospital No. 4.

CASE 778.—Private Tobias Duell, company E, 19th United States Infantry; admitted October 10, 1862, with jaundice. Died, October 16th, of chronic diarrhœa. *Autopsy* fourteen hours after death: The integuments over the abdomen were livid; rigor mortis complete. There were extensive pleuritic adhesions on both sides; large tubercular deposits in the apex of the left lung; hypostatic congestion in the apices of both lungs. The heart was normal; in the left ventricle a fibrinous clot about an ounce in weight adhered to the aortic valves. The liver was bound to the diaphragm by firm old adhesions; the gall-bladder contained about an ounce of unhealthy bile. The substance of the liver was normal. The omentum contained no fat. The spleen and kidneys were normal. The upper portion of the ileum was considerably inflamed; in its middle portion there was a single well-defined ulcer. The rectum was dotted with numerous small ulcers. The mesenteric glands were enlarged and tuberculous.—Hospital No. 4.

CASE 779.—Private William B. Calkins, company E, 1st Michigan engineers and mechanics; age 37; lymphatic temperament; admitted September 2, 1862. Chronic diarrhœa. Treatment: Tonics, stimulants and astringents, with as good diet as the hospital could afford. Died, September 21st. *Autopsy:* Body extremely emaciated. The right lung was firmly adherent to the ribs and diaphragm; the left lung was normal. The pericardium contained two ounces of serum. The heart was of natural size, its left ventricle empty, the right ventricle contained a large firm polypus-like coagulum; the mitral valve was much thickened. The stomach was very small and contained two ounces of a brown extremely offensive fluid. The liver was apparently normal; the gall-bladder filled with dirty colored bile. The pancreas and spleen were normal. The mesenteric glands were somewhat enlarged. Evidences of inflammation were found in the ileum and colon; in the latter there were some gangrenous spots. The mucous membrane of the cæcum was abraded in some places, and of a dark almost black color. The kidneys, ureters and bladder were normal.—Hospital No. 6.

CASE 780.—Sergeant Thomas Powers, company E, 24th Kentucky volunteers; age 37; admitted September 19, 1862. Chronic diarrhœa. This man had frequent stools, with extreme tormina and tenesmus; his pulse was feeble and frequent; respiration hurried; tongue coated with a brownish fur; stomach irritable; urine of a deep-red color. He was but moderately emaciated and his mind was clear. Treatment: Tonics, stimulants, anodynes, counter-irritation to the abdomen, and nourishing diet. He died, October 3d, of asthenia. *Autopsy:* Body moderately emaciated; skin of a brownish tint. There were no pleuritic adhesions, and the lungs were normal with the exception of a calcareous nodule the size of a bean which was found in the middle lobe of the right lung. The pericardium contained an ounce and a half of serum. The heart and its valves were normal; both ventricles were empty; the auricles contained a small quantity of black and semi-fluid blood. The liver was large and pale, its texture firm; the gall-bladder contained a little bile. The stomach was elongated, and contained six ounces of a yellowish fluid of the consistency of syrup; its mucous membrane was of a dark liver-color, with excoriations toward the cardiac extremity; near the pylorus there were three deep ulcers two and a half to three lines in diameter. The duodenum, jejunum and upper portion of the ileum were normal; the mucous membrane of the lower portion of the ileum was red and thickened. The mucous membrane of the ascending colon was of a dark purple color and thickened; this condition extended to the transverse and descending colon, but diminished in degree toward the sigmoid flexure, where the mucous membrane again became healthy. The spleen was large; its color normal, its texture firm. The kidneys were normal. The pancreas was very large.—Hospital No. 6.

CASE 781.—Private Henry Thorncroft, company B, 15th United States Infantry; admitted October 3, 1862. Chronic diarrhœa. This patient had been sick about eight months. He was extremely emaciated; his temperature low, coldest in the extremities; his features contracted; pupils dilated; voice husky; his skin brown and shrivelled; pulse 48; respiration occasionally sighing; urine scanty and never passed without a discharge from the bowels; stools frequently involuntary. Treatment: Diffusible stimulants, wine whey, mucilaginous drinks, astringents, tonics, generous diet, frictions to extremities, warm applications to extremities and abdomen. Died, October 14th. *Autopsy* ten hours after death: Height five feet five inches; body very much emaciated. There were extensive old pleuritic adhesions on the right side. The lungs were normal. The pericardium contained an ounce and a half of serum. The heart was rather small; its left ventricle empty and contracted. The liver was large, extending into the left hypochondrium; its under surface was lead colored, its upper surface presented a number of yellowish spots the size of a dime; the gall-bladder was distended with bile. The spleen was large and soft. The omentum was small and dirty looking; its vessels engorged. There were some peritoneal adhesions. The mesenteric glands were enormously

enlarged. The pancreas was tough, dry and hard to cut. The stomach contained six ounces of dark-brown fluid, the appearance of which indicated an admixture of bile. The mucous membrane of the stomach, in both upper and lower curvatures, presented ecchymosed spots of a dark-purple color; the pyloric extremity of the stomach was normal. The mucous membrane of the small intestine was normal, except in the neighborhood of the ileo-cæcal valve, where it was ulcerated. The blood-vessels of the colon were much injected; its mucous membrane was full of ulcerations, and in patches gangrenous and sloughing. The kidneys were normal.—Hospital No. 6.

Case 782.—Private Baylor H. Sherrill, company E, 13th Kentucky volunteers; age 27; admitted September 2, 1862. Chronic diarrhœa. The patient was very much debilited by the continued discharges from the bowels. For a time the use of tonics and stimulants, together with astringents, seemed to improve his condition; but shortly after the 1st of October a change for the worse took place, and he died October 18th.—Acting Assistant Surgeon Thomas Hughes. *Autopsy:* Body very much emaciated. Height five feet eleven inches. The thoracic viscera were normal, except that the pericardium contained three ounces of serum. The liver was large; its anterior edge dark colored, its texture normal. The spleen was normal. The stomach contained from four to six ounces of a greenish-yellow slimy fluid; its mucous membrane was healthy in appearance with the exception of a few patches, some of a cinnabar red, others of a dark-blue color toward the larger curvature. The mucous membrane of the small intestine showed no traces of morbid alteration. The mucous membrane of the ascending and transverse colon was also natural; the descending colon was very much contracted, being only the size of the middle finger. The lower part of the sigmoid flexure was dark blue; its mucous membrane and that of the rectum was ulcerated and presented numerous gangrenous spots the size of a half dime. The ileum contained very little mucus. The transverse colon contained an ochre-colored fluid of the consistence of thin syrup. The mesenteric glands and the kidneys were normal.—Surgeon Charles Schüssler, 6th Indiana volunteers. Hospital No. 6.

Case 783.—Private Bartley Murphy, company K, 10th Kentucky volunteers; age 30; admitted September 26, 1862. Dysentery. His pulse was small and frequent; tongue furred in the middle, red on the tip and edges; stomach irritable; urine highly colored; emaciation considerable but not extreme. He died October 21st. This man had a low adynamic fever from the time he entered the hospital. Singultus set in about two weeks before death, and continued with intermissions until he died. An antiphlogistic and antifebrile plan of treatment was pursued. *Autopsy:* The body was greatly emaciated. Height five feet ten inches. The chest presented a number of ecchymosed spots, particularly on the left side, commencing a little above the nipple and extending to the false-ribs and the scrobiculus cordis. The lower lobe of the left lung was strongly adherent to the diaphragm; on the surface of the lung there were a number of dark lines corresponding in shape with the ribs; the upper lobe was hepatized, the lower lobe healthy; the right lung was normal. The pericardium contained about two ounces of serum. The left ventricle of the heart was empty; the left auricle contained black coagula; the right ventricle was empty; the muscular walls, especially those of the right ventricle, were soft, pale and fatty. The liver was rather large and pale; its upper surface was adherent to the diaphragm; the gall-bladder was full of bile. The spleen was normal. The stomach was enormously large, but presented nothing remarkable excepting its size. The small intestine was normal. The colon was highly inflamed throughout the greater portion of its length. The kidneys and bladder were normal.—Hospital No. 6.

Case 784.—Private Solomon Wood, company I, 1st Michigan volunteers; age 43; admitted October 20, 1862. Chronic diarrhœa. When admitted the patient had frequent slimy evacuations accompanied with tenesmus. He had a sullen sleepy appearance, spoke but little, and remained in bed in a somnolent state from which he could easily be roused. His abdomen was tender on pressure. He was moderately emaciated; pulse 60, full but compressible; respiration normal. In the treatment turpentine emulsion, mercury and chalk combined with Dover's powder, nitrate of silver in pills, &c., were administered by the mouth, and a solution of nitrate of silver used by enema, but without checking the disease. He died October 29th. *Autopsy* ten hours after death: Body moderately emaciated; skin yellowish. Height five feet five inches. The right lung was normal; its upper lobe was slightly adherent to the pleura costalis; there were no pleuritic adhesions on the left side; the left lung was hypostatically congested. The larynx, trachea and bronchial tubes were normal. The pericardium contained half an ounce of serum. The heart and its valves were normal. The arch of the aorta was unusually large. The liver was normal; the gall-bladder distended with bile. The spleen was large, soft and dark colored. The stomach was enormously distended with gas and contained a pint of dark greenish fluid; its mucous membrane was normal. The ileum presented marks of inflammation, its mucous membrane being tumid, especially near the ileo-cæcal valve, and ulcerated in many places. The mucous membrane of the large intestine was of a dark greenish color, and presented many ulcerations and gangrenous patches. The ascending colon was agglutinated to the omentum in such a way as to form several sacs filled with a yellowish turbid fluid. The mesenteric glands were enlarged. The kidneys, ureters and bladder were normal.—Hospital No. 6.

Case 785.—Private Samuel D. Case, company D, 51st Indiana volunteers; age 42; admitted October 12, 1862. Chronic diarrhœa. No previous history was obtained. When admitted the patient had profuse diarrhœa; his pulse was feeble and thread-like, from 98 to 100; the respiration slow but normal; the tongue red and clean; the urine pale. Most of the time the patient lay quietly on his left side. His skin was dry, cold, and stretched over the facial bones, giving him a cadaverous appearance. His abdomen was slightly distended; his feet œdematous. He had no appetite and was extremely prostrate. Treatment: Astringents, anodynes, stimulants and tonics, with a nourishing diet. Died, November 1st. *Autopsy* fifteen hours after death: Body extremely emaciated. The feet and ankles were œdematous; the skin yellowish-brown and parchment-like. The surface of the upper lobes of both lungs was emphysematous. The pericardium contained four ounces of serum. The heart was pale; the mitral valves thickened; the left cavities contained a good deal of dark blood of the consistency of syrup. The right lobe of the liver was strongly adherent to the diaphragm; the parenchyma of the organ was pale but otherwise normal; the gall-bladder contained a small quantity of bile. The spleen was rather small and of normal texture. Several portions of the omentum was thickened, discolored and very vascular. The stomach was very large, distended with gas, and contained a quantity of semi-transparent fluid; its mucous membrane was pale, and streaks of pus were attached to it in considerable quantity

in several places; near the pyloric extremity there was some ulceration. The ileum presented no evidences of disease except that it was much contracted in several places. The mucous membrane of the colon presented but little evidence of disease. About five inches from the ileo-cæcal valve there were several excoriations, but elsewhere it was pale and coated with a small quantity of watery mucus. The kindeys were normal.—Hospital No. 6.

CASE 786.—Private John Meister, company I, 1st Wisconsin volunteers; age 50; admitted September 19, 1862. Chronic diarrhœa of six months' duration. When admitted this patient had frequent exhausting discharges from the bowels; his pulse was very feeble and frequent. He had some dyspnœa; his tongue was pale, considerably coated, and he had very little appetite. He was in a condition of extreme debility. The treatment consisted chiefly in the use of tonics and stimulants. As a tonic the following was ordered: ℞. Tincture of the chloride of iron one ounce, infusion of serpentaria nine ounces. Take a teaspoonful three times a day. Carbonate of ammonia, beef-essence and milk-punch were given regularly during the last three weeks of life. He died from asthenia, November 14th. *Autopsy* twenty hours after death: Five feet six inches high. Body moderately emaciated; feet œdematous. The heart was normal in size; the coronary veins were much engorged; the muscular tissue was in a state of incipient fatty degeneration; the right ventricle and the left auricle contained coagula; the mitral valve was thickened and discolored; the ascending portion and arch of the aorta were large. The liver was pale; the gall-bladder contained an ounce and a half of bile. The spleen was enlarged and dark, but firm. The pancreas was softened and of a dark-gray color. The stomach was large; its mucous membrane presented many excoriations and livid red spots. The mucous membrane of the ileum was tumid and discolored. At the ileo-cæcal valve were deep gangrenous ulcers which extended into the cæcum. In the mucous membrane of the colon there were large ulcers having a gangrenous appearance. The kidneys were normal.—Hospital No. 6.

CASE 787.—Private Gilbert Perry, company G, 1st Ohio artillery; age 28; admitted September 26, 1862. Chronic diarrhœa. This patient was extremely emaciated. His pulse was frequent, full, but compressible; respiration 25 to 30 per minute; tongue red but streaked with a white fur. The stools were watery, mixed with blood, extremely frequent, at times attended with tenesmus. The urine was scanty and passed with pain. The face was colorless; the abdomen exceedingly tender on pressure, particularly along the track of the colon. Various modes of treatment were tried without benefit, especially enemata intended to reach the ulcerated portion of the colon. A nutritious diet was employed, with cod-liver oil, iron and stimulants. Died, November 20th. *Autopsy* fifteen hours after death: Body extremely emaciated. The lobes of the right lung were interadherent; the upper lobe collapsed; the middle and lower lobes presented on their surface a number of elevated spots the size of a silver dollar, hard at their peripheries, soft in their centers; the bronchial tubes leading to them were obstructed; in the upper lobe of the left lung similar isolated circumscribed elevations were found; the lower lobe was partially hepatized. The heart was of normal size; the right ventricle was empty, the left contained some dark fluid blood; the tricuspid valves were thickened, and the auriculo-ventricular opening narrowed; the mitral valves were also thickened and did not close fully, thus permitting regurgitation. The stomach was normal. The liver was highly engorged with blood; the gall-bladder was full of bile. The spleen was enlarged and softened. The duodenum and jejunum were normal. The lower portion of the ileum was reddened, its mucous membrane tumefied, and in several places much discolored. Throughout the whole length of the large intestine the mucous membrane was diseased and presented many deep ulcerations, some circumscribed, others confluent; there were also a number of red velvet-like tracts of considerable size, and some spots which appeared to be gangrenous. The kidneys were large but presented no abnormal appearance. The urinary bladder contained a considerable quantity of urine.—Hospital No. 6.

CASE 788.—Private Jefferson Waits, company B, 86th Illinois volunteers; age 27; admitted November 15, 1862. Diarrhœa and heart disease. At the time of admission he made no special complaint, but expressed himself as suffering from great fatigue, lassitude and chilliness. He said he had been nearly a year in the service and had not been sick much. On being questioned he admitted that he had diarrhœa, and that for several years he had been repeatedly troubled with a cough and pain in the chest. His pulse was small and irregular, both as to the force of the beats and the duration between; respiration was normal in frequency, but interrupted by irregularities between inspiration and expiration; the tongue was red but moist; the urine copious and pale. He was moderately emaciated. There was no change in his appearance until the morning of the 24th, when he complained of feeling cold and feared he was going to have a chill. In the course of the morning, while returning from the privy, he fell over on the floor and breathed his last in a few minutes. He had all along been able to walk about the room, taking his meals in the dining-room up stairs. The treatment had been addressed mainly to his bowels, and consisted in the use of turpentine emulsion, a diarrhœa mixture containing laudanum and tincture of lavender, sulphate of quinia in repeated doses, a nourishing diet and some stimulants. *Autopsy* ten hours after death: Body moderately emaciated. Height five feet four inches. There were pleuritic adhesions on both sides. The pericardium contained four ounces of serum. The heart was large and flabby; the left ventricle greatly enlarged, its walls thickened; the mitral valves insufficient and much thickened; the left auricle was very much dilated, and the auriculo-ventricular opening was very large, evidently allowing regurgitation; the right ventricle and auricle were also much dilated, and the walls of the ventricle thickened. The liver, spleen and kidneys were normal. The mucous membrane of the stomach presented many red spots, which, toward the cardiac extremity, were of a livid purple color. The mucous membrane of the ileum also presented spots of red discoloration; that of the colon was of a dark color and tumefied.—Hospital No. 6.

CASE 789.—Private George Stofer, company I, 19th Ohio volunteers; age 21; lymphatic temperament; admitted September 19, 1862. Consumption. When admitted this patient had a quick, small, wiry pulse, and frequent short respiration. He was extremely emaciated, his features sharp, chest narrow, and abdomen retracted. He had all the usual symptoms of consumption, but complained chiefly of the accompanying diarrhœa, which was troublesome and persistent. The treatment consisted principally in the use of supporting measures. Dry cups and rubefacients gave temporary relief to the pain in the right side, which troubled the patient a good deal. The diarrhœa was treated with turpentine emulsion, astringents, &c. Stimulants and cod-liver oil were administered freely. He died November 29th. *Autopsy* eighteen hours after death: Body greatly emaciated. The lungs, pericardium and heart were glued together into a mass by firm adhesions, which were interspersed with tubercles

of all sizes; both pleural cavities contained between the adhesions a considerable quantity of serum. The mucous membrane of the bronchial tubes was reddened, but this condition did not extend above the bifurcation of the trachea. Very little of the lung-tissue was permeable to air, both lungs being full of tubercles in all stages, and containing numerous cavities, mostly filled with pus or a thick rose-colored muco-pus; some of the cavities were small, others large and sinuous; generally one or more bronchial tubes opened into them; one of the cavities had opened into the left pleural sac. The heart was small and all its valves were normal. The liver, spleen, kidneys and stomach were normal. The mesenteric glands were enlarged. The intestines, contrary to expectation, presented very little pathological change beyond some redness of the lower part of the ileum. The ileo-cæcal valve and the colon were apparently normal.—Hospital No. 6.

CASE 790.—Private William B. Armstrong, company E, 86th Illinois volunteers; age 47; was admitted November 15, 1862, with bronchitis and chronic diarrhœa. He had been sick some time before admission. His pulse was frequent and feeble; respiration hurried; tongue tremulous, red and moist. He had frequent passages accompanied with pain and tenesmus, and was much debilitated. His face was pale, features sharp, abdomen distended. He admitted having been a hard drinker. There was dulness on percussion on the right side of the chest, and the right hypochondriac region was much distended. Under treatment he rallied somewhat, was able to be about, and asked permission to visit his regiment, distant about two miles, for the purpose of attending to some important business. He returned November 20th, complaining of a sense of constriction across the chest, became delirious, and died November 30th. Treatment: Alteratives, local revulsives, expectorants and tonics. *Autopsy* eight hours after death: Body moderately emaciated. The upper lobe of the right lung was emphysematous, the lower lobe hepatized gray; the left lung was much engorged with blood. The bronchial tubes were inflamed. The pericardium contained a pint of serum. The mitral valve of the heart was insufficient, the left ventricle was empty, the left auricle filled with black coagulated blood; the right ventricle contained much coagulated blood, the right auricle a well-washed fibrinous clot. The liver was large, pale, and presented the nutmeg appearance; it weighed six pounds and a half. The mucous membrane of the stomach was inflamed. In the lower third of the ileum there was an intussusception twenty inches long. The spleen was soft and larger than normal. The kidneys were large. The colon presented no abnormal appearance.—Hospital No. 6.

CASE 791.—Private Amos Mann, company E, 30th Indiana volunteers; age 21; admitted October 8, 1862. Chronic diarrhœa. This man had been sick for some time under the care of a private family near Nashville. His pulse was small and extremely frequent; his respiration hurried, and he had a short hacking cough. His tongue was pointed, red in front, furred toward its base. He was so much emaciated as to be almost a living skeleton. He had a severe diarrhœa, a craving appetite, and an extremely irritable disposition. The treatment was tonic and palliative. He died December 1st. *Autopsy* fifteen hours after death: The right lung was partially collapsed and contained a large quantity of black pigment; when cut into a quantity of pus exuded; a still greater quantity exuded when the left lung was cut into, and in its lower lobe there was a large cavity containing pus. The pericardium contained a small quantity of serum. The heart and its valves were normal. On opening the stomach a firm tumor the size of a hazel-nut, with a central opening from which pus flowed, was seen near the pylorus. The mucous membrane was inflamed and tumid. The mucous membrane of the ileum was also inflamed, and ulcerated about the ileo-cæcal valve; Peyer's glands were thickened. The mucous membrane of the colon was inflamed and ulcerated throughout. The spleen was enormously enlarged, weighing three pounds and a half. The liver was enlarged and congested; on cutting it the blood which exuded was mingled with bile; the gall-bladder was small and empty. The mesenteric glands were enlarged. The kidneys were small but normal in appearance.—Hospital No. 6.

CASE 792.—Private Marion Garrison, company F, 51st Illinois volunteers; age 32; admitted October 20, 1862. Chronic diarrhœa and pneumonia. This patient had been sick for several weeks; has not had the cough and dyspnœa so long. He is moderately emaciated; pulse 100 and full; respiration 30 and very difficult; cannot speak above a whisper; expectorates peculiar green sputa; tongue covered with a thick white coat, red at the edges; bowels moved about once every hour; urine apparently normal; countenance anxious. There is dulness on percussion, and bronchial respiration on the right side of the chest. To take a grain each of calomel and opium every four hours, alternated with three grains each of camphor and carbonate of ammonia and two grains of ipecacuanha. A blister to the right side of the chest. Died, October 25th. *Autopsy* twelve hours after death: Height five feet nine inches and a half. Right lung in the third stage of inflammation, (purulent infiltration;) left lung normal. The pericardium contained about six ounces of serum; the portion reflected over the heart was straw colored and very soft; the muscular structure of the heart was deeply congested. The small intestine was normal. The mucous membrane of the colon and rectum was ulcerated. The mesenteric glands were enlarged.—Assistant Surgeon A. C. Wedge, 3d Minnesota volunteers. Hospital No. 14.

The next nine cases are from the case-book of HOSPITAL No. 8, Nashville, Tennessee, Surgeon William C. Otterson, U. S. V., in charge at the date of the first case; Surgeon R. R. Taylor, U. S. V., till October 3, 1864; afterward Assistant Surgeon J. A. Freeman, U. S. V.:

CASE 793.—Private John W. Dougherty, company L, 1st Wisconsin cavalry; admitted February 17, 1864. This man came into hospital suffering with chronic diarrhœa, of which he got better, but was attacked with pleuro-pneumonia February 29th. Treatment: Counter-irritants to the chest, stimulants and expectorants. Died, March 8th, at 7 A. M. *Autopsy:* The brain was not examined. The heart was normal. The right lung was firmly bound to the walls of the chest by old and strong adhesions. The left pleural sac contained about two pints of turbid fluid; the left lung was coated with recent lymph, which was easily peeled off; when cut into there exuded a reddish frothy fluid; the lung-tissue was soft and readily crushed between the fingers. Nothing abnormal was detected in the abdominal viscera.—Acting Assistant Surgeon Chas. C. Shoyer.

CASE 794.—Private Robert R. Denman, company E, 9th Michigan cavalry; age 30; admitted February 16, 1864. Chronic diarrhœa. [This man appears upon the register of hospital No. 4, Knoxville, Tennessee, admitted January 4, 1864—

chronic diarrhœa; no disposition recorded.] The patient stated that he had suffered from diarrhœa since the middle of September last; has also been troubled a great deal with piles; is very greatly emaciated; complains of cold feet. ℞. Opium one scruple, sulphate of quinia two scruples, sulphate of copper ten grains, ipecacuanha five grains; make twenty pills. Take one every four hours. Cod-liver oil to be rubbed freely over the abdomen and chest three times daily. Milk diet, milk-punch, hot toddy, warming-pan to the feet, &c. This treatment was continued with no important variation until March 6th, when he was attacked with measles. Died, March 8th, at 11 A. M. *Autopsy* twenty-three hours after death: Body of medium size, greatly emaciated. There were old, very firm pleuritic adhesions on the right side; the right lung was greatly engorged but crepitant; the lower portion of the lung contained numerous miliary tubercles; there were no pleuritic adhesions on the left side; a small portion of the upper lobe of the left lung was in the stage of gray hepatization; miliary tubercles were scattered throughout the lung. The heart was small and flabby. The liver was cirrhosed, pale, and very firmly adherent to the abdominal walls and the diaphragm; it could only be removed by careful dissection. On microscopical examination the hepatic cells were found to present the appearances of fatty degeneration. The mesenteric glands were enlarged. The mucous membrane of the large intestine and rectum was extensively ulcerated. The spleen and kidneys were apparently normal.—Acting Assistant Surgeon A. T. Johnson.

CASE 795.—Private Ausburn Cooper, company G, 89th Ohio volunteers; admitted March 12, 1864. Chronic diarrhœa. This patient was first seen by the reporter March 25th. At that time he had cough and complained of pain in the left side; his skin was hot and dry; his pulse full. There was dulness on percussion over the lower portion of the left lung. Tartar emetic in small doses was prescribed during the first day, and on the second calomel was combined with it. Under this treatment the pulse became less frequent and full, the skin moister, and the patient breathed more easily. On the afternoon of March 27th he complained of feeling drowsy and dull, said he had difficulty in collecting his thoughts, and was troubled by disagreeable dreams when he slept; his mind, however, seemed clear. Died suddenly, March 29th. *Autopsy* twenty hours after death: There was a large quantity of serum in each pleural cavity. The lower portion of the left lung was hepatized, partly red and partly gray; the lower lobe of the right lung was partially hepatized, the upper lobe congested. The pericardium contained two ounces and a half of serum. The heart was healthy. The liver had the nutmeg appearance. The spleen and kidneys were enlarged. Nothing abnormal was observed in the intestines.—Acting Assistant Surgeon L. A. Walton.

CASE 796.—Private William McGuire, recruit, 104th Ohio volunteers; admitted March 21, 1864. Diarrhœa and tonsillitis. The diarrhœa was treated with astringents and tincture of the chloride of iron; the tonsillitis with chlorate of potash internally and as a gargle. The patient was much depressed in spirits, and at all times insisted that he would die. He had twelve to fifteen loose passages daily. Subsequently he was attacked with pneumonia, which was treated on the supporting plan. Died, May 3d. *Autopsy* twenty-three hours after death: No rigor mortis. The brain was not examined. There were no pleuritic adhesions; each pleural sac contained about an ounce of serum. The lower lobe of the right lung was in the stage of gray hepatization. The heart was normal. The mucous membrane of the descending colon was thickened and congested.—Acting Assistant Surgeon Geo. E. Walton.

CASE 797.—Private Adam Schuyler, company D, 7th Pennsylvania cavalry; admitted April 22, 1864. Chronic diarrhœa. Treatment: A dose of castor oil and laudanum was given him on admission, and subsequently he took turpentine emulsion, camphor, opium and ipecacuanha in various proportions and combinations. Died, May 5th. *Autopsy* twelve hours after death: Rigor mortis marked. Brain not examined. The lungs were healthy. The heart was small but otherwise normal. There was considerable inflammation of the intestinal mucous membrane, especially in the ileum. The liver and spleen were healthy.—Acting Assistant Surgeon Jno. H. McIntyre.

CASE 798.—Private Thornton Hambright, company C, 2d East Tennessee cavalry; age 18; admitted April 20, 1864. Measles, followed by diarrhœa. This man was first seen by the reporter May 4th. He was then very feeble and emaciated; pulse quick; capillary circulation imperfect; fingers bluish and cold; scorbutic blotches upon the wrists. He had from seven to nine passages daily, which had a resemblance to pea-soup. He drank a great deal of water and his appetite was tolerable, but he vomited frequently. He expressed a great desire for fresh onions, which were supplied to him when possible. Prescribed ten drops of aromatic sulphuric acid every three hours and two teaspoonsful of Hope's mixture every two hours. Sherry wine. May 9th: Ordered, every two hours, a pill containing one-sixth of a grain of sulphate of copper and one-eighth of a grain of opium. May 11th: There were but two passages since yesterday morning. May 12th: Pulse 97; two passages. May 14th: Pulse 128. May 15th: Is evidently sinking. Died, May 16th, at 2 P. M. During the last two weeks of this man's life a peculiar harshness of voice was noticed. *Autopsy* twenty-five hours after death: No rigor mortis. The brain was normal. The mucous membrane of the larynx and trachea was of a black color, as though gangrenous, and evolved a very offensive odor. There were slight pleuritic adhesions and some hypostatic congestion of the posterior portion of the lower lobe of the right lung. The heart was normal; there was a black clot in the left ventricle, in the right a large white fibrinous clot, somewhat adherent to the columnæ carneæ, and extending into the pulmonary artery. The liver was normal; the gall-bladder contained but little bile. The kidneys were pale; the spleen normal. There were patches of congestion in various portions of the small intestine. [There is no record of the condition of the large intestine.]—Acting Assistant Surgeon Geo. E. Walton.

CASE 799.—Corporal Ezekiel Porter, company C, 81st Indiana volunteers; age 24; admitted June 11, 1864. Chronic diarrhœa. [This man appears upon the register of the Chattanooga hospital, Tennessee, admitted from his regiment May 24th—neuralgia—sent to Nashville June 10th.] When admitted he had hiccough, frequent watery evacuations, and vomited after taking food. Treatment: Opiates and astringents; fomentations and blisters to the abdomen. Died, June 19th. *Autopsy* twenty-four hours after death: There was inflammation of the mucous membrane of the stomach and almost the whole extent of the small intestine. The other viscera were not examined.—Acting Assistant Surgeon William Herbert.

CASE 800.—Private John W. Burris, recruit, 71st Ohio volunteers; age 25; admitted November 23, 1864. Chronic diarrhœa. [This man appears on the register of the field hospital of the 3d Division, 4th Corps, admitted November 15th—

measles—sent to general hospital November 22d.] At the time of admission he was much emaciated; his tongue and teeth covered with sordes; he had no appetite; very frequent passages from the bowels, attended with pain and tenesmus; pulse frequent and feeble; tongue tremulous on protrusion; conjunctivæ injected. Treatment: Tannin, opium, stimulants, &c. Died, November 25th, at 1 P. M. *Autopsy* twenty hours after death: Thoracic viscera normal. The duodenum, jejunum and upper third of the ileum were healthy; the lower two-thirds of the ileum were highly injected; the solitary glands enlarged; one Peyer's patch was ulcerated. Near the ileo-cæcal valve were four or five old ulcerated but cicatrizing points. The mucous membrane of the cæcum was also congested and thickened; that of the colon was much thickened, of a pinkish color alternating with gray, and extensively ulcerated. The rectal mucous membrane was much thickened and covered with patches of effused blood.—Acting Assistant Surgeon H. C. May.

CASE 801.—Private Alexander McGannon, company K, 40th Illinois volunteers; age 20; admitted November 20, 1864. Chronic diarrhœa. [This man appears upon the register of hospital No. 1, Chattanooga, Tennessee, admitted November 14th—acute diarrhœa—sent to general hospital November 19th.] The patient was much emaciated; his countenance pale and anxious. He had very frequent watery passages, attended with pain and tenesmus; occasionally they were bloody, sometimes involuntary. There was retention of urine. Treatment: Small doses of opium, laudanum enemata, milk thickened with browned flour; warm fomentations to the abdomen. Died suddenly, November 27th, at 1 P. M. *Autopsy* twenty-four hours after death: Body rigid and extremely emaciated. Head and thorax not examined. The upper two-thirds of the small intestine were healthy; throughout the lower third the mucous membrane was congested in patches, and the solitary glands were enlarged. For twelve inches above the ileo-cæcal valve the surface was coated with yellow granular lymph. The cæcum was intensely congested, at some points ulcerated; its mucous membrane was of a dark coffee-color, that of the colon and rectum slate-color. All the coats of the colon were much thickened and indurated; it was extensively ulcerated, the ulcers extending through to the peritoneum, which was easily torn with the finger-nail. In the transverse colon were two perforated points half an inch in diameter, from which berry-seeds and other contents of the bowels had escaped into the abdominal cavity.—Acting Assistant Surgeon H. C. May. [Nos. 510 to 513, Medical Section, Army Medical Museum, are from this case. No. 510 is from high up in the ileum; No. 511 from near its middle; No. 512 from its lower extremity, including the ileo-cæcal valve. In each of these pieces the solitary follicles are enlarged to the size of pin-heads. In 511 and 512 a moderate quantity of pseudomembrane adheres to the mucous surface, and in 511 there is a large smooth cicatrix corresponding in size and position to a Peyer's patch. No. 513 is a portion of the descending colon, presenting a number of follicular ulcers, some of which have acquired considerable size; shreds of pseudomembrane are adherent to the mucous surface between the ulcers.]

The next twelve cases were forwarded on special reports* from HOSPITAL No. 19, Nashville, Tennessee, Surgeon W. H. Thom, U. S. V., in charge:

CASE 802.—Private Adam Hose, company I, 76th Ohio volunteers; admitted February 2, 1864. Chronic diarrhœa. [This man appears on the hospital register of his regiment, admitted January 1st—diarrhœa; no disposition.] Died, February 5th. *Autopsy* twenty-four hours after death: Rigor mortis slight; body extremely emaciated. There was an ounce of serum

in the subarachnoid space, and the pia mater was slightly injected; the brain was healthy in other respects and weighed forty-five ounces and a half. There were slight pleuritic adhesions on both sides; the lungs weighed together thirty-four ounces. The heart weighed five ounces and a half; its right auricle and ventricle contained large fibrinous clots; the veins contained a small quantity of fluid blood. The liver weighed forty-eight ounces; the spleen eight and a half; the two kidneys ten ounces; all these organs appeared to be healthy. The mucous membrane of the stomach and small intestine was thickened and softened; that of the large intestine was also thickened, softened and ulcerated throughout its whole length.—Acting Assistant Surgeon James E. Marsh.

CASE 803.—Private Henry Kohntopp, company G, 59th Illinois volunteers; age 34; admitted from his regiment January 28, 1864. Chronic diarrhœa of three months' duration and acute bronchitis. Died, February 6th. *Autopsy* twelve hours after death: Rigor mortis well marked; body slightly emaciated. The brain was healthy and weighed forty-nine ounces and a half. There were strong pleuritic adhesions posteriorly on both sides. The bronchial tubes were inflamed and filled with frothy mucus. The lungs weighed together thirty-one ounces and a half. The pericardium contained six drachms of serum. The heart weighed five ounces and a half. The liver weighed forty ounces; the spleen seven; the kidneys together twelve. The stomach was healthy. The mucous membrane of the large intestine was thickened, softened and ulcerated. The bladder contained six ounces of urine.—Acting Assistant Surgeon T. H. Hammond.

CASE 804.—Private Joseph Buchanan, company A, 51st Indiana volunteers; admitted December 21, 1863. Chronic diarrhœa. [This man appears on the register of hospital No. 13, admitted December 18th—chronic diarrhœa—sent to general hospital December 21st.] At the date of admission the patient was very thin, his skin dry and furfuraceous, tongue smooth and moist, appetite tolerably good, no fever. He had tenderness on pressure over the abdomen generally, and had about six operations daily, which were very thin and of a pale-yellow color. The disease continued with slight variations until three days before death, when fever, with urgent thirst and more frequent evacuations, set in and continued until death. Died, February 10th. *Autopsy* ten hours after death: Rigor mortis slight; body much emaciated. The brain was healthy and weighed forty-nine ounces and a half. The lower lobe of the left lung was hepatized; the remainder of the lungs was congested; they weighed together fifty ounces. The pericardium contained an ounce and a half of serum. The heart was healthy but small. The blood in the heart and in the great veins was dark and fluid. The abdominal cavity contained twelve ounces of straw-colored serum. The liver weighed forty-eight ounces; the spleen seven and a half; the kidneys nine. The stomach was healthy. The mucous membrane of the small intestine was somewhat injected. The colon was deeply congested and its lower portion ulcerated. The mesenteric glands were enlarged. The bladder contained eight ounces of urine.—Acting Assistant Surgeon K. J. Semple.

CASE 805.—Private S. P. Burdine, company E, 9th Tennessee cavalry; admitted from his regiment January 29, 1864. Dysentery and remittent fever. Died, February 11th. *Autopsy* twenty-four hours after death: Rigor mortis slight; no emaciation. The pia mater was slightly congested. The brain weighed fifty-five ounces and a half. There were slight pleuritic adhesions on the right side. The lungs together weighed thirty-four ounces; the heart ten and a half. The pericardium contained ten drachms of serum. The liver and spleen were softened; the former weighed sixty-four ounces, the latter ten. The kidneys together weighed ten ounces. The mucous membrane of the stomach was slightly inflamed; that of the small intestine was inflamed, thickened and softened in places; that of the large intestine was very much inflamed and thickened. The bladder contained an ounce of urine.—Acting Assistant Surgeon James E. Marsh.

CASE 806.—Private Robert S. Knox, company I, 34th Illinois volunteers; admitted January 25, 1864. Chronic diarrhœa. [This man appears upon the register of hospital No. 4, Chattanooga, Tennessee, admitted January 7th—chronic diarrhœa—sent to general hospital January 26th.] Died, February 11th. *Autopsy* six hours after death: Rigor mortis well marked; body emaciated. The brain was normal and weighed forty-eight ounces. The lungs together weighed forty ounces; the heart nine. The pericardium contained three drachms of fluid; the blood in the heart and great veins was fluid. The liver weighed fifty-one ounces; the spleen six; the right kidney nine, the left nine and a half. The mucous membrane of the stomach and small intestine was congested; that of the large intestine was thickened, softened and ulcerated. The bladder was empty.—Acting Assistant Surgeon S. F. Selby.

CASE 807.—Private Elias Hackley, company K, 123d Illinois volunteers; admitted January 9, 1864. Chronic diarrhœa. When first seen by the reporter, February 1st, his diarrhœa was much improved, but he was considerably emaciated, enfeebled, and had more or less gastric irritability; the latter symptom became aggravated before the termination of the case, and for three or four days preceding his death vomiting ensued immediately on taking any food into his stomach. Died, February 12th. *Autopsy* sixteen hours after death: Rigor mortis well marked; body much emaciated. The brain was healthy and weighed fifty-five ounces. There were pleuritic adhesions posteriorly on both sides. Tubercles were scattered through both lungs, and a mass of crude tubercles the size of a goose-egg was found in the middle of the left lung; the lungs together weighed forty ounces. The heart weighed eight ounces; the blood contained in it and in the great veins was fluid. The liver weighed forty-eight ounces; the spleen ten and a half. The kidneys were large, pale and softened; they weighed together eighteen ounces. The mucous membrane of the stomach was much inflamed and ulcerated at the pyloric extremity: that of the small intestine was also inflamed, especially the ileum. The large intestine was inflamed and ulcerated. The bladder contained ten ounces of urine.—Acting Assistant Surgeon Wm. Stemmerman.

CASE 808.—Private William A. Shell, company E, 13th East Tennessee cavalry; admitted February 1, 1864. Chronic diarrhœa. Died, February 13th. *Autopsy* fourteen hours after death: Rigor mortis moderate; body emaciated. The brain was healthy and weighed forty-nine ounces. The lungs together weighed forty-nine ounces. The pericardium contained half an ounce of fluid. The heart weighed nine ounces and a half; it contained coagula. The blood in the great veins was fluid.

The abdominal cavity contained about five ounces of serum. The liver weighed sixty-five ounces. The spleen weighed nine ounces. The kidneys together weighed ten ounces and a half. The mucous membrane of the stomach was injected and softened. The small intestine was distended with gas. The mucous membrane of the ileum and of the commencement of the large intestine was injected; that of the lower portion of the large intestine was softened and ulcerated. The bladder contained about eight ounces of urine.—Acting Assistant Surgeon S. F. Selby.

CASE 809.—Private George Seymour, company E, 15th United States Infantry; admitted January 27, 1864. Chronic diarrhœa. [This man appears on the register of hospital No. 4, Chattanooga, Tennessee, admitted January 11th—quotidian intermittent fever—sent to general hospital January 26th.] Pneumonia was developed a few days after admission, but was of a latent character, having no prominent symptoms that might not have been attributed to the diseased condition of the intestines. Died, February 16th. *Autopsy* ten hours after death: Rigor mortis moderate; body much emaciated. The brain was healthy and weighed forty-nine ounces and a half. The upper lobe of the right lung was pneumonified and adherent to the thoracic parietes; the lungs weighed together forty ounces. The heart was soft and flabby; it weighed seven ounces. The blood in the heart and large veins was dark and fluid. The abdominal cavity contained six ounces of serum. The liver weighed fifty-two ounces; the spleen eleven; the two kidneys eight. The mucous membrane of the stomach and small intestine was congested; that of the large intestine was deeply congested and thickened. The bladder contained four ounces of urine.—Acting Assistant Surgeon K. J. Semple.

CASE 810.—Private Henry Dugger, company E, 13th Tennessee cavalry; admitted February 7, 1864. Chronic diarrhœa and anasarca of the lower extremities. The patient remained in about the same condition until the 12th, when he was taken with cough, pain in the chest, dyspnœa and the usual symptoms of pneumonia. Died, February 19th. *Autopsy* eighteen hours after death: Rigor mortis slight; body emaciated. The brain was healthy and weighed fifty-one ounces. There were slight recent pleuritic adhesions on the left side. The lower lobes of both lungs were in a state of engorgement; the lungs weighed together fifty-nine ounces. The heart was healthy and weighed eight ounces; its right cavities contained large well-washed clots; the blood in the great veins was fluid. The liver weighed seventy-four ounces and a half; the spleen eight ounces; the kidneys together ten ounces and a half. The lower portion of the small intestine was injected. The lower portion of the large intestine was thickened and ulcerated; some of the ulcers were cicatrizing. The bladder contained about three ounces of turbid urine.—Acting Assistant Surgeon James E. Marsh.

CASE 811.—Private Levi Woodmansee, company E, 8th Indiana cavalry; admitted February 6, 1864. Chronic diarrhœa. February 22d, symptoms of peritonitis set in. Died, February 24th. *Autopsy:* The abdominal cavity contained pus. The peritoneum was coated with pseudomembrane. The mucous membrane of the intestines was similarly coated. The lower portion of the large intestine was ulcerated. The left kidney contained a number of calculi embedded in its pelvis and calyces; they were of various shapes and sizes and eighteen in number; they varied in weight from one to sixty-five grains, weighing in all a hundred and twenty-three grains.—Surgeon John W. Foye, U. S. V. [No. 593, Medical Section, Army Medical Museum, is from this case. The specimen consists of the calculi above described; they are composed chiefly of oxalate of lime mixed, however, with some phosphates.]

CASE 812.—Private Hiram Gregory, company I, 12th Kentucky volunteers; admitted February 12, 1864. Chronic diarrhœa. [This man appears on the register of hospital No. 2, Knoxville, Tennessee, admitted January 16th—typhoid fever—returned to duty [!] February 3d.] The patient was greatly emaciated, could not eat anything with appetite, and had all the symptoms of chronic bronchitis besides a persistent diarrhœa. Died, February 26th. *Autopsy* seventeen hours after death: Rigor mortis well marked; body much emaciated. The brain was healthy and weighed fifty-five ounces. The bronchial tubes were inflamed. The lungs weighed together fifty-five ounces. The heart appeared to be healthy; it weighed ten ounces and contained fluid blood. The pericardium contained an ounce of fluid. The liver weighed sixty-three ounces; the spleen nine ounces; the two kidneys sixteen ounces. The mucous membrane of the stomach was congested; that of both small and large intestines inflamed and ulcerated. The bladder contained five ounces of urine. Acting Assistant Surgeon Ezra Woodruff.

CASE 813.—Private Samuel Winkelpleck, 20th Ohio battery; admitted January 27, 1864. Chronic diarrhœa. [This man appears on the register of hospital No. 4, Chattanooga, Tennessee, admitted January 5th—chronic rheumatism—sent to general hospital January 26th.] Died, February 29th. *Autopsy* twenty-four hours after death: Rigor mortis slight; body not much emaciated. The brain was healthy and weighed forty-eight ounces. The lungs weighed together sixty-nine ounces; the posterior portions of the upper lobes of both were pneumonified. The heart weighed seven ounces; it was healthy, except that the walls of the right ventricle were somewhat thickened. The blood in the heart and veins was dark and fluid. The liver weighed sixty-two ounces; the spleen ten; the two kidneys twelve. The stomach was healthy. The mucous membrane of the small intestine was congested, thickened and in patches ulcerated. The lower portion of the large intestine presented numerous ulcers, some of which appeared to be cicatrizing. The urinary bladder was empty.—Acting Assistant Surgeon K. J. Semple.

The notes of the next case were forwarded, with the specimens, to the Army Medical Museum from HOSPITAL No. 3, Murfreesboro', Tennessee, Surgeon Israel Moses, U. S. V., in charge:

CASE 814.—Private Harry Myers, company H, 134th New York volunteers; admitted November 12, 1863. He had suffered from diarrhœa for six months; was much prostrated and greatly emaciated; his tongue was dry, and the discharges from the bowels were very frequent and profuse. During the first month he improved somewhat, and then began to run down. Died, December 30th. *Autopsy:* The solitary follicles of the ileum were enlarged. The colon and rectum were thickened and

ulcerated.—Assistant Surgeon W. E. Whitehead. [Nos. 197 to 200, Medical Section, Army Medical Museum, are from this case. Nos. 197 to 199 are successive portions of the ileum, exhibiting well-marked enlargement of the solitary follicles and some hypertrophy of the villi; the first and third pieces each present a large Peyer's patch, which, however, appears to be normal. No. 200 is a portion of the rectum, which exhibits a number of punched-out ulcers of the solitary follicles, several of which have extended into oval excavations of moderate size; irregular patches of pseudomembrane adhere to the mucous surface.]

The next four cases are from the TULLAHOMA HOSPITAL, Tennessee, Surgeon Benjamin Woodward, 22d Illinois volunteers, in charge:

CASE 815.—Private Eli Mangus, company F, 29th Indiana volunteers. [Date of admission not stated.] This man has been sick five months with chronic diarrhœa, for which, as he says, he took silver pills every four hours for four weeks, during which time he became a very dark color. At present the whole surface of his body is of a dark lead color, and he is much emaciated. Died, September 7, 1863. *Autopsy* twelve hours after death: The brain and its membranes, the heart and lungs were all normal. The liver was enlarged and clay colored. The small intestine was healthy. The large intestine presented large patches of ulceration. The mesenteric glands were greatly enlarged.—Surgeon Benjamin Woodward.

CASE 816.—Private John Sancrant, company G, 15th Michigan volunteers; admitted November 12, 1863. Diarrhœa. This man was brought from Elk river, where he had been sick a long time. No history of his case could be obtained, except that he had long suffered from ague. [He appears on the hospital register of his regiment, admitted September 29th—diarrhœa—returned to duty October 27th, and again admitted November 1st—acute peritonitis—sent to general hospital November 12th.] Died, November 17th, at 4 P. M. *Autopsy* eighteen hours after death: Body much emaciated. The whole of the small intestine was much inflamed. The transverse colon was gangrenous. The descending colon and rectum were extensively ulcerated. The kidneys were nearly double their normal size, and, when cut into, pus was found in all the calyces. The peritoneum presented numerous inflammatory patches and was much thickened. The spleen was at least five times its natural size, and very hard when cut. The mucous membrane of the bladder was very vascular.—Surgeon Benjamin Woodward.

CASE 817.—Private Hugh Montgomery, company K, 9th Iowa volunteers; admitted from Bridgeport, Alabama, November 31, 1863. This patient had suffered from chronic diarrhœa for several months and was very much emaciated. The stools were frequent and watery. A nutritious diet and stimulants were ordered. The diarrhœa was so far checked by treatment that there were but two or three dejections a day, but the patient gained no strength and gradually wasted away. His skin had from the first the peculiar bronzed appearance aseribed to Addison's disease. He died January 1, 1864. *Autopsy* eight hours after death: The thoracic viscera were normal. The liver and intestinal canal presented no evidences of disease. The spleen was about double the normal size. The kidneys were very much enlarged, hard, and, when cut open, had a peculiar waxy appearance. The suprarenal capsules were three times the usual size, and one of them contained a deposit which resembled tubercular matter but was harder than that deposit generally is; no tubercles were found elsewhere. The blood in all parts of the body was very thin.—Surgeon Benjamin Woodward.

CASE 818.—Private Francis M. Hunt, company G, 2d Kentucky cavalry; admitted October 26, 1863. Diarrhœa and gastritis. This man was said to have been sick a long time, but no connected history of his case could be obtained. The diarrhœa yielded to simple treatment, but the gastritis was unmanageable and increased in severity. The prominent features of his case were a moist red tongue, and uncontrollable thirst which nothing would allay. Food or the blandest drinks caused him to vomit, but the thirst was so pressing that if not closely watched he would drink anything within reach. He died February 9, 1864. *Autopsy* twenty hours after death, by Assistant Surgeon H. Pearce, 150th New York volunteers: The pyloric extremity of the stomach was highly inflamed and softened, but there was no ulceration; the limits of the inflamed portion were very distinct. [The condition of the intestines is not recorded.]—Surgeon Benjamin Woodward.

The next two cases were forwarded on medical descriptive lists from the CHATTANOOGA HOSPITAL, Tennessee, Surgeon Francis Salter, U. S. V., in charge:

CASE 819.—Private George D. Bates, company F, 11th Michigan battery; age 18; admitted March 15, 1864. Measles. The eruption in this case made its appearance March 12th; it has now partly subsided. The patient is of a scrofulous diathesis, and has severe bronchitis and diarrhœa. Ordered tonics and stimulants; light diet. March 20th: The diarrhœa continues. There is severe cough and muco-purulent expectoration. March 23d: The cough and diarrhœa continue. ℞. Mercury with chalk one scruple, ipecacuanha eight grains, opium three grains; make four powders. Take one every six hours. March 24th: The diarrhœa is better. The patient complains of hoarseness, and pain in the left shoulder. The cough continues, with some expectoration. Continue treatment. Apply volatile liniment to the shoulder. Beef-tea and wine. March 25th: The diarrhœa is again very troublesome; appetite poor; the cough is unchecked; the pain in the shoulder continues, and the right arm is paralyzed. The patient is very weak. To take ten drops of oil of turpentine in emulsion every three hours. Continue the other treatment. March 26th: The patient is about the same as yesterday, but rather weaker. He is unable to rouse himself; pulse 100, weak and compressible. Continue treatment, with free use of stimulants. March 29th: The diarrhœa is better. There is paralysis in the right leg as well as the right arm. Appetite poor. Continue treatment. March 31st: The diarrhœa is worse again, and the passages are numerous and very thin. He vomited a lumbricoid worm this morning. Is very weak. Discontinue the medicines. Give wine and milk-punch. April 2d: The back of the left hand is red and injected; the tongue dry, covered with a dark coat, and fissured; the right shoulder is swollen and painful; the diarrhœa continues. The patient picks at his nose and tongue; his respiration is rapid and feeble; pulse almost imperceptible. Died at noon. *Autopsy* twenty-four hours after death: Rigor mortis well marked. The membranes of the brain were injected; the brain-substance appeared

to be normal. The right pleural sac contained sixteen ounces of serum, the left pleural sac eight ounces. There were no adhesions, but the surface of the lungs was covered with unorganized lymph; the parenchyma of the lungs was healthy. The mucous membrane of the bronchial tubes was red, thickened and covered with a muco-purulent secretion. The heart was small but normal. The liver was large and white; on its superior surface there were three large white spots extending from one to three lines below the surface; the gall-bladder was full of dark colored bile. The stomach contained a quantity of dark bilious matter; its mucous surface was studded with small injected spots one or two lines in diameter, and of a blood-red color. The kidneys were large, between four and five inches long and three inches broad; there was no difference in color between the cortical and pyramidal portions; the suprarenal capsules were an inch and a half long and three-quarters of an inch broad. The mucous membrane of the large intestine was ulcerated throughout; the ulcers were largest and most numerous in the rectum, decreasing in size and number toward the ileo-cæcal valve. In the sigmoid flexure and below it there was not a square inch of mucous membrane free from ulcers; most of them had penetrated to the peritoneal coat, so that the gut gave way on the slightest tension; the ulcers were irregular in shape, with sharp well-defined edges, as if cut with a punch.—Acting Assistant Surgeon Thomas A. McGraw.

CASE 820.—Private Thomas Duke, company C, 38th Ohio volunteers; age 22; admitted April 12, 1864. Chronic diarrhœa. Is much debilitated; stools frequent; appetite poor. April 18th: Notwithstanding the free use of tonics, stimulants and good nutritious food, the patient is daily growing feebler. His passages are very thin and frequent; appetite poor. Died, April 20th. *Autopsy* twelve hours after death: The brain was anæmic; there was a large quantity of serum beneath the arachnoid, and one or two small patches of organized fibrin on the superior surface of the cerebrum. There were old pleuritic adhesions on both sides. The heart and lungs were normal. The bronchial glands contained a calcareous deposit. The spleen was normal in size; on its capsule was a white spot as large as a dollar. The omentum was devoid of fat. The stomach presented indications of catarrhal inflammation. The colon was ulcerated throughout; in many places the ulcers penetrated to the peritoneum; they were largest and most numerous in the descending colon and the rectum; their edges were ragged. The other viscera were normal.—Assistant Surgeon C. F. Little, 19th Illinois volunteers.

The next twenty cases are from the case-book of the GENERAL FIELD HOSPITAL, Chattanooga, Tennessee, Assistant Surgeon Charles C. Byrne, U. S. V., in charge:

CASE 821.—Private Moses Hatcher, company C, 16th United States colored troops; age 21; admitted from the field August 11, 1864. Chronic diarrhœa. Died, August 27th. *Autopsy* next day: There were firm pleuritic adhesions on both sides, especially on the right side. The right lung was congested; the upper lobe of the left lung was congested, the lower lobe hepatized. The heart, liver and kidneys were normal. The spleen was extremely small, weighing only an ounce. The mucous membrane of the small intestine was slightly congested. [There is no record of the condition of the large intestine.]

CASE 822.—Emmanuel Tucker, contraband; age 15; admitted from the field July 18, 1864. Chronic diarrhœa. Died, August 27th. *Autopsy* the same day: The right lung was normal. The whole of the upper lobe and portions of the lower lobe of the left lung were hepatized. The heart, spleen and kidneys were normal. The liver contained a number of small abscesses about a quarter of an inch in diameter. No evidences of disease were discovered in the intestines.

CASE 823.—John Tyler, contraband. [Date of admission not recorded.] Chronic diarrhœa. Died, August 29th. *Autopsy* the same day: The thoracic viscera were normal. The liver was very much softened. The spleen was normal. Numerous ulcers of small size were found in the intestines.

CASE 824.—Private James Blair, company B, 10th Kentucky volunteers; age 28; admitted from Vining's station August 26, 1864. Enteritis. [This man appears on the register of the field hospital of the army of the Cumberland, admitted August 23d—dysentery—sent to general hospital August 24th.] Died, August 31st. *Autopsy* the same day: The lungs were normal. The heart was pale and flabby. On section the liver exuded a frothy serum. The spleen was enlarged and softened. The kidneys were generally pale but congested at points. The mucous membrane of the ileum was reddened by congestion. The mucous membrane of the colon was softened, of a dark green color, and in places had a gangrenous appearance.

CASE 825.—Private James Harmon, company D, 7th Pennsylvania cavalry; age 19; admitted from Vining's station August 27, 1864. Typhoid remittent fever. [This man appears on the register of the field hospital of the army of the Cumberland, Vining's station, Georgia, admitted August 26th—diarrhœa; no disposition.] Died, September 1st. *Autopsy* the same day: The heart, lungs, spleen and kidneys were normal. The liver was enlarged and softened. The mucous membrane of the lower part of the ileum and of the colon was softened, thickened, and studded with numerous ulcers in various stages of development.

CASE 826.—Private John W. Gray, company I, 8th Kansas volunteers; age 28; admitted from Vining's station August 27, 1864. Dysentery. [This man appears on the register of the hospital of the 3d Division, 4th Corps, admitted August 13th—diarrhœa—sent to general hospital August 24th.] Died, September 1st. *Autopsy* the same day: The posterior portion of both lungs was slightly congested. The aortic valves of the heart were thickened. The liver was softened. The spleen and kidneys were normal. The mucous membrane of the lower part of the ileum was reddened and studded with small isolated ulcers. The colon was thickened; its mucous membrane softened and of a green color.

CASE 827.—Private Isaac Shumake, company E, 27th Illinois volunteers; age 27; admitted from Vining's station August 27, 1864. Inflammation of the bowels. [This man appears on the register of the field hospital of the army of the Cumberland, Vining's station, Georgia, admitted August 25th—bloody flux—sent to general hospital August 26th.] Died, September 2d. *Autopsy* the same day: The lungs, heart, spleen and kidneys were normal. The liver weighed fifty-eight ounces and was normal in appearance. The mucous membrane of the small intestine was reddened; that of the colon, throughout its whole extent, was thickened, softened and much disorganized.

CASE 828.—William Anderson, contraband; age 25; admitted from Vining's station August 26, 1864. Diarrhœa. Died, September 2d. *Autopsy* the same day: The posterior portion of both lungs was congested. The heart was normal. The liver was softened and presented a granular appearance. The spleen and kidneys were normal. The mucous membrane of the large intestine was much thickened, softened at points, and presented many large ulcers.

CASE 829.—Willis Marshall, contraband; age 16; admitted from Chattanooga September 4, 1864. Chronic diarrhœa. Died, September 5th. *Autopsy* the same day: The right lung was stuffed with tubercles and entirely disorganized; it was strongly adherent to the thoracic parietes. The left lung contained numerous isolated tubercular deposits. The pericardium contained eight ounces of serum. In the liver and spleen there were a number of small tubercular masses. The kidneys and intestines were apparently normal. The abdominal cavity contained twenty ounces of serum.

CASE 830.—Private W. W. Greer, company D, 49th Ohio volunteers; age 31; admitted from field hospital at Marietta, Georgia, August 29, 1864. Chronic diarrhœa. Died, September 5th. *Autopsy* next day: The posterior portion of both lungs was somewhat congested. The heart, spleen and kidneys were normal. The liver was softened. The mucous membrane of the ascending and transverse colon was thickened, softened, and presented numerous ulcers, mostly old ones.

CASE 831.—Private Robert Long, company K, 16th United States colored troops; age 16; admitted from the field July 25, 1864. Chronic diarrhœa. Died, September 8th. *Autopsy* the same day: The left pleural cavity contained thirty-six ounces of fluid. There were strong pleuritic adhesions on the right side. The left lung was covered with layers of lymph and completely hepatized, the upper lobe red, the lower lobe gray; the right lung was deeply congested. The heart was pale and flabby. The liver was congested and softened. The spleen was studded with miliary tubercles. The kidneys were softened. There were a few small old ulcers in the small intestine, some of which appeared to be healed.

CASE 832.—Private Charles Riley, company B, 124th Indiana volunteers; age 21; admitted from the field hospital at Marietta, Georgia, August 29, 1864. Typhoid dysentery. [This man appears on the register of the field hospital of the army of the Ohio, Marietta, Georgia, admitted July 22d—remittent fever; no disposition.] Died, September 8th. *Autopsy* next day: Both lungs were deeply congested and contained isolated miliary tubercles. The heart was normal. The liver was very much congested. The spleen congested and softened. The kidneys were normal. The ileum was much congested and studded with small ulcers. The large intestine was almost gangrenous, and presented a number of large ulcers, many of them two inches in length.

CASE 833.—Thomas Beck, citizen; age 38; admitted from the field September 8, 1864. Chronic diarrhœa. Died, September 10th. *Autopsy* the same day: There were strong old pleuritic adhesions on both sides. On the surface of the left lung was a patch of cartilaginous hardness two inches long by an inch wide. The heart was normal. The liver presented the nutmeg appearance and was filled with masses of cartilaginous hardness, some of which were as large as a hen's egg. The spleen was enlarged, softened and congested. The kidneys were normal. The mucous membrane of the ileum and of the large intestine was congested, softened, and presented a number of old ulcers.

CASE 834.—Andrew McKee, contraband; age 20; admitted from Vining's station August 26, 1864. Typhoid fever. Died, September 13th. *Autopsy* next day: The right lung was normal; the lower lobe of the left lung was hepatized. The heart was pale and flabby. The liver and spleen were softened. The kidneys were normal. The intestinal mucous membrane was thickened and softened. Numerous ulcers were found in the small intestine, and they were still more numerous in the large.

CASE 835.—Private Thomas Ousley, company G, 16th United States colored troops; age 23; admitted from the field September 10, 1864. Enteritis. Died, September 13th. *Autopsy* the same day: The lungs were normal. The aortic valves of the heart were thickened. The heart weighed eighteen ounces. The liver was fatty and presented a mottled appearance. The spleen and kidneys were normal. The mucous membrane of the ileum was congested and softened; that of the transverse and descending colon was very much inflamed and presented a number of ulcers, some of which had nearly perforated.

CASE 836.—Private Thomas Lake, company G, 120th Indiana volunteers; age 22; admitted from the field hospital at Marietta, Georgia, August 29, 1864. Chronic diarrhœa. [This man appears on the register of the field hospital of the army of the Ohio, Marietta, Georgia, admitted August 17th—remittent fever—sent to general hospital August 28th.] Died, September 14th. *Autopsy* the same day: The lungs were slightly congested. The heart was normal. The liver was softened and congested. The spleen was normal. The mucous membrane of the intestines was thickened, softened and congested. Numerous ulcers were found in the small intestine.

CASE 837.—Private Eli Copple, company H, 80th Illinois volunteers; age 27; admitted from Vining's station August 27, 1864. Chronic diarrhœa. [This man appears on the register of the field hospital of the army of the Cumberland, Vining's station, Georgia, admitted August 24th—chronic diarrhœa; no disposition.] Died, September 16th. *Autopsy* next day: The lungs, heart, liver, spleen and kidneys were normal. The intestinal mucous membrane was thickened and softened, and there were numerous ulcers, especially in the small intestine.

CASE 838.—Private Willis Beanum, company B, 16th United States colored troops; age 27; admitted from the field September 15, 1864. Typhoid dysentery. [This man appears on the register of his regimental hospital admitted September 10th—dysentery—sent to general hospital September 15th.] Died, September 19th. *Autopsy* the same day: The lungs, heart, liver, spleen and kidneys were normal. The mucous membrane of the intestines was thickened, softened, and there were numerous ulcers, especially in the small intestine.

CASE 839.—Private John Delaney, company B, 16th United States colored troops; age 40; admitted from the field August 21, 1864. Acute dysentery. [This man appears upon the register of the hospital of the 1st Division, 14th Corps,

admitted August 12th—debility—sent to general hospital August 13th.] Died, September 22d. *Autopsy* next day: There were firm pleuritic adhesions on the right side. The lungs and heart were normal. The liver was softened. The spleen and kidneys were normal. The intestinal mucous membrane was generally congested, the congestion being most intense in the large intestine, where there were numerous minute points of ulceration.

CASE 840.—Private Randal King, company E, 16th United States colored troops; age 20; admitted from the field September 2, 1864. Pleurisy. Died, September 23d. *Autopsy* next day: The lungs were much congested, and the left lung was bound to the thoracic parietes by recent adhesions. The heart, liver and kidneys were normal. The mucous membrane of the intestines was thickened and softened, and numerous ulcers were found in both small and large intestines.

The following case is from the case-book of the UNION HOSPITAL, Memphis, Tennessee, Surgeon John D. Brumley, U. S. V., in charge:

CASE 841.—Private William C. Tallent, company M, 8th Missouri cavalry; admitted from Helena, Arkansas, October 14, 1863. Chronic diarrhœa. He was quite weak and had three or four evacuations daily. November 8th: He complained of pain in the right side of the chest, and crepitation was distinctly heard over the right lung both anteriorly and posteriorly, together with some dulness on percussion. A blister was applied. November 12th: The dyspnœa is much more severe; the pulse is weak; dulness on percussion and crepitation are observed on the left side also. A second blister was applied. Died, November 16th. *Autopsy* ten hours after death: There were pleuritic adhesions on the right side, and an effusion of two pints of serum in the right pleural sac. The lung was congested but not hepatized to any extent; its lobes were interadherent. The left lung was hepatized throughout, and there was some effusion of serum in the left pleural sac. The pericardium contained about four ounces of serum. There were large clots in the right side of the heart extending into the pulmonary vessels, a small clot in the left ventricle. The abdominal cavity contained a small quantity of serum. The mucous membrane of the lower ileum, cæcum and colon was greatly congested, dark colored, and coated with muco-purulent matter.

The next ten cases are from the case-book of the NATCHEZ HOSPITAL, Natchez, Mississippi, Assistant Surgeon A. E. Carothers, U. S. V., in charge:

CASE 842.—Private Asa Wilcox, company C, 6th Michigan artillery; age 18; admitted from Morganzia, Louisiana, per steamer Laurel Hill, June 26, 1864. Chronic diarrhœa. At the time of admission this patient was debilitated and had some diarrhœa. He stated that he had suffered from diarrhœa for several months past. He was successively treated with tincture of the chloride of iron, aromatic sulphuric acid, quinine and opium, citrate of iron and quinine, &c. Stimulants were freely used. His bowels were very troublesome at times, but seemed to be easily controlled, and his general condition appeared favorable until about the middle of July, when the diarrhœa became more persistent. During the latter part of his illness his pulse was decidedly intermittent, from which some of the ward surgeons diagnosticated organic disease of the heart; others held that it was only a functional derangement. Died, August 2d. *Autopsy* fifteen hours after death: Brain not examined. The heart was perfectly normal. The posterior portion of the lungs was greatly engorged. The stomach was normal. The spleen somewhat enlarged and softened. The liver was much darker than normal and weighed four pounds and a half. The mesenteric glands were enlarged. The intestines were diseased throughout, and extensively ulcerated in the colon and rectum. This subject had a malformation of the genital organs. The penis was perfectly formed but very small; at its base was a fold of skin representing the scrotum. There was no trace of any testicle. There was no prostate gland. The mons veneris was destitute of hair, and there was no appearance of beard. No vagina, uterus or ovaries could be found. The form of the pelvis was that of a female, but the general appearance of the body was more masculine than feminine.—Acting Assistant Surgeon James S. King.

CASE 843.—Private Solomon G. Milstead, company L, 1st Louisiana scouts; admitted September 26, 1864. Chronic diarrhœa. [This man appears upon the register of the Barracks hospital, New Orleans, admitted from his regiment July 8th—chronic diarrhœa—furloughed September 19th.] Says he has been sick four months; is anæmic and greatly debilitated; complains of no pain, and is in good spirits; urine highly colored; tongue furred; pulse 120 and weak. ℞. Mercury with chalk ten grains, Dover's powder fifteen grains, sulphate of quinia ten grains; make five powders. Take one every three hours. Two ounces of milk-punch every two hours. Died, September 27th. *Autopsy* eighteen hours after death: The lungs and heart were healthy. The abdominal cavity contained two quarts of serum. The liver was very much congested and somewhat softened. The small intestine was healthy. In the large intestine there were many ulcers, a number of which had penetrated to the peritoneal coat. The ulcers were most numerous in the rectum.—Assistant Surgeon John T. Warner.

CASE 844.—Private Charles Broadhogen, company A, 35th Wisconsin volunteers; age 30; admitted July 14, 1864. Chronic diarrhœa. Was first taken sick in May last, and has been variously treated without permanent benefit. He is now greatly emaciated, debilitated, and has from ten to fifteen discharges from the bowels daily. The stools are small and contain no blood. He complains of considerable tormina and tenesmus. He was treated successively by quinine and opium, aromatic sulphuric acid, bismuth and opium, &c., with wine and milk-punch. Died, September 28th. *Autopsy* twelve hours after death: The brain was not examined. The thoracic viscera were normal. The liver was light colored and flabby. The stomach was very much contracted. The spleen was enlarged and softened. The mesenteric glands were enlarged. The kidneys were healthy in appearance. There was diffused inflammation of the mucous membrane throughout the small intestine, with some well-marked circumscribed ulcers in the lower portion of the ileum. The large intestine was extensively ulcerated; the ulcers were mostly circumscribed and their edges were thickened; they appeared to have originated in the solitary glands. Besides these small ulcers there were many large, uneven and ragged ones. In many places all the coats of the intestines were destroyed with the exception of the peritoneum. The mucous membrane of the rectum was greatly thickened.—Acting Assistant Surgeon James S. King.

CASE 845.—Private Thomas Fauck, 26th Ohio battery; age 17; admitted November 9, 1864. Chronic diarrhœa. Was very feeble, pulse 120; complains of no pain. Died, November 12th. *Autopsy* eighteen hours after death: The thoracic viscera were healthy. The liver was pale and flabby; the gall-bladder full of bile the color and consistency of warm tar. The mesenteric glands were much enlarged. The left kidney was somewhat congested. The small intestine was healthy. The cæcum was congested; its mucous membrane softened. The mucous membrane of the rectum was softened. There were no ulcers in any part of the intestines.—Assistant Surgeon John T. Warner.

CASE 846.—Private Joseph H. Nickless, company H, 35th Wisconsin volunteers; age 25; admitted July 14, 1864. Chronic diarrhœa. When admitted he was greatly debilitated, and was having from eight to ten discharges from the bowels per day. He was quite irrational, and continued to be so for about a month. Several times he escaped from his nurses, and on one occasion they found him attempting to get to the river, as he said, to drown himself. For several weeks he said every day, at the morning visit: "Well, doctor, I guess I am pretty well, but I am playing off." About August 15th he became rational, and his condition in every way seemed to be improving. About September 20th, however, he began to decline, and died November 15th. He was treated with quinine, tonics, stimulants, &c. *Autopsy* twelve hours after death: Body very much emaciated. Brain not examined. The heart and lungs were normal. The spleen was enlarged and somewhat softened. The liver pale and flabby. The mesenteric glands were enlarged. The left kidney was congested and contracted; the right kidney was normal in size but considerably congested. The stomach was normal. There was diffuse inflammation of the mucous membrane throughout the whole extent of the small intestine, and some few circumscribed ulcers were found in the lower portion of the ileum. The large intestine was extensively ulcerated; some of the ulcers were circumscribed, others ragged. The coats of the rectum were greatly thickened.—Acting Assistant Surgeon James S. King.

CASE 847.—Private C. G. Vandyke, company D, 87th Illinois volunteers; age 21; admitted November 4, 1864. Chronic diarrhœa. When admitted he was weak, emaciated, and troubled with a cough, said to be hooping-cough; the evacuations were frequent; pulse 120; he had very little appetite. Treatment: Iron, quinine and stimulants, in connection with a cough mixture. Died, November 26th. *Autopsy:* There were a few tubercles in the apex of the left lung. The heart was flabby; its auricles very thin. The liver was very much congested and softened. The left kidney was slightly congested; the right was normal. The spleen was normal. There were a few ulcers in the lower portion of the ileum. The cæcum was very much ulcerated and thickened. The rectum was extensively ulcerated; some of the ulcers had cicatrized, in consequence of which the calibre of the gut was diminished.—Assistant Surgeon John T. Warner.

CASE 848.—Private Peter Lorton, company D, 8th New Hampshire volunteers; age 22; admitted September 25, 1864. Chronic diarrhœa. When admitted the patient was anæmic and much debilitated; pulse rapid and weak; he had very little appetite. The stools numbered from fifteen to twenty in the twenty-four hours. For the first few days he was treated with mercury and chalk, opium and quinine; afterward with quinine and iron, aromatic sulphuric acid and stimulants. He improved under treatment and was able to walk around out of doors. November 1st: The diarrhœa recurred and he complained of pains in the back. After this he gradually failed, and died November 27th. *Autopsy:* The lungs and heart were healthy. The liver was very much congested. The small intestine was healthy. The large intestine was extensively ulcerated; many of the ulcers had penetrated to the peritoneal coat.—Assistant Surgeon John T. Warner.

CASE 849.—Private Samuel W. McGeary, 26th Ohio battery; age 19; admitted November 5, 1864. Chronic diarrhœa. The patient was weak, emaciated, had very little appetite, and the evacuations were frequent. He stated that he had suffered from diarrhœa for the last three months; did not complain of any pain. Treatment: Mercury and chalk, with quinine and opium for two days; afterward quinine and iron, aromatic sulphuric acid and opium, stimulants, &c. Died, November 27th. *Autopsy* twenty hours after death: The body was greatly emaciated. The lungs, heart, liver, spleen, kidneys and small intestine presented nothing abnormal. The large intestine was ulcerated throughout, the ulcers being largest and most numerous in the rectum.—Assistant Surgeon John T. Warner.

CASE 850.—Private James Campbell, company H, 87th Illinois volunteers; age 22; admitted November 4, 1864. Diarrhœa. The patient was weak and emaciated; had very little appetite. He said that he had suffered from diarrhœa four months but is at present free from it. He is very weak and has occasional convulsions. Treatment: Quinine and iron, aromatic sulphuric acid and stimulants. At first the patient appeared to improve under treatment, but had convulsions from time to time. After November 25th he began to fail, and died December 11th. *Autopsy* fifteen hours after death: The brain was normal. The lungs, heart, liver, spleen, kidneys and small intestine were healthy. The large intestine was extensively ulcerated throughout.—Assistant Surgeon John T. Warner.

CASE 851.—Private Joseph O. Jones, company B, 8th New Hampshire volunteers; age 20; admitted from his regiment November 25, 1864. Chronic diarrhœa. When admitted the patient had about fifteen stools a day; his skin was hot, dry, and presented a bilious hue; tongue furred but moist; urine highly colored. Treatment: Quinine, iron, opium, aromatic sulphuric acid, stimulants, &c. During the first two weeks the patient appeared to improve; after that he began to complain of weakness, swelling of the feet and abdomen, pain in the bowels, and the diarrhœa grew worse. During the last few days he complained of dyspnœa and preferred the upright position. Died, January 1, 1865. *Autopsy* twenty-four hours after death: Body greatly emaciated. There were firm pleuritic adhesions on the right side and the lobes of the right lung were interadherent; miliary tubercles were scattered through both lungs. The cavity of the thorax contained two quarts of serum. The diaphragm was connected with the upper surface of the liver and the lower lobes of both lungs by a deposit of coagulable lymph. The pericardium contained three ounces of fluid. The heart was healthy. The abdominal cavity contained two quarts of serum. There were extensive peritoneal adhesions. The spleen was hard and much enlarged, weighing two pounds. The liver was congested. The kidneys were small and congested. The pancreas large and firm. A firm compact morbid growth of about the color of the

pancreas, and thirteen inches in length, was found in the mesocolon of the transverse colon close to the bowel and parallel to it. It was about two inches in width and an inch thick opposite the transverse fissure of the liver, from which it gradually tapered to the under surface of the spleen, where it was adherent. From this mass a fibrous band was thrown out which encircled the colon and had greatly lessened its calibre. The small intestine was healthy. In the cæcum and colon there were a few circumscribed ulcers. The rectum was extensively ulcerated. The mesenteric glands were enlarged.

The histories of the next eight cases were forwarded, with the specimens and the accompanying letter, from HOSPITAL No. 3, Vicksburg, Mississippi. The series includes one case, that of Roberts, No. 855, in which the patient died in regimental hospital:

HOSPITAL NO. 3, VICKSBURG, MISSISSIPPI,
December 24, 1863.

TO THE SURGEON GENERAL OF THE ARMY.

SIR: It is proper for me, in justice to myself, to state that I am not responsible in any instance for the professional treatment of the cases herein reported. Not a single case came under my care until after the disease had become chronic, the patient greatly emaciated and enfeebled—until, I might almost add, the disease had ceased to be amenable to treatment. At the same time great pains have been taken to collect a complete history of the cases previous to coming under my observation, and this has been derived from the combined statements of the patient, his nurse and physician. I have personally made all the post mortem examinations and described all the pathological appearances with as much accuracy as was attainable under the circumstances. I have hunted up the cases in different hospitals, made the autopsies, often under very adverse circumstances, and have never been able to avail myself of the aid of the microscope; consequently, when I remark on the condition of the liver, my observations are superficial and do not involve an examination of the cell-structure; so too of the kidney and the intestine. The treatment which I have adopted for what is commonly denominated chronic diarrhœa, but which in most instances is chronic dysentery, is derived from experience and the study of the pathology of the disease. After first unloading the bowels and their distended vessels and glands by an appropriate cathartic—a saline if there is acute inflammation, blue pill or mercury with chalk if a cholagogue is indicated—the tenesmus and pain are allayed by an opiate enema. The patient is then restricted to boiled milk, poached eggs, fowl, farinaceous articles of diet, and pure wine as occasion requires. In chronic cases stimulating enemata, such as turpentine, seem rational. During the summer and fall I have treated about one hundred and fifty cases on this plan, and all those whom I have been able to subject to the above treatment, upon the first accession of the disease, have invariably, without a single exception, recovered, and many even after the disease had become chronic. The too common treatment of the disease by astringents and mercurialization should be execrated.

Very respectfully, your obedient servant,

GEORGE F. FRENCH,
Surgeon U. S. V.

CASE 852.—Private Helvin Ellisson, company C, 5th Minnesota volunteers; admitted October 10, 1863. Dysentery. This patient was taken sick in June with intermittent fever and diarrhœa, which some time in July ran into dysentery and brought him very low; he rallied, however, and was able to walk about for a week or two, but suffered a relapse and was brought to this hospital. At the time of admission there was considerable œdema of the lower extremities, copious bloody stools attended with moderate febrile action, and dry tongue. Subsequently the stools became dark and slimy; they never presented the white mucous or gelatinous appearance so often met with. They varied in number from five to twelve daily. The appetite, which was at first good, soon failed. He continued to lose flesh and strength and died October 31st. Treatment: Opiate and turpentine injections, chalk mixture, Tarragona wine and porter, boiled milk and farinaceous diet. *Autopsy* ten hours after death: The heart, lungs, liver, spleen and kidneys were normal. The mesenteric glands were enlarged. The entire tract of the large intestine was eroded with ulcers, and the mucous membrane was thickened, in some places to two or three lines thick; the hypertrophy was greatest in the cæcum. The ulcers were not, as in many cases, circumscribed and oval, but the whole tract had a worm-eaten aspect and the ulcers intersected each other in every direction, most of them running transversely; the majority were superficial; a few, however, almost penetrated the muscular coat. [Nos. 138 to 143, Medical Section, Army Medical Museum, are from this case. The specimens are successive portions of the thickened colon, exhibiting numerous irregular ulcers, most of which are superficial and appear to have resulted from the separation of diphtheritic sloughs; scattered patches of pseudomembrane adhere to the surface of the mucous membrane between the ulcers. Nos. 138 and 139 are from the ascending, Nos. 140 and 141 from the transverse, and Nos. 142 and 143 from the descending, colon.]

CASE 853.—Private Charles C. Tufts, company C, 114th Illinois volunteers; age 32; nervo-bilious temperament; occupation peddler; admitted October 12, 1863. Chronic dysentery. This man had a tendency to diarrhœa for the last seven years. Some time ago he had an attack of hæmoptysis. Had lost a brother by phthisis. Was attacked by diarrhœa in March; it continued intermittently until September 20th, when he had an attack of dysentery, passing much blood; stools from eight to fifty daily. He was delirious and had typhoid symptoms, which, however, soon passed off. At first there was much tenesmus and tormina, which injections relieved. There was considerable tenderness of the abdomen. After the first few days the stools became small, jelly-like and white, and after the first two weeks they diminished to from five to three a day. Throughout there was anorexia with great thirst, and moderate œdema of the lower extremities. November 1st: He was extremely emaciated; respiration 18 per minute; pulse 120, weak and fluctuating; tongue smooth and rather dry; slight sordes on the teeth for the last fortnight. Treatment: Injections of opium and acetate of lead; stimulants given freely from the beginning. Diet: Boiled milk, rice, farina and beef-essence. Died. November 3d. *Autopsy* twenty-four hours after death: Isolated calcified tubercles were found in the middle of the upper lobe of each lung and pleuritic adhesions at both apices. Calcified tubercles were also found in the mesenteric glands. The stomach and duodenum were normal. Dark mahogany colored patches of inflammation

were observed here and there along the whole tract of the ileum, becoming more diffuse and intense toward the cæcum, where there was a greenish discoloration and softening of the mucous membrane; the inflammation became diffuse in the ileum about two feet from the cæcum, and the mucous membrane below that point was intersected transversely by ragged elevated granulations and granular ulcerations, which increased in size and number as they approached the cæcum. One or two of Peyer's glands were studded with minute ulcers. The cæcum and ascending colon were overspread with minute points of ulceration of a dark-red color, which seems to have slightly invaded the muscular coat. The greatest amount of disease was observed in the transverse colon, where the ulcers were quite numerous, many extending almost through the muscular coat and varying in size from that of a pin-head to that of a pea; the ascending and descending colon, however, were thickened more than the transverse. The descending colon and rectum exhibited numerous elevated mahogany colored patches of inflammation, and the rectum was roughened with superficial granular ulcerations and shreddy exudations of lymph. [No. 144, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the descending colon the mucous membrane of which presents a number of follicular ulcers; some little pseudomembrane adheres to the mucous surface between the ulcers.]

CASE 854.—Private Christian Able, company F, 30th Missouri volunteers; age 35; admitted November 6, 1863. Chronic diarrhœa. September 10th, he was attacked by intermittent fever, which passed off in about a week, and was succeeded by an attack of dysentery attended with bloody stools at first numbering twenty-five or thirty daily, but diminishing in a few days to nine or ten. Latterly the stools have been small, dark colored or green, usually gelatinous, but at times frothy. Diarrhœa and dysentery have alternated. Several times the patient has been better, but shortly suffered a relapse. He has not at any time suffered much from tormina or flatulence, and his appetite has always been good until recently. His tongue is red, moist and fissured. The treatment has consisted in the use of astringents and opium, with an occasional pill of blue mass. Has never had injections. The diet has been limited to farinaceous articles, and port-wine was given as a stimulant. Died, November 10th. *Autopsy* six hours after death: Spots of purpura hæmorrhagica were noticed on the forehead, chest and abdomen; (these first appeared a day or two before death.) A few isolated calcareous tubercles and two or three cicatrices were found at the apex of the left lung; otherwise the lungs were perfectly healthy. The heart exhibited a few white fibrous patches the size of a dime on its anterior surface. The gall-bladder was rather large and full of dark-red bile; the inner coat of the gall-bladder was thickened and of a dark-orange color; its external surface was not tinged with bile as usual. The cystic duct was completely occluded for half an inch before its junction with the hepatic. The liver weighed two pounds and a quarter; the upper surface of its right lobe was slightly roughened with white fibrous deposits; the capsule of the liver generally was thickened, and presented here and there elevated white patches and striæ; it separated easily from the parenchyma of the organ, which was friable, of a deep-red color, and presented the hob-nail appearance in the upper part of the right lobe and a small portion of the posterior surface of the left lobe. The spleen was normal. The mesenteric glands were enlarged, many to the size of a horse-chestnut, and filled with a cheesy substance. At the pyloric end of the stomach the mucous membrane was deep red and soft; the same condition extended three or four inches into the duodenum, where the color was deeper and spotted with dark-red points. The duodenal glands were slightly enlarged and prominent. The jejunum was of a livid red, its valvulæ conniventes tinged yellow. At the beginning of the ileum there was a thickened and broken-down Peyer's patch four inches and a half long; lower down diseased Peyer's patches were numerous; in the lower half of the ileum there were also deep-red points more or less thickly clustered together. The disease of Peyer's patches is not so extensive near the cæcum as is usual in typhoid fever. The mucous membrane of the cæcum was of a dark-red color. A few small superficial ulcers about the size of pin-heads were scattered throughout the descending colon, and half through the transverse colon, here and there, were larger ulcers and a few dark colored corrugated elevations. The solitary glands of the colon appeared as numerous white points the size of pin-heads, delicately punctated in the center. The mucous membrane of the rectum was thickened and of a deep livid red with mahogany colored spots and striæ; it presented a few ulcers varying from the size of the head of a pin to that of a pea; these ulcers were most numerous in the upper part of the rectum. The contents of the small intestine were yellowish-green and frothy. The rectum was full of dark-green fæcal matter.

CASE 855.—Private Lewis Roberts, company B, 1st Mississippi volunteers; taken sick October 27, 1863, with watery diarrhœa, which, November 1st, ran into dysentery, with small bloody and mucous stools numbering at first forty a day, latterly only eight or nine. There was great tenesmus throughout, but not much tormina or flatulence. The pulse was about 100, small and feeble; the appetite good. The tongue was at first covered with a white dry fur, which passed off, and he seemed rapidly recovering, when he indulged in some improper food and suffered a relapse, with copious watery stools, and died November 12th. Treatment: In the commencement of the attack he took a moderate cathartic, which was followed by twelve grains of calomel in divided doses, combined with opium and ipecacuanha; he also had turpentine emulsion, but never any injections. Diet: Potato soup, rice and dried fruit. *Autopsy* five hours after death: The spleen was very small, about two-thirds the size of an ordinary kidney. The stomach was normal. At the beginning of the jejunum were a number of mahogany colored patches involving the entire circumference of the intestine; these patches were more extensive lower down and more intensely red in the ileum, which was very vascular but not softened; here and there the surface of the inflamed tracts presented a granular appearance. Six inches above the cæcum one of Peyer's patches was elevated, deep red and granular; a little higher up another patch, larger than the former, was softened and broken down. There was deep red inflammation of the cæcum and rectum, intersected by streaks of a deeper red color; very little ulceration was observed, and that was confined to the rectum, where there were a few small ulcers commencing in the solitary glands, which were enlarged to four or five lines in diameter, very red, elevated and broken down in the center; the lower part of the rectum was thickened and overspread with deep-red granulations.—Hospital of the 1st Mississippi volunteers, Vicksburg, Mississippi.

CASE 856.—Private James H. Rynders, company H, 4th Iowa cavalry; admitted October 10, 1863. Had diarrhœa for nine months before death. It commenced with an attack of dysentery which lasted five weeks, and began with frequent bloody stools, which in a day or two greatly diminished in number, becoming mucous and gelatinous. At the end of five weeks the

disease ran into diarrhœa, since which time diarrhœa and dysentery have alternated. November 16th: Pulse frequent and feeble; tongue dry, red and covered with a ragged white and yellowish fur. Nothing is known of his treatment up to the date of admission, since which time he has taken opium, subnitrate of bismuth in large doses, and blue mass at intervals. Porter and brandy were given freely. His diet has been almost exclusively farinaceous. Died, November 17th. *Autopsy* ten hours after death: There were a few calcareous tubercles and cicatrices in the apex of each lung; the lungs were otherwise healthy. The spleen was the size of a small kidney. There was deep vascular congestion of the duodenum and jejunum. The intestines were full of a yellowish-green fluid. At the beginning of the ileum the inflammation deepened, became diffuse, and had gone on to softening; the inflammation was not continuous, but interrupted here and there by a healthy tract a few inches long. At the lower end of the ileum a few of Peyer's patches were slightly prominent. The large intestine, with the exception of the cæcum, was thickened, cutting like cartilage. The cæcum was of a deep-red color, and its mucous coat was softened. The rest of the large intestine presented a whitish base, mottled and discolored with livid green and purple spots; the whole colon was thickly studded with small ulcers, with here and there a large one; the ulcers were deep and involved the submucous coat, to which the thickening was limited. There were also patches of adherent pseudomembrane, especially in the lower part of the colon. Some of the ulcers seemed to be healing. [Nos. 119 to 123, Medical Section, Army Medical Museum, are from this case. The specimens are successive portions of the thickened colon, presenting numerous follicular ulcers. Nos. 119 and 120 are from the ascending, No. 121 from the transverse, Nos. 122 and 123 from the descending, colon.]

CASE 857.—Private William T. Beam, company E, 5th Illinois cavalry; age 21; admitted October 10, 1863. Diarrhœa. Has been in the army two years; sick for eight months. At first he had a brief attack of intermittent fever, which was succeeded by an attack of dysentery of three or four days' duration; diarrhœa supervened with watery stools, followed in a week by another attack of dysentery; subsequently the two diseases have alternated. Upon the first accession of dysentery the stools were very bloody and occurred every hour, but soon diminished, as at present, to five or ten a day. November 9th: The stools are small, shreddy, gelatinous and sometimes white; the tenesmus is very slight. Up to the first of November his appetite was capricious; since then it has entirely failed. November 15th: The tongue is moist, its surface shreddy; the pulse feeble and rapid. Died, November 19th. Treatment: Opium pills and occasionally turpentine emulsion. Since admission to this hospital he has taken chalk mixture and blue mass; as a stimulant, Tarragona wine; never had enemata until November 9th. Diet principally farinaceous. According to his statement he ate the ordinary ration up to September 20th. *Autopsy* six hours after death: The lungs were healthy but firmly bound to the thoracic parietes on all sides by old pleuritic adhesions. The mesenteric glands were dark and slightly enlarged. The spleen was rather large. The liver of a deep-red color. In the middle of the jejunum there was a tract six inches long of a livid-red color and softened; a similar tract was observed a foot farther on. The entire ileum was of a deep livid red and softened, except just above the cæcum, where the bowel appeared to be quite healthy. The solitary glands in the lower portion of the ileum were enlarged almost to the size of small shot. Peyer's glands were healthy. The cæcum was dark red and softened; the transverse colon comparatively healthy. From the beginning of the descending colon to the anus the mucous membrane was completely eroded, except here and there a few isolated elevated spots and patches; but few of the ulcers involved the muscular coat. The rectum was of a deep-red color and softened; the ulcers situated here were filled with still deeper red, adherent, grumous clots. [Nos. 145 and 146, Medical Section, Army Medical Museum, are from this case. No. 145 is from the lower portion of the ileum, and exhibits pin-head enlargement of the solitary follicles with hypertrophy of the villi. No. 146 is from the transverse colon, and presents numerous irregular ulcers such as result from the separation of diphtheritic sloughs.]

CASE 858.—Private William H. Grommon, 2d Iowa battery; age 33; admitted October 10, 1863. Chronic dysentery. This man was never hardy, but has been healthier since he entered the army. Has been subject to ague for years; since entering the service has had diarrhœa occasionally; uses alcohol to excess. Was taken sick July 5th, at Big Black, with a mild attack of dysentery, but continued to walk about until the date of admission. In a short time he improved and went into convalescent camp, but had a relapse of dysentery about the first of November. The stools were at first copious and bloody, but soon became small and gelatinous, continuing so until death, November 20th. He did not suffer from flatulence or tormina, and his appetite was moderately good throughout. Treatment: Opium, tannic acid and subnitrate of bismuth were administered alternately, with an occasional dose of blue mass; never had any injections. Tarragona and port-wine were given as stimulants. Diet: Rice, farina, vegetable soup and meat. *Autopsy* twelve hours after death: The lower lobes of both lungs were hepatized partly red partly gray. The pericardium contained much serum and was roughened with soft yellow lymph. The spleen was abnormally soft, and attached to the diaphragm by its upper end with a strong fibrous adhesion, and on its free surface slightly roughened with a few ragged white fibrous shreds. In the center of its convex free surface there was a glossy white cartilaginous patch about an inch square, which in its central portion was thickest, and gradually became thinner until it shaded off into the investing membrane, of which it seemed to be merely a thickening. The kidneys were normal. The stomach was healthy. In the jejunum there were a few small tracts of moderately diffused inflammation attended by a limited degree of softening. Some similar patches of inflammation were observed in the ileum, but Peyer's patches were not involved. Inflammation of the same character was also noticed in the cæcum and ascending colon, but there was no ulceration. Superficial ulcers were sparsely scattered in the transverse colon, and increased in number and size toward the anus. The mucous membrane of the colon was livid and dark. The ulcers, which were limited to the mucous coat, had ragged, elevated, everted edges, and contained a dirty yellowish-white flocculent lymph, which, when with difficulty removed, disclosed a very deep red, smooth and glossy base. In the lower half of the colon, and more especially in the rectum, the mucous and muscular coats were greatly hypertrophied. [Nos. 129 to 131, Medical Section, Army Medical Museum, are from this case. The specimens are portions of the thickened colon, presenting a number of follicular ulcers, which, in No. 131, have for the most part extended into irregular erosions which occupy the greater portion of the mucous membrane. Pseudomembranous lymph adheres to the surfaces of the ulcers.]

CASE 859.—Corporal Daniel B. Davidson, 2d Iowa battery; age 22; admitted October 10, 1863. Chronic dysentery. July 4th: Had an attack of dysentery and passed a moderate amount of blood, suffering considerably from tormina and tenesmus; small white mucous stools succeeded, numbering about fourteen daily for awhile, but subsequently reduced in number to five or six. The last portions of these mucous stools were streaked with blood and were very offensive. In about two weeks from the commencement of the attack the stools began to partake more of the nature of diarrhœa, which has not since ceased, and at times is complicated with mild dysenteric symptoms. For two weeks in August the patient had intermittent fever, the diarrhœa continuing. October 10th: When admitted he was in a very low typhoid condition. Since admission the stools have been thin, watery and very fetid. Died, November 21st. *Autopsy* ten hours after death: There were old pleuritic adhesions on the left side. The heart was normal. The spleen was pale. There was a congenital anomaly of the liver, the left lobe being larger than the right. The kidneys were normal. There was marked vascularity throughout the small intestine, much more in some tracts than others, and greater in the ileum than in the jejunum, but there was no softening of the mucous membrane; Peyer's glands were conspicuous. The entire tract of the small intestine was studded with elevated solitary glands about the size of pin-heads, but larger in the duodenum than elsewhere; they were of the same color as the mucous coat, and delicately punctated in their centers. In the colon these glands were not elevated above the surface; their circumference was of a darker color and their centers more distinctly punctated. The transverse and descending colon and the rectum were reddened and spotted with deep mahogany colored stains, with here and there livid and dark-green tracts. There were a few follicular ulcers in the colon, and several large ragged ulcers extending transversely across the lower portion of the rectum, where also some ash-colored granulations appeared on the surface of the mucous membrane. [Nos. 126 to 128, Medical Section, Army Medical Museum, are from this case. No. 126 is a portion of the jejunum, No. 127 of the upper portion of the ileum; in both there is moderate hypertrophy of the villi, and the solitary follicles, enlarged to the size of pin-heads, project as tumors above the surface of the mucous membrane. No. 128 is a portion of the ascending colon near the cæcum, which presents a few small follicular ulcers.]

The note of the following case was forwarded to the Museum, with the specimen, from UNIVERSITY HOSPITAL, New Orleans, Louisiana, Assistant Surgeon Phineas S. Conner, U. S. A., in charge:

CASE 860.—Private George D. Knowlton, company I, 36th Massachusetts volunteers; age 26; admitted March 30, 1863. Chronic diarrhœa of many months' duration. Died, April 14th. *Autopsy:* Numerous ulcers were found in the lower three feet of the ileum and upper part of the colon as well as in the appendix. [No. 83, Medical Section, Army Medical Museum, is from this case. The specimen is the appendix vermiformis laid open and presenting a number of follicular ulcers on its mucous surface.]

The notes of the following case were forwarded to the Museum, with the specimen, from DRUM BARRACKS, California, by Surgeon S. S. Todd, 4th California volunteers:

CASE 861.—Private William A. Monier, company B, 4th California volunteers; age 35; was attacked with diarrhœa while marching with his company from Fort Mojave, on the Colorado river, Arizona territory, to Drum Barracks, California, December 11, 1863. The attack began about ten days after leaving Fort Mojave, was mild, and he continued to march for two days, when he was ordered into a wagon. The train was unprovided with medicines or a medical officer, and the first attendance he received was after reaching the city of Los Angelos on the 24th, eight days after the beginning of the attack. The diarrhœa had passed into dysentery, and bloody mucus was contained in the stools on the third day of the attack; on the seventh day retention of urine took place. On reaching Los Angelos he was visited by Acting Assistant Surgeon R. F. Hayes, who found him suffering from retention of urine, with frequent discharges of bloody mucus from the bowels, and painful tenesmus accompanied with prolapsus of the rectum. The urine was drawn off with the catheter, the prolapsus reduced, and the patient treated with opiates, mercurials and soothing enemata until the 28th of December, when he was brought to Drum Barracks, where he was first seen by the reporter. At this time he was still suffering with dysentery and retention of urine, but there was no febrile excitement, nor was there any tenderness of the iliac region on pressure. The pulse was not quite 90. Pills of opium, ipecacuanha and calomel were now prescribed, with a laudanum enema after each evacuation. (He had at this time a stool every two or three hours.) On the 1st of January, a tubular diphtheritic cast of the bowel, fourteen inches in length, was found in the patient's bed. He now slowly improved, but it was necessary to continue the use of the catheter until January 18th, when he was able to pass water without the instrument. By the 3d of February he was able to leave his bed and walk about the ward without assistance. The improvement, however, was only temporary; the flux soon recurred in the form of an obstinate diarrhœa, and he died April 25th. [No. 382, Medical Section, Army Medical Museum, is from this case. The specimen is the diphtheritic cast above described, which proved on microscopical examination to be composed of pseudo-membranous lymph in which no traces of the structure of the mucous membrane could be detected.]

The next eight cases were observed at the FREEDMAN'S HOSPITAL, Washington, D. C., during 1865, 1866, and 1867.* In none of them were the patients soldiers. Five are of interest as examples of tubercular ulceration of the intestines. Besides the specimens from these cases, several other examples of tubercular ulceration of the intestines are preserved

* During this period two of the hospital stewards on duty in the Museum, D. S. Lamb and S. S. Bond, were frequently sent to the Freedman's Hospital for the purpose of making autopsies. A considerable number of specimens illustrative of the diseases of the freedmen were thus obtained.

at the Museum, which were obtained from autopsies of colored women who died at the same hospital during the period mentioned. These are Nos. 612, 677, 678, 679, 692, 725, 776, and 798, Medical Section. Detailed accounts of these autopsies will be found in the Catalogue of the Medical Section.* In all of them extensive tubercular deposits were found in the lungs and other organs. Most of the specimens are portions of the ileum with tubercular ulcers of the mucous membrane and miliary tubercles on the peritoneal surface opposite:

CASE 862.—Stephen Green, a dark mulatto; age 31; admitted September 5, 1865. When admitted he had dulness on percussion under both clavicles, pain on pressure under the clavicles and over the stomach, and cough causing pain in the præcordial region. He was extremely emaciated and had night-sweats; his bowels were constipated; his appetite good up to three hours before death. Died, December 17th, at 10 A. M. *Autopsy* sixteen hours after death: Height five feet three inches; weight about 120 pounds; some emaciation; rigor mortis well marked. The brain weighed forty-six ounces and a half; the pia mater was congested; there was an ounce of serum in the subarachnoid space, a drachm in each lateral ventricle; the substance of the brain was soft. The cerebellum was congested, its substance very soft; the posterior fossæ of the cranium contained two ounces of serum. The upper portion of the left lung was slightly adherent to the pleura costalis; there were a number of small vomicæ throughout its upper lobe; the lung was filled with gray tubercles; it weighed twelve ounces; the upper portion of the right lung was firmly adherent, the lower portion adherent by numerous fibrinous bands; the upper lobe contained numerous vomicæ, some as large as a bulled walnut, and was filled with tubercles; the lower lobe was congested and contained many tubercles; it weighed nineteen ounces. The pericardium contained no fluid. The heart was very dark colored and congested; there was a large firm white clot in the right ventricle extending into the pulmonary artery; a similar one in the right auricle; also a small one in the left ventricle, which extended into the aorta; the valves were normal; the heart weighed eight ounces. The liver was small and congested; it presented a mottled appearance externally and was of a dark reddish brown internally. The spleen was small and shrivelled; it was of a light-blue color and weighed three ounces and a half. The right kidney was small; its cortical substance congested and fatty; it weighed three ounces; the left kidney weighed three ounces and a half and was in the same condition as the right. The mucous membrane of the stomach was thickened and slightly congested; that of the duodenum much thickened and unusually congested; that of the jejunum thickened, congested, and a few of the solitary glands ulcerated. In the upper portion of the ileum Peyer's patches were slightly ulcerated and the gut considerably congested; in the middle portion a number of the glands were ulcerated; some of the ulcers were scooped out, with rough irregular edges, others had thickened raised edges; some of the patches contained deposits of tubercles [?]; in the lower portion Peyer's patches were extensively ulcerated; near the ileo-cæcal valve the ileum was very much congested. The cæcum was filled with hard fæces, was much congested, and presented ulcers over nearly half its surface. The ascending colon was much distended at the hepatic flexure with a collection of hard fæces; the transverse colon was very large, and distended with gas to fully three inches in diameter; the descending colon was sacculated and contained a collection of hard lumpy fæces. The sigmoid flexure was distended with gas. The rectum contained lumps of hard fæces. The colon presented numerous points of ulceration throughout its whole extent, particularly at the points containing fæces, which had the appearance of having been confined for some time at these places. The bladder was small, its walls slightly thickened; it contained a small quantity of pus like fluid.—Hospital Steward Samuel S. Bond. [No. 674, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the ileum taken from near the ileo-cæcal valve, showing a Peyer's patch, which is moderately thickened and presents a considerable number of small ulcers.]

CASE 863.—Frank Williams; dark mulatto; age 14; admitted May 24, 1865, suffering from scrofulous ophthalmia. Symptoms of phthisis pulmonalis were first noticed about the middle of October. There was marked dulness on percussion on the left side beneath the clavicle and over the second, third and fourth ribs; expectoration very copious during the last four weeks; hæmorrhage occurred very profusely for the first time, February 4, 1866, about 5 P. M. The boy died in three or four minutes. Treatment: Cod-liver oil, whiskey, nourishing diet, milk-punch, etc. His diarrhœa was not troublesome except during the two or three days preceding death. *Autopsy* twenty-two hours after death: Body well formed; height four feet nine inches; some emaciation; rigor mortis well marked; weight about 80 pounds. The brain weighed forty-four ounces; its membranes were congested, its substance firm; there were two ounces of fluid in the posterior fossæ of the cranium. The right lung was firmly adherent to the pleura costalis, filled with crude tubercles and vomicæ, and weighed fifteen ounces; there were three ounces of fluid in the right pleural cavity; the left lung was firmly adherent at all points, its lobes interadherent; it weighed twenty-three ounces; in the upper lobe of the left lung was a large vomica the size of a goose egg, which was filled with coagulated blood; tubercles and smaller vomicæ were scattered throughout the lungs. The left pleural cavity contained an ounce of fluid. The bronchial glands were very much enlarged. The heart was small, slightly fatty, and weighed five ounces; all its valves were thickened. The pericardium contained eight ounces of fluid. The liver weighed forty-one ounces, was adherent at all points, its anterior surface coated with lymph; on section it was found to be very fatty and congested, presenting the nutmeg appearance, and contained some tubercles. The spleen weighed four ounces, was adherent at all points, and filled with tubercles. The pancreas and kidneys were normal; the latter weighed three ounces each. The mesenteric glands were very much enlarged. The stomach was normal. Two large tubercular ulcers were found in the ileum near the ileo-cæcal valve. The rest of the small intestine was normal. In the cæcum a few of the solitary follicles were enlarged. A large tubercular ulcer, involving the mucous and muscular coats, was found in the ascending colon; on the peritoneal surface opposite this ulcer

* Washington, Government Printing Office, 1867.

there were numerous minute tubercles; a similar but much larger ulcer was found in the transverse colon; with these exceptions the large intestine was normal. The abdominal cavity was filled with serum, and the intestines were slightly adherent to the abdominal peritoneum. The large intestine was three feet and a half long, the small intestine nineteen feet. The urino-genital organs appeared healthy.—Hospital Steward Samuel S. Bond. [Nos. 720 and 721, Medical Section, Army Medical Museum, are from this case. No. 720 is a portion of the transverse colon, showing a number of minute follicular ulcers; near the middle of the piece is a large tubercular ulcer running obliquely to the axis of the gut. On the peritoneal surface opposite the ulcer are a considerable number of minute tubercles; a few others are scattered on other portions of the peritoneal surface. No. 721 is a portion of the omentum containing a large number of minute tubercles.]

CASE 864.—John Thomas; dark mulatto; age 13; admitted January 22, 1866, with feet and legs frost-bitten to the knees. Stimulating liniments were applied and stimulants given internally; generous diet. January 28th: Mortification of the left leg has taken place, with line of demarcation half way to the knee. Amputation was performed, by Acting Assistant Surgeon A. R. Abbott, at the upper third of the left leg. The toes of the right foot sloughed off; the bones were removed by nippers. January 29th: Symptoms of jaundice. To take dilute nitric acid and fluid extract of gentian. February 23d: Symptoms of tuberculosis. Cough-mixture, milk-punch and extra diet. Died, March 28th. *Autopsy* ten hours after death: Height four feet six inches; weight about fifty pounds; much emaciation; rigor mortis well marked. The left leg exhibited a stump a few inches below the knee; all except the first phalanges of the toes of the right foot are wanting. The head was not examined. The right lung weighed twenty-four ounces; its lower lobe was firmly adherent to the pleura costalis and the diaphragm; all the lobes were firmly interadherent and contained large masses of crude tubercles; in the anterior portion of the lower lobe there was a mass of tubercle containing a cavity the size of a walnut; the posterior portion was hepatized; the left lung weighed ten ounces, was slightly adherent to the pleura costalis, and contained many tubercles; there was no fluid in the pleural cavities. The pleura costalis was dotted with numerous deposits of tubercles. The bronchial glands were much enlarged and filled with tubercles. The pericardium contained four ounces of fluid. The heart was fatty and weighed five ounces; all its cavities contained white fibrinous clots; the endocardium was thickened; there was a large deposit of adipose tissue on the surface of the organ. The liver was firmly adherent to the diaphragm, coated with lymph superiorly, and filled with tubercles; it weighed thirty-three ounces. The spleen was large and weighed seven ounces and a half; it was firmly adherent to the diaphragm and almost a mass of tubercles. The pancreas weighed two ounces and a half; it was apparently normal. The stomach was contracted, its mucous membrane thickened. There were tubercular ulcers throughout the small intestine, particularly in the lower portion of the ileum, where Peyer's patches were ulcerated through to the peritoneal coat. The cæcum and upper portion of the large intestine exhibited healed ulcers; the rectum contained a number of large ulcers which were covered with pseudomembrane. The kidneys were congested and weighed three ounces and a half each. The bladder and genital organs were normal.—Hospital Steward Samuel S. Bond. [Nos. 771 to 773, Medical Section, Army Medical Museum, are from this case. No. 771 is a portion of the small intestine from just above the ileo-cæcal valve, showing tubercular ulceration of the last Peyer's patch and of several of the solitary follicles. There are a few small tubercles on the peritoneal surface corresponding to the ulcers. No. 772 is a portion of the rectum, with patches of superficial ulceration coated with thick pseudomembrane. No. 773 is the right lung of the same patient, infiltrated with large cheesy masses of yellow tubercles.]

CASE 835.—Robert Franklin; mulatto; age 33; admitted February 3, 1866. Consumption. Nothing of special interest was developed in the progress of the case. Died, March 29th. *Autopsy* twenty hours after death: Height six feet; approximate weight 160 pounds; a stout muscular man; rigor mortis well marked; no emaciation; abrasions on the lower extremities. The brain weighed forty-eight ounces; its membranes were slightly congested; there were four drachms of fluid in each lateral ventricle; the choroid plexus was congested, the pineal gland enlarged and contained calcareous deposits; the substance of the brain was slightly softened; the cerebellum was also somewhat softened; in the posterior fossæ of the cranium there was half an ounce of fluid. The right lung was coated with croupous lymph, congested, and contained much crude tubercle and a few vomicæ; its lobes were firmly interadherent; it weighed twenty ounces; there were six ounces of fluid in the right pleural cavity; the left lung was slightly adherent to the diaphragm, its lobes interadherent; its lower lobe was hepatized, its upper lobe congested; the lung contained a small amount of tubercles; it weighed thirty-five ounces; the left pleural cavity contained four ounces of fluid. The pericardial sac contained five ounces of serum. The heart was large and covered with an excessive amount of adipose tissue; its valves were very dark and congested; the organ was very fatty and weighed thirteen ounces; the aorta atheromatous. The liver weighed seventy-six ounces; its upper surface was normal in color, its lower surface dark-green and contained a few miliary tubercles; the gall-bladder was empty. The spleen contained a small quantity of tubercles, was very firm, and weighed fourteen ounces. The pancreas was of a greenish color and very soft; it weighed five ounces. The kidneys were very fatty and weighed eight ounces each. The mucous membrane of the stomach was thickened. The duodenum and jejunum were normal. The ileum presented a number of large scooped-out tubercular ulcers; on the peritoneal surface opposite the ulcers were deposits of tubercle. The cæcum and vermiform appendix exhibited a few tubercular ulcers. In the ascending and transverse colon there were a few scooped-out ulcers with irregular edges, which penetrated to the peritoneal coat. The large intestine was eight feet long, the small intestine thirty-three feet. The abdominal parietes were of a dark-greenish color.—Hospital Steward Samuel S. Bond. [No. 774, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the ileum with several large ulcers; the villi around the edges of the ulcers are hypertrophied. There are tubercular deposits on the peritoneal surface corresponding with the ulcers.]

CASE 866.—James Evans; light mulatto; age 20; admitted May 3, 1866, between 10 and 11 A. M. No diagnosis. Died, May 4th, at 8 A. M. *Autopsy* twenty-eight hours after death: A well-formed man; height six feet; weight 150 pounds; rigor mortis partial; some ecchymoses; body covered with copper-colored spots. The brain weighed forty-eight ounces, its membranes were much congested; there was a drachm of fluid in each lateral ventricle; the membranous lining of the ventricles and the choroid plexus were congested. There were a few spicula of bone in the walls of the longitudinal sinus; the membranes of

the cerebellum were very much congested; the entire substance of the brain was soft, and there was much effusion beneath the arachnoid. In the posterior fossæ of the cranium there were two ounces of serum. The right lung weighed thirty-six ounces and was adherent at all points, its lobes interadherent; the upper and middle lobes contained vomicæ and were filled with crude tubercles; the lower lobe was congested and also contained tubercles; the left lung weighed twenty-six ounces; there were numerous vomicæ and tubercular deposits throughout; it was connected by firm adhesions to the pleura costalis. Each pleural cavity contained four ounces of fluid. The heart weighed twelve ounces; there were adipose deposits on its surface and clots in all its cavities. The liver weighed seventy-nine ounces and was very fatty; the gall-bladder contained half an ounce of bile. The spleen was lobulated, pale slate color externally, reddish internally; it weighed nine ounces. The pancreas weighed four ounces and was apparently normal. The kidneys were fatty; they weighed five ounces each. The stomach and duodenum were congested. The remainder of the small intestine and all of the large intestine exhibited extensive tubercular ulceration, with deposits of tubercle on the peritoneal surface opposite the ulcers. Length of large intestine four feet and a half, small intestine twenty feet.—Hospital Steward D. S. Lamb. [Nos. 808 and 809, Medical Section, Army Medical Museum, are from this case. No. 808 is a portion of the ileum, showing tubercular ulceration of two large Peyer's patches and several solitary follicles; the peritoneal surface opposite the ulcers presents a number of tubercles. No. 809 is the calvarium of same patient, showing a number of flattened reticulated osteophytes on its inner surface.]

CASE 867.—George Washington; negro; age 50; admitted August 2, 1866. Chronic diarrhœa. Died, August 4th. *Autopsy* six hours after death: Rigor mortis marked; no emaciation; height five feet two inches and a half; weight about 135 pounds; has lost the last two phalanges of the middle, ring and little fingers of the left hand, (old stumps.) The subarachnoid fluid was unusually abundant. The brain weighed forty-seven ounces and a half; the venous sinuses contained black coagula. There were scattered tubercles in both lungs, with adhesions posteriorly, especially on the right side; the right lung weighed thirteen ounces and a half, the left lung ten ounces. The heart weighed ten ounces and a half; the walls of its left ventricle were hypertrophied, the edges of the tricuspid valve thickened; both sides of the heart contained fibrinous clots. There were extensive peritoneal adhesions. The liver was hard, rounded, and contained a number of metastatic foci in its right lobe; it weighed fifty-six ounces and a half; the gall-bladder was distended with bile. The spleen was very small, its Malpighian bodies distinct. The pancreas was light colored and weighed two ounces. The small intestine was healthy. The colon was thickened and extensively ulcerated, with elevated patches of pseudomembrane between the ulcers. The kidneys weighed five ounces and a half; the cortical substance of both had a waxy appearance; the pyramids were pinkish red.—Assistant Surgeon E. Bentley, U. S. A. [No. 849, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the colon which is much thickened, and presents extensive jagged ulcers from the edges of which the mucous membrane hangs in shreds; there is some adherent pseudomembrane between the ulcers.]

CASE 868.—William Cole; age 45; admitted June 22, 1867. Chronic diarrhœa. The patient was debilitated, his appetite poor and digestion impaired. He had suffered from pleurisy a short time before admission. Died, July 20th. *Autopsy* ten hours after death: Rigor mortis well marked; height five feet ten inches; weight 114 pounds. Pleuritic adhesions existed over the entire external surface of the right lung, the lobes of which were interadherent; there was a melanotic nodule in the middle lobe and some congestion of the lower lobe; slight adhesions were also observed between the lobes of the left lung, and there were a few small melanotic nodules in its lower lobe. The heart was normal; all its cavities contained clots. Forty-five ounces of straw-colored serum were found in the abdominal cavity. All the abdominal viscera were glued together by firm old peritoneal adhesions. The mesentery and the mesocolon were œdematous. The liver exhibited intralobular congestion, and there was a cicatrix on the upper surface of its right lobe. The spleen was dark-red, its capsule easily detached, its Malpighian bodies prominent. The stomach was healthy. The small intestine pale. The mucous membrane of the colon was ulcerated. The sigmoid flexure of the colon extended transversely across the sacro-lumbar articulation into the right iliac fossa, the extreme point of the bend being firmly attached to the cæcum; the mesocolon corresponded in its attachment to this abnormal position. The kidneys presented a number of small superficial cysts.—Hospital Steward D. S. Lamb. [No. 891, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the thickened colon with follicular ulcers, some of which have extended into erosions of moderate size; pseudomembranous shreds hang in fringes from the edges of the ulcers.]

CASE 869.—Richard Tibbs; negro; age 20; admitted November 7, 1866. Died, July 27, 1867. *Autopsy:* Height five feet eight inches; weight 90 pounds. The right lung weighed fifteen ounces; its middle lobe contained a number of miliary tubercles; the left lung weighed seventeen ounces and presented several tubercular cavities. The aorta was atheromatous. The follicles of the duodenum were prominent. The mucous membrane of the ileum was congested; its solitary follicles enlarged; Peyer's patches ulcerated. The mucous membrane of the large intestine was congested and presented minute follicular ulcers and patches of pseudomembrane.—Hospital Steward D. S. Lamb. [No. 969, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the colon with pin-head ulcers of the solitary follicles and pseudomembranous frosting.]

The histories of the ten following cases were forwarded to the Museum, with the specimens, since the close of the war, by the medical officers whose names are attached:

CASE 870.—Private John Churn, company D, 2d United States colored troops; admitted to Harewood hospital, Washington, D. C., January 11, 1866. Typhoid fever. Died, January 12th, at 6 P. M. *Autopsy* forty hours after death: A well-formed negro man, five feet six inches high; weight 130 pounds; slightly emaciated; a large triangular scar on the right thigh about an inch above the knee; rigor mortis well marked. The veins of the pia mater were finely congested; the pia mater readily separated from the convolutions of the brain; the substance of the brain was firm; the lining membrane of the lateral ventricles

was opaque and appeared to be slightly softened; about two drachms of serum were found in each lateral ventricle; the fornix was slightly softened, the choroid plexus very pale; the pineal gland contained a small amount of calcareous matter; the cerebellum was large, its membranes finely congested; there was an accumulation of about three ounces of pinkish serum in the posterior fossæ of the cranium; weight of the brain was not obtained. At the base of the left lung there was a small amount of crude tubercle; the upper lobe was slightly congested, otherwise the lung was normal; the upper lobe and the posterior portion of the inferior lobe of the right lung were slightly congested; the middle lobe was apparently healthy; about three ounces of serum were found in each pleural cavity. The pericardial sac contained about two ounces of clear yellow serum. The heart was very large and flabby; it was dark colored and presented on its surface numerous dark spots, apparently ecchymoses; there were large white fibrinous clots in all the cavities of the heart, ramifying through the pulmonary artery, the aorta and their branches; the tricuspid and mitral valves were somewhat thickened, the aortic valves atheromatous, the columnæ carneæ pale. The liver was large, of a dark bronze color, very firm, and slightly congested; the gall-bladder filled with bile. The spleen was normal in size and very firm, of a dark purple color externally, dark brown internally. The right kidney was very small and fatty; the left was larger than normal, being about three times the size of the right kidney; it was congested and very fatty. The ureters showed no abnormal condition. The omentum was firm, dark and congested; it was contracted into a band. The pancreas was large, very firm, and of a dark color. The stomach, near the cardiac orifice, was much congested; its mucous membrane slightly thickened. The mucous coat of the duodenum was thickened, its upper portion much discolored with bile; near the pylorus the solitary follicles were slightly enlarged. The mucous membrane of the jejunum was slightly thickened and congested. The ileum was covered with pseudomembrane, particularly its lower portion; in the upper portion Peyer's patches were slightly thickened, in the lower portion they presented a few points of commencing ulceration. The mucous membrane of the cæcum and colon was coated with pseudomembrane, greatly thickened, and presented a number of large but superficial ulcers. The urinary organs appeared healthy.—Hospital Steward Samuel S. Bond. [Nos. 698 and 699, Medical Section, Army Medical Museum, are from this case. No. 698 is a portion of the ileum near the ileo-cæcal valve, thickened and roughened by adherent pseudomembrane. No. 699 is a portion of the rectum much thickened; its mucous membrane presents large ulcers and patches of adherent pseudomembrane; between the large ulcers are numerous minute follicular ulcers. It will be observed that the case was really one of dysentery.]

CASE 871.—Recruit Martin Kuster was struck by lightning during a violent thunder storm, while standing under or against a poplar tree near his post on Governor's Island, New York harbor, September 14, 1866. The left side of his cap was torn open, the facing of the metal button of that side thrown off; the hair of the left temple and behind the ears singed and burnt; the left boot was torn widely open from the outside seam forward and upward, and the stocking within it torn, while the right boot was torn open by two small rips in front of the outside seam and about an inch apart, one above the other. No other external marks were observed. His coat was buttoned closely about him; none of its buttons, nor those of his vest or pants, were affected. *Autopsy* sixteen hours after death: A stout muscular man. Some slight purplish stasis was observed at the back part of the neck; partial rigor of the arms, admitting a limited motion at the shoulder and elbow joint; the fingers were quite rigid, as were also the lower extremities; the skin of the left temple and behind the ear was singed away; a faint dull-yellow or amber-colored line extended from half way down the left side of the neck forward to the sternal end of the clavicle, thence irregularly double downward on the left of the median line of the chest over the sternum, more irregularly down the abdomen, passing to the left of the umbilicus, and becoming indistinct just before reaching the hair of the pubes, which was burnt over the middle of the ramus of the left pubis and upon the left side of the scrotum. This yellow line became again distinct upon the inner side of the thigh in a direction downward and backward, was lost over the popliteal space, became again distinct by burnt hairs on the back of the left calf, passed then to the outside and forward to the front of the external malleolus, where it ended. A similar but fainter burnt line of hairs could be traced on the back of the right calf, passing also downward, outward and forward to terminate in front of the external malleolus of that side. A little blood oozed from the left ear. There was some very slight stasis at the lower part of the back. The pupils were widely dilated. The adipose tissue beneath the skin of the chest and abdomen was abundant. On dissection beneath the lines mentioned no change in the fat or on the inside of the cutis vera was observed. The scalp was quite free from blood. No fracture of the skull was found. The subarachnoid space contained no excess of fluid. The longitudinal sinus was noticeably free from blood. Opposite the left parietal protuberance over the two lower convolutions of the parietal lobe, between the fissures of Rolando and Sylvius, there was a marked effusion of blood beneath the membranes; considerable serum was found in the lateral ventricles and in the spinal membranes; the substance of the brain and the choroid plexus appeared to be normal. The trachea was injected and lined with white glistening frothy mucus nearly a quarter of an inch thick. The lungs were dilated, filling the thoracic cavity; the right lung was perfectly free, the left had old pleuritic adhesions posteriorly. There was no effusion into the pleural sacs. The heart was large and fatty, its right cavities filled with black blood. There was much fat at the apex of the heart and at the base of the right ventricle; a white opaque spot was observed on the front of the left ventricle. The intestines were much distended with air, the stomach only moderately so. The stomach was partly filled with food; its rugæ were reddened; at the posterior part of its cardiac end blackened and thinned by post mortem digestion. Partly digested food of a yellowish cream-like appearance was found in the entire length of the small intestine. (He had his supper over an hour before death.) Peyer's patches near the ileo-cæcal valve were reddened so as to be visible externally, somewhat thickened, and slightly honey-combed. The solitary glands were enlarged, especially at the lower end of the ileum. The colon contained normal yellow fæces. The spleen was black and friable, but without fluid blood. The gall-bladder was almost entirely empty. The liver contained some fluid blood, but not a great deal; the bladder was half filled with urine.—Assistant Surgeon W. C. Miner. [Nos. 854 and 855, Medical Section, Army Medical Museum, are from this case. No. 854 is a portion of the ileum presenting a somewhat thickened Peyer's patch and pin-head enlargement of the solitary follicles. No. 855 is a portion of the colon with a number of minute follicular ulcers. The condition of the intestine is similar to that observed in patients who have suffered from slight diarrhœa; but there is no record that this man ever had that disease.]

CASE 872.—Private William Collins, company A, 13th United States Infantry; age 22; single; admitted to post hospital, Fort Shaw, Montana territory, October 11, 1867. Chronic dysentery and abscess of the liver. This man had suffered from attacks of dysenteric diarrhœa and had been on the sick report off and on all summer. During this time he was under the care of Acting Assistant Surgeon R. B. Hitz, U. S. A., and was treated sometimes with pills of camphor and opium, at other times with pills containing each two grains of sulphate of copper and one of opium, three times daily. As a rule he soon got better under this treatment, and returned to duty temporarily, soon to suffer a new attack. He was of temperate habits, and stated that he had heretofore uniformly enjoyed perfect health. At the date of admission into post hospital private Collins was somewhat emaciated; he had frequent watery stools streaked with blood, considerable fever, much thirst, dry furred tongue, and tenderness of the abdomen with pain especially in the left iliac region, and a craving appetite. The functions of the heart, lungs and kidneys were well performed; pulse about 100 and rather weak. Treatment: Enemata containing tannic acid or acetate of lead, with quarter of a grain of sulphate of morphia internally three or four times during the twenty-four hours; also neutral mixture from time to time, and mustard poultices to the abdomen when the pain was very severe. Milk diet, &c. The substitution of opium, with or without astringents, internally, instead of sulphate of morphia, and the omission of the neutral mixture, comprised the treatment up to October 30th. By this time he was evidently weaker, more emaciated than when first admitted, and complained of considerable pain over the right lobe of the liver, which felt smooth and somewhat hard to the touch, with considerable tenderness. ℞. Tincture of catechu half an ounce, aromatic spirits of ammonia a drachm and a half, compound spirits of lavender two drachms and a half, sulphate of morphia one grain and a half, brandy three drachms; mix. Take two teaspoonfuls four times a day, and once or twice at night if necessary. November 3d: Enema of half a grain of sulphate of morphia at night. Previous treatment discontinued. No improvement. Dejections frequent, especially at night; they are watery and tinged with blood; pulse about 100 and weak; there is much pain over the region of the liver; countenance anxious; is much emaciated. November 4th: To take an acetate of lead and opium pill three times a day, and one or two opium pills at night if the bowels are very troublesome. November 6th: Quarter of a grain of sulphate of morphia, to be repeated as may be necessary. November 9th: A grain opium pill three times a day and once at night. During all this time his diet was supporting; he had eggs when they could be obtained, milk-punch, beef-steak, farina, toast, &c., in as great variety as possible to suit his appetite, which had become exceedingly capricious. November 21st: ℞. Tincture of iodine, tincture of opium, tincture of camphor, of each twenty drops, chalk mixture half an ounce, water one ounce. The whole to be taken three times a day and once at night. November 22d: Continue treatment. November 23d: Continue treatment except one-half the quantity of tincture of iodine. November 24th: Continue treatment. November 25th: Continue treatment without the iodine, which was omitted because it commenced to irritate the stomach. Under the iodine treatment the frequency of the stools was somewhat lessened temporarily, but on the whole perhaps this treatment rather injured the patient. I heard Surgeon E. Swift, U. S. A., speak in the highest terms of his success with the use of tincture of iodine in chronic affections of the bowels, and thought best to give it a trial in this case. November 28th: Substitute an acetate of lead and opium pill three times a day and once at night, and give half an ounce of porter whenever desired. November 29th: An opium pill four times a day. Porter continued. The patient prefers porter to any other stimulant. He is evidently failing, and has become emaciated; the stools are frequent. He complains a great deal of pain over the liver and in the left iliac region. Is not jaundiced. December 4th: To take two grains of quinine three times a day; also, three times a day, a pill containing two grains of acetate of lead and half a grain of opium. The patient had for several days appeared a little more comfortable on alternate days, conveying the idea of periodicity; hence the quinine was administered, but with no appreciable benefit. December 7th: Is evidently near his end. Can hardly be induced to take any nourishment. December 9th: Died at 1 A. M., exhausted and emaciated almost to a skeleton. He was not at any time jaundiced. *Autopsy* ten hours after death: The lungs and heart were normal. The right lobe of the liver was the seat of a large abscess, and on the upper surface of the lobe there was a loss of structure beneath the peritoneum, forming a shallow cup-shaped excavation three or four inches in transverse diameter and half to three-quarters of an inch deep; this excavation was filled with pus and communicated with the main cavity of the abscess in the center of the lobe. The mucous membrane of the whole length of the colon was extensively eroded and ulcerated; all the coats were much thickened and altered in structure, so that a section presented a gelatinous appearance; at intervals the tube was much contracted. The peritoneal coat appeared to have been perforated by the ulcers in two or three places just above the sigmoid flexure; the perforations were well closed by strong adhesions resulting from local peritonitis; it was difficult to dissect out the bowel in this region, as the adhesions were quite extensive and well organized. The spleen contained great numbers of small hard nodules [metastatic foci?]. The remaining abdominal organs were apparently healthy.—Surgeon F. L. Town, U. S. A. [Nos. 971 and 972, Medical Section, Army Medical Museum, are from this case. No. 971 is a portion of the colon with many oval and irregular ulcers which invade the muscular coat; there are also several cicatrices. No. 972 is a portion of the liver containing the abscess-cavity described above.]

CASE 873.—Private John Crowley, company G, 6th United States Infantry; admitted to post hospital, Charleston, South Carolina, July 3, 1867. Chronic diarrhœa. Died, November 30th. *Autopsy* eight hours after death: The intestinal canal was found to be inflamed and ulcerated throughout its entire extent. The other organs of the abdomen were healthy.—Assistant Surgeon J. C. G. Happersett, U. S. A. [No. 990, Medical Section, Army Medical Museum, is from this case. This specimen is a portion of the thickened transverse colon which presents numerous follicular ulcers.]

CASE 874.—Musician Ernst Kretschmar; age 39; admitted to post hospital, camp Grant, near Richmond, Virginia, December 24, 1867. Chronic dysentery and consumption. This man had dysentery or diarrhœa since early in October. He was admitted to hospital October 14th suffering with acute diarrhœa, and as he had then only two to four stools in the twenty-four hours, and the hospital was over-full at the time, he was returned to quarters after three days, and ordered to report daily at sick-call. When readmitted, December 24th, he presented the physiognomy of a consumptive, but, in reply to questions, declared that he had no cough, only occasionally a little phlegm in his throat; but that he had a bad diarrhœa, which was most trouble-

some at night. There were from six to eight thin yellow watery stools in the twenty-four hours. He was extremely emaciated and had but little appetite. Although his diarrhœa (or dysentery, as it doubtless was) had continued ever since his discharge from hospital, he had not reported at sick-call or had any medical treatment, and gave no reason for remaining away. Examination of his chest revealed dulness on percussion over the upper part of the right lung and mucous rales on both sides, most prominently above. He said that he had never had hæmoptysis. To take a pill of tannin and opium every two hours; also a tablespoonful of cod-liver oil three times a day. Special diet. December 25th: Five stools in the last twenty-four hours. Continue treatment. December 26th: Four stools. Continue treatment. December 27th: Sleeps badly; sputa scanty but thick and yellow. Continue the cod-liver oil. Substitute for the tannin and opium pills a grain pill of opium every three hours. December 29th: Continue cod-liver oil. Omit pills. December 30th: The diarrhœa is worse. He had nine thin watery yellow stools in the last twenty-four hours. To take a tannin and opium pill every two hours. Eight ounces of milk-punch daily. December 31st: Diarrhœa diminished. Continue treatment. January 1, 1868: Does not like the milk-punch; gave four ounces of sherry-wine instead. Continue pills every three hours, and the cod-liver oil. January 2d, 3d and 4th: Patient is failing. Treatment continued. January 5th: Exhales a peculiar sickly odor somewhat like that in typhus fever. Continue treatment except the pills. Body to be anointed with glycerine, and after four hours to be washed with warm soap and water. January 6th: Continue cod-liver oil and wine. Special diet. January 7th and 8th: Continue treatment. Died, January 9th. *Autopsy* eight hours after death: Very firm old pleuritic adhesions existed on both sides; they were extensive on the left side, and on the right coextensive with the pleura, and held the lungs closely in contact with the thoracic parietes. The upper lobe of the left lung was somewhat studded with miliary tubercles; the lower lobe had a few scattered here and there through its substance; the upper lobe of the right lung was infiltrated with white and yellow tubercles, its apex was in fact solidified by them, except that there was a sinuous cavity of an ounce or two capacity in its posterior part; the middle lobe also contained many tubercles, but still freely admitted air everywhere; there was a small cavity at the contiguous surfaces of the middle and upper lobes, and a very small one near the lower lateral margin of the lower lobe. Five or six of the bronchial glands were tuberculous. The heart was small, empty and flabby; the walls of the left ventricle were rather thin; those of the right ventricle were exceedingly thin, in some places scarcely thicker than the blade of a table-knife. An oval spot the size of a ten-cent piece was seen on the mucous membrane of the lesser curvature of the stomach, apparently a healed ulcer. The mucous membrane of the jejunum was much injected; the rest of the small intestine was healthy. A dozen to twenty large irregular ulcers were found in the colon, a few of them apparently in the process of healing; most of them, however, had jagged excavated edges.—Assistant Surgeon John H. Bartholf, U. S. A. [Nos. 922 and 923, Medical Section, Army Medical Museum, are from this case. No. 922 is a portion of the cæcum and ascending colon; No 923 a portion of the transverse colon; each presents several large irregular granulating ulcers, some of which have partially cicatrized.]

CASE 875.—Charles Gray; mulatto; said to have been a soldier, afterward an officer's servant; admitted to the Washington Asylum, D. C., May 1, 1868. Shortly after admission he received a slight wound over the right supraorbital ridge, followed by symptoms of tetanus, from which, however, he recovered. In the following November, after going about barefoot and being otherwise exposed, he was attacked with pneumonia, and died November 11th. He had no symptoms of any abdominal disease while in hospital, but is supposed to have suffered from diarrhœa during the war. *Autopsy* ten hours after death: Body well developed; rigor mortis well marked; there was a cicatrix on the right side of the forehead. The entire left lung was completely consolidated; the left pleura was coated with a well-defined layer of coagulated lymph; the left pleural sac contained nearly a pint of straw-colored liquid; the right lung was normal. The pericardium contained an ounce of fluid. The heart was normal, with the exception of an opaque spot on the external surface of the right ventricle. A number of well-defined cicatrices were found over the entire surface of the large intestine.—Assistant Surgeon E. Bentley, U. S. A. [No. 1003, Medical Section, Army Medical Museum, is from this case. The specimen consists of a portion of the colon, showing several cicatrices.]

CASE 876.—Private Thomas H. Jones, company F, 5th United States artillery, was being treated for acute diarrhœa when I took charge of the hospital at Fort Adams, Rhode Island, in August, 1870, and improved so much that in September he went home on furlough. After his return he was again admitted to hospital and treated for boils about the anus. These suppurated and the pus burrowed, forming long sinuses, which were laid open. The exposed surfaces did not granulate; the patient became anæmic, lost appetite, and had occasional diarrhœa. Though he had no cough I suspected tuberculosis, as both his parents had died of phthisis. On an examination of his chest the physical signs confirmed my suspicions. He was put on cod-liver oil in small doses combined with opium, but it produced diarrhœa and had to be stopped. He continued to improve and grow worse alternately, each change setting him back a little, until about six weeks before his death, when severe diarrhœa set in which nothing would check, and he died, frightfully emaciated, March 6, 1871. *Autopsy:* There were tubercles in both lungs, and in one of them a small cavity. The liver was much enlarged. Tubercular ulcers were found throughout the ileum. The mesenteric glands were enlarged and cheesy.—Assistant Surgeon W. E. Waters, U. S. A. [Nos. 1076 and 1077, Medical Section, Army Medical Museum, are from this case. No. 1076 is a portion of the ileum presenting on its mucous surface several tubercular ulcers; on the peritoneal surface opposite each ulcer there are a number of minute tubercles. No. 1077 is a group of the enlarged mesenteric glands.]

CASE 877.—Private Henry Fischer, company G, 5th United States cavalry; age 31; admitted to the post hospital, camp Apache, Arizona territory, June 21, 1872. He was a man of large proportions, five feet ten inches in height, with well-developed muscular limbs and apparently great powers of endurance. Though not addicted to habitual intoxication, he was a steady hard drinker, and ate proportionately little food. For several weeks previous to his coming to the post surgeon for treatment he had been working very hard, under the hot Arizona sun, building adobe houses, and had suffered all this time from an exhausting diarrhœa; furthermore, for fear of being placed on sick-report and thereby losing his extra-duty pay, he had neglected to come to the hospital for advice, and had allowed his symptoms to continue unchecked, becoming in consequence weaker and worse, until the interruption of the work of building gave him an opportunity to come up for treatment. On admission he was in a

condition of general debility, with loss of appetite, soft and compressible pulse, no fever, tongue clean and dry, and frequent watery discharges from the bowels, but no abdominal pains. He stated that he had not suffered pain of any consequence since the beginning of his illness, and did not remember having passed blood with the stools at any time. The treatment ordered was rest in bed, beef-tea, milk-punch three times a day, and small frequently repeated doses of laudanum, combined the first day with a little castor oil, and subsequently with wine of ipecacuanha. This treatment was kept up five days without ameliorating the symptoms. On the contrary he became weaker, the diarrhœa more frequent and so harassing as to deprive him of sleep at night. On the 26th the laudanum was discontinued, and a combination of tincture of catechu and chalk mixture substituted. This also proved unavailing, and the watery discharges were so frequent during the following night as to call him out of bed every few minutes. About 3 P. M. on the 27th he began to sink rapidly and to lose power over the sphincters. Frequent stimulation with brandy, ammonia and laudanum was kept up until midnight, but without perceptible effect. He died toward 2.30 A. M. on the 28th. *Autopsy* eight hours after death: Rigor mortis well marked; emaciation moderate. The stomach was healthy and filled with the different fluids which the patient had taken the day before, but which had not been absorbed. The small intestine, and the colon as far as the sigmoid flexure, were healthy, with the exception of a few spots of mild inflammatory injection here and there; the mucous membrane, however, looked flabby and bloodless. The sigmoid flexure of the colon and the rectum were covered with innumerable ulcers, increasing in size from above downward; in the lower part of the rectum the muscular coat was exposed, and what was left of the mucous membrane hung in small shreds; the diseased surface extended nearly two feet from the sphincter ani upward. The liver was somewhat enlarged, but nothing abnormal was detected in the other abdominal organs.—Assistant Surgeon J. B. Girard, U. S. A. [No. 1158, Medical Section, Army Medical Museum, is from this case. The specimen is a portion of the descending colon; a large portion of its mucous membrane is destroyed apparently by the diphtheritic process; in the remaining islets of mucous membrane there are a number of follicular ulcers.]

CASE 878.—Sergeant Peter Low, company B, 14th United States Infantry, *en route* from Fort Laramie, Wyoming territory, on sick leave; admitted to post hospital, Fort D. A. Russell, Wyoming territory, September 23, 1872. Chronic diarrhœa. The patient was said to have been intemperate. He was extremely emaciated and slightly jaundiced. He complained of occasional pain referred to the left hypochondrium, and physical examination indicated considerable enlargement of the liver. He died October 1st. *Autopsy:* The brain and spinal cord were not examined. The thoracic viscera were normal. The liver was greatly enlarged and adhered to the intestines and right kidney; in the right lobe of the liver there was a large abscess which had discharged into the intestinal canal by two openings—the first into the duodenum about four inches from the pylorus, the other into the ascending colon nearly the same distance from the caput coli. The small intestine was apparently healthy, but the colon was ulcerated throughout.—Assistant Surgeon J. V R. Hoff, U. S. A. [Nos. 1149 and 1150, Medical Section, Army Medical Museum, are from this case. No. 1149 consists of a portion of the right lobe of the liver with the right kidney and parts of the ascending colon and duodenum attached. The abscess-cavity in the liver communicates with the colon and duodenum, as described above. The mucous membrane of the cæcum and ascending colon is thickened, and presents follicular ulcers with pseudomembranous frosting between the ulcers. No. 1150 is a portion of the transverse colon presenting similar lesions.]

SECTION IV.

REMARKS ON THE PATHOLOGY AND TREATMENT OF DIARRHŒA AND DYSENTERY.

In this section some general remarks will be offered with regard to the symptoms, morbid anatomy, causes and treatment of diarrhœa and dysentery as observed during the war. The manifold varieties of these diseases may conveniently be grouped under the following heads:

1. *Acute Diarrhœa*, including the cases due to inflammation of the intestinal mucous membrane as well as those in which the intestinal lesion does not progress beyond simple irritation.

2. *Acute Dysentery*, including both the simple inflammatory and the diphtheritic forms.

3. *Chronic Dysentery*, under which head the cases reported during the war as chronic diarrhœa will also be included.

4. *Diarrhœa connected with tubercular ulceration of the intestines.*

This classification is based chiefly upon clinical considerations. All cases of flux in which the frequent liquid stools are unaccompanied by marked tenesmus will be included in the first group; when tenesmus is a prominent symptom the cases will be assigned to the second; and the chronic fluxes will be grouped under the third, whether tenesmus be present or not; the fourth group is established for anatomical reasons, and includes those cases of diarrhœa, occurring chiefly among soldiers suffering from phthisis, in which there is tubercular ulceration of the intestines.

The great majority of the fluxes observed during the war belong to the first three groups, and in the acute cases the distinction here made appears to be of some importance; for, whenever tenesmus was a prominent symptom, the disease was more severe and the danger to life greater. The chronic cases, however, whether tenesmus was present or absent, resembled each other in so many respects that it seems most convenient to consider them under a single head.

A more detailed classification, based upon the anatomical lesions observed in autopsies, might appear desirable, but there are many difficulties in the way of such an undertaking. These difficulties will be encountered, whether the nature of the anatomical changes of the mucous membrane, or the portion of the intestine involved, be taken as the ground of distinction; during life it is not always possible to determine the former, and still more frequently it is impossible to fix the latter, so that no such classification would be of as much practical value to the military surgeon as the less ambitious one here adopted.

1. Acute Diarrhœa.

Under this designation, as already indicated, it is proposed to include those cases in which the intestinal lesion does not progress beyond a mere condition of irritation expressed by increased and modified secretion, as well as those in which there is actual inflammation of the mucous membrane. No practical good result can be attained by separating these conditions; the latter is only a higher degree of the former, and the one passes into the other by insensible degrees. The extremely mild and extremely severe cases differ considerably; but it is difficult to draw a line between them, even when the opportunity is afforded for an examination of the intestine after death, and quite impossible to connect the clinical phenomena with the grade of the morbid process in any very definite way.

This mode of regarding the subject agrees substantially with the views of Bamberger, Richter, Lebert, Niemeyer, and other modern German writers,* who include, under the head of intestinal catarrh, or catarrhal inflammation of the mucous membrane of the intestines, (*Darmkatarrh, Katarrhalische Darmentzündung, Katarrhalische Entzündung der Darmschleimhaut, Darmschleimhautentzündung, etc.,*) both the hyperæmic and inflammatory conditions of any part, or of the whole of the intestinal mucous membrane.

The lesions, whether mild or severe, are most generally seated in the cæcum and colon; but more or less extensive tracts of the small intestine, especially of the ileum, are often involved also.† This statement, which is in complete accord with the best modern pathological observations made in civil life, is quite at variance with an opinion which prevailed very generally among our medical officers at the commencement of the war, and which I have ascertained by personal inquiries is still entertained by very many American physicians. According to this opinion, the small intestine is the part of the alimentary canal particularly concerned in diarrhœa, the large intestine in dysentery; and while diarrhœa is rather to be looked upon as a symptom of several morbid conditions than as a distinct disease, yet, so far as it depends upon irritation or inflammation of the intestinal canal, it is to be referred to the small intestine. It is true that in dysentery the inflammation often extends into the lower part of the small intestine, and in like manner, in diarrhœa, the inflammation of the small intestine may extend into the large; but should any considerable area of the colon be thus involved, the diarrhœa will assume a dysenteric character or pass into actual dysentery.

Roberts—*Handbook of the Theory and Practice of Medicine,* Am. edit., Philadelphia, 1874, p. 689—among recent English writers as having adopted the same view.

† See Niemeyer, *op. cit.,* Bd. I, S. 617. Bamberger, *op. cit.,* S. 338. F. J. V. Broussais—*Histoire des Phlegmasies,* 3me édit., Paris, 1822, Tome III, p. 47—went so far as to declare that the small intestine is rarely involved in diarrhœa: "Il est fort rare de trouver dans les cadavres des diarrhéiques des signes de phlogose à cette portion de la muqueuse qui se déploie dans les intestins grêles." P. Vignes—*Traité Complet de la Dysenterie et de la Diarrhée;* Paris, 1825, p. 328—though not so exclusive, also holds that the large intestine is especially the seat of diarrhœa: "Les causes premières qui donnent naissance aux diarrhées sont une *phlegmasie* toujours moins grande que dans la dysenterie, ou simplement *irritation* ou une *atonie du canal intestinal,* particulièrement des gros intestins; mais ces causes peuvent s'étendre aussi dans tout le reste du trajet alimentaire." Consult also F. G. Boisseau, *Nosographie Organique;* Paris, 1828, Tome I, p. 587. J. Bouillaud, *Traité de Nosographie Médicale;* Paris, 1846, Tome III, who writes: "Colite intense ou dysenterie," p. 178; "Colite légère ou diarrhée," p. 184. John Armstrong, *Acute and Chronic Diseases;* Bell's Am. edit., Philadelphia, 1837, p. 303. J. F. H. Albers, *Erläuterungen zu dem Atlasse der Pathologischen Anatomie;* Bona, 1847–'57, Abth. IV, p. 172, and S. O. Habershon—*Diseases of the Abdomen;* 2d edit., London, 1862, p. 362:—"It arises generally from an irritated condition of the large intestine."—p. 365—"Catarrhal and mucous diarrhœa arise from a slight inflammatory disease closely allied to ordinary coryza, affecting the mucous membrane of the *large* intestine."

This error, which is a purely scholastic one, unsupported by anatomical observations, would appear to have resulted from the confusion which still exists in medical literature as to the proper signification of the word Enteritis, a term unknown to the ancients, which was employed by the nosologists of the eighteenth century to represent a group of symptoms which we now recognize as belonging in fact to peritonitis.*

It is true that Cullen made two species of enteritis, *e. phlegmonodœa* and *e. erythematica*, referring the latter to the mucous membrane of the intestine and the subjacent cellular tissue;† but in his chapter on enteritis in his First Lines of the Practice of Physic, he treats only of the phlegmonic variety, and gives a description of it which is applicable to peritonitis alone.‡ The great influence of his opinions gave permanence to this view, so that local peritonitis was long described under the name of enteritis by British and American writers.§

---

* Prior to the nosologists such terms as *inflammatio intestinorum*, *inflammation des boyaux*, &c., were used to designate these symptoms. Compare, for example, SENNERTUS, whose description of *inflammatio intestinorum* agrees substantially with the definition of enteritis given by Sauvages, and clearly applies to peritonitis.—DANIEL SENNERT, *Practicæ Medicinæ* Lib. III, Part II, Sect. I, Cap. II; *De Inflammatione Intestinorum*, Opera, Paris, 1641, Tome III, p. 73. BONETUS, in the *Sepulchretum*, records several autopsies in cases of inflammation of the ileum and colon, in which peritonitis plays a conspicuous part.—THEOPHILUS BONET, *Sepulchretum*, Geneva, 1679, Lib. III, Sectio XIV; *De Ventris dolore, Colico, Iliaco*, etc., Obs. VII and XIX. They are associated with cases of colic, ileus, hernia, &c. In the case of *Febris acuta ab intestinorum inflammatione*, given at length in Lib. IV, Sect. I, Obs. XXXIII, there was perforation of the intestine and general peritonitis.—HOFFMANN, in his chapter on *Febris Intestinorum*, includes inflammations of the mesentery as well as of the intestinal peritoneum.—FREDERICK HOFFMANN, *Medicinæ Rationalis Systematicæ* Tom. IV, Pars I, Sec. II, Cap. XII; *De febre intestinorum inflammatoria ex mesenterio*, Opera, Geneva, 1740, Tom. II, p. 170. BOERHAAVE, in his Aphorisms, gives an account of the symptoms produced by inflammation of the intestines, which includes both peritonitis and ileus.—GÉRARD VAN SWIETEN, *Commentaria in Hermanni Boerhaave Aphorismos, de Cognoscendis et Curandis Morbis*, Paris, 1758, Tom. III, p. 159. See also, as illustrating the ideas prevalent about the middle of the last century, MEYSEREY, *La Médecine d'Armée*, Paris, 1754, Art. 365-'8; *De l'Inflammation des Intestins*, Tome II, p. 365. MORGAGNI, in his two epistles, *De intestinorum dolore*, describes cases of hernia, ileus, biliary calculi, worms, &c., and, toward the close of epistle 35, discusses inflammation of the intestines in a manner which shows that peritonitis was embraced in his conception of the subject.—JOHN BAPTIST MORGAGNI, *De Sedibus et Causis Morborum per Anatomen indagatis*, Lib. III, Epists. 34 and 35, Ebroduni in Helvetia, 1779, Tom. II, p. 155 *et seq.* Several observations, in which the lesions of chronic peritonitis are described, will also be found in the 38th and 39th epistles; but this great observer did not recognize peritonitis as a distinct affection. SAUVAGES, the first of the nosologists, in his definition of enteritis, lays most stress on symptoms which belong to peritonitis.—FRANCISCO BOISSIER DE SAUVAGES, *Nosologia Methodica*, Amsterdam, 1763, Tom. II, p. 463; also, editio ultima, Amsterdam, 1768, Tom. I, p. 478. In the first edition he made four species of enteritis: e. iliaca, e. colica, e. flatulenta, e. mesenterica; to these, in the later edition, e. enterocelica—(strangulated hernia)—is added. Sauvages gives a separate place to epiploitis or inflammation of the omentum, but does not name peritonitis in his nosology. LINNÆUS (1763) separated proctitis from enteritis, but makes no mention of peritonitis.—CHARLES LINNÆUS, *Genera Morborum*, Hamburg and Gustrow, 1773, p. 13. R. A. VOGEL (1764) gives, besides enteritis, mesenteritis, omentitis, myocoilitis and peritonitis. I have not seen an original copy of Vogel's Nosology, and quote from the *Apparatus ad Nosologiam Methodicam* of Cullen, editio nova, Amsterdam, 1775, p. 95. J. B. M. SAGAR, (1771,) following Sauvages, distinguishes enteritis and epiploitis, but does not mention peritonitis.—*Systema Morborum Symptomaticum*, Vienna, 1776, p. 641.

† WILLIAM CULLEN, *Nosologia Methodica*, 3d edit.; by John Thomson, Edinburgh, 1820, p. 55. Cullen does not appear to have made this distinction in the earlier editions of his Nosology, (1769 and 1772,) for I find in the Amsterdam edition of 1775 the species given as 1. Idiopathicæ; 2. Symptomaticæ.—*Apparatus ad Nosologiam Methodicam, seu Synopsis Nosologiæ Methodicæ*, Amsterdam, 1775, p. 172. In the earliest edition of his *First Lines of the Practice of Physic*, Edinburgh, 1778, Vol. I, p. 308, he subdivided idiopathic enteritis into phlegmonic and erysipelatous. The latter term is, however, replaced by the word erythematic in the edition of 1784, Vol. I, p. 372, and in subsequent editions of both the Nosology and the First Lines.

‡ Consult *First Lines*, edit. of 1778, Vol. I, p. 308, and subsequent editions. Following Vogel, Cullen included peritonitis in his Nosology, but did not describe it in his *First Lines*, "because we cannot say by what symptoms they are always to be known; and farther, because, when known, they do not require any remedies besides those of inflammation in general."—*Op. cit.*, Vol. I, p. 293, and subsequent editions. The vague character of the notions of peritonitis generally prevailing at the time may be illustrated from the remarks of ERASMUS DARWIN in the *Zoonomia*, (1794-'6,) that "it has probably most frequently a rheumatic origin." I quote from the Philadelphia edition of 1797, Part II, Chap. II, Order 1, Gen. 8, p. 250. In this work no definition is offered of either peritonitis or enteritis; indeed, the definitions of very many diseases are omitted because they "may be seen in the Nosologia Methodica of Sauvages, and in the Synopsis Nosologiæ of Dr. Cullen." [See Preface to Part II.] The first distinct mention which I find of inflammation of the peritoneum as an affection independent of inflammation of the subjacent parts is by JOHN HUNTER—*A treatise on the Blood, Inflammation, and Gunshot Wounds*, London, 1794, p. 244—who compares peritonitis to pleurisy, which had long been recognized as a distinct affection. Hunter, in fact, was the first to point out clearly the differences between inflammation of the serous and mucous membranes.—*Op. cit.*, p. 241, &c.

§ Among the British writers who followed Cullen's views of enteritis most closely, I may cite: BARTHOLOMEW PARR, *The London Medical Dictionary*, (1809,) American edit., Philadelphia, 1819, Art. Enteritis, Vol. I, p. 805. THOMAS YOUNG—*An Introduction to Medical Literature, including a System of Practical Nosology*, London, 1813, p. 228—who uses the term *cauma enteritis*, cauma signifying inflammatory fever. JOHN MASON GOOD—*The Study of Medicine, with a Physiological System of Nosology*, (1817,) 4th American edit., Philadelphia, 1825, Vol. II, p. 256, Vol. V, p. 141—who uses the term *empresma enteritis*, the word empresma being employed as the generic term for internal or visceral inflammation; and calls Cullen's e. phlegmonodea, e. adhæsiva. GEORGE GREGORY—*Elements of the Theory and Practice of Physic*, 2d American from the 3d London edit., Philadelphia, 1829, p. 451—who formally defines enteritis as "inflammation of the peritoneal coat of the intestines;" but has a chapter also (p. 457) on "inflammation of the mucous membrane of the alimentary canal," and in a note to the section on "inflammation of the mucous membrane of the small intestines," suggests, "*enteritis mucosa* is perhaps its legitimate denomination." JOHN ABERCROMBIE—*Pathological and Practical Researches on Diseases of the Stomach, the Intestinal Canal, the Liver and other Viscera of the Abdomen*, Edinburgh, 1828, p. 149—who describes peritonitis and inflammation of the mucous membrane of the intestines separately, and limits the term enteritis to those cases in which the inflammation affects "the peritoneal and muscular coats at once." JOHN ELLIOTSON—*The Principles and Practice of Medicine*, 2d edit., London, 1846, p. 1047—whose description of enteritis corresponds strictly with the phlegmonous variety of Cullen. HERBERT MAYO—*Outlines of Human Pathology*, American edit., Philadelphia, 1841, p. 235—who takes the same view of enteritis, describes also inflammation of the intestinal mucous membrane, the acute form of which he tells us is extremely rare; and THOMAS WATSON—*Lectures on the Principles and Practice of Physic*, new American edit., Philadelphia, 1858, p. 886—who, in his lecture on enteritis, describes only the phlegmonous variety of Cullen. Among the American writers I may mention JAMES THACHER, *American Modern Practice*, Boston, 1817, p. 449; also *Ib.*, new edit., Boston, 1826, p. 388; in this edition the author adopts Hosack's Nosology, Preface, p. VII. JOSEPH A. GALLUP—*Outlines*

In France, on the other hand, near the close of the last century, the use of the word enteritis was limited by Pinel, in his *Nosographie Philosophique*, to inflammation of the intestinal mucous membrane, a usage which soon became general among the French writers, and, in consequence of the growing influence of the French school, was extensively adopted in other countries.*

The prevalence of this view had the effect of giving prominence in certain quarters to that dual conception of enteritis which Cullen had propounded in his Nosology, but had failed to establish on a firm foundation. Inflammations of the peritoneal and of the mucous coats of the intestines were described as two varieties of enteritis, and the attempt was thus made to reconcile the observations of the pathological anatomists with the teachings of the nosologists.†

Meanwhile, a limitation of the term yet narrower than that made by Pinel was proposed by Broussais, who, in the *Propositions de Médecine* prefixed to his *Examen des Doctrines Médicales*, restricted enteritis to inflammation of the mucous membrane of the

---

of the Institutes of Medicine, Boston, 1839, Vol. II, p. 95—who defines enteritis as "inflammation of the fibro-muscular coat of the intestines." DAVID HOSACK, *A System of Practical Nosology*, 2d edit., New York, 1821, p. 212; and N. CHAPMAN, *Lectures on the more Important Diseases of the Thoracic and Abdominal Viscera*, Philadelphia, 1844, p. 255. Chapman teaches that enteritis ordinarily involves all the coats, and that "an exclusive mucous phlogosis is exhibited, perhaps, only in mild diarrhœa, and even here it is among the rarest of events."

* PHILIPPE PINEL—*Nosographie Philosophique*, (1798,) 6me édit., Paris, 1818, Tome II, p. 306.— In his first edition Pinel separated inflammations of the mucous from those of the diaphanous membranes, (which in subsequent editions, following Bichat, he called serous,) and placed enteritis among the former, peritonitis among the latter. BROUSSAIS, however, has pointed out—*Examen des Doctrines Médicales*, Paris, 1821, Tome II, p. 475—that, notwithstanding this distinction, in describing enteritis he ascribes to it the symptoms of peritonitis. I note that this error is not fully corrected in the later editions, and that although catarrhal diarrhœa and dysentery are included by Pinel among the phlegmasiæ of the mucous membranes, they are described separately, and not under the head of enteritis. CHOMEL—*Dictionnaire de Médecine*, 2d édit., Tome XXIII, Paris, 1841, p. 559—has claimed the credit of correctly distinguishing between enteritis and peritonitis for Bichat; but even ANTOINE MIQUEL—*Éloge de Xavier Bichat*, Paris, 1823, note 19, p. 72—who so passionately blames Broussais for ascribing the distinction to Hunter, as he correctly does—*Loc. cit.*; also Tome I, p. 298—and who has pointed out the great influence which the *Anatomie Générale* had upon the subsequent edition of the Nosographie Philosophique, is obliged, by the date of the first edition, to give the priority to Pinel rather than to Bichat. Bichat himself tells us that it was the perusal of Pinel's work which suggested his treatise on the membranes, the germ of the Anatomie Générale.—XAVIER BICHAT, *Traité des Membranes*, (1800,) nouv. édit., Paris, 1827, p. 4. A good account of peritonitis, with a brief sketch of intestinal catarrh, will be found in Bichat's *Anatomie Pathologique*, Paris, 1825. It is, however, doubtful how far this work, published more than twenty years after the death of its reputed author, from a manuscript purporting to contain notes of his lectures, really represents his views. [See the introductory notice by Boisseau, prefixed to the work.] Among the continental authors who followed Pinel in using the term enteritis to signify inflammation of the mucous membrane of any portion of the intestinal canal from the pylorus to the anus, I may cite: RENAULDIN, Art. *Entérite*, in the *Dictionnaire des Sciences Médicales*, Tome XII, Paris, 1815, p. 361. DALMAS, Art. *Entérite*, in the *Dictionnaire de Médecine*, 2me édit., Tome XVII, Paris, 1838, p. 33. J. BÉHIER et A. HARDY—*Traité Élémentaire de Pathologie Interne*, 2me édit., Tome II, Paris, 1864, par. I, p. 333—who follow the statement "à proprement parler, le mot entérite désigne particulièrement l'inflammation des intestins grêles" by the remark "nous croyons devoir laisser à l'entérite son acception la plus large;" and RUD. LEUBUSCHER—*Handbuch der Medicinischen Klinik*, Leipzig, 1859, Bd. I, S. 480—who, however, although he uses the term enteritis as the equivalent of inflammation of the mucous membrane of any portion of the intestinal canal, giving a general description of a catarrhal and diphtheritic form, subsequently describes separately: 1, Catarrh and inflammation of the duodenum and the ileum; 2, of the colon; 3, of the cæcum; 4, of the rectum; and 5, dysentery. Among British and American writers I may name: DAVID CRAIGIE—*Elements of the Practice of Physic*, Edinburgh, 1837, Vol. I, p. 893, and Vol. II, (1840,) p. 171—who proposed the term *enteria* to distinguish inflammation of any part of the intestines, and refers the enteritis of Cullen and the nosologists to peritonitis. WILLIAM P. DEWEES—*Practice of Physic*, 2d edit., Philadelphia, 1833, p. 594—who remarks: "By enteritis we are to understand an inflammation of *the internal coat of the intestines*. We have emphasized 'the internal coat of the intestines,' as Good and Gregory, two of the latest British writers on Practical Medicine, seem to have confounded peritonitis with enteritis; a mistake of great pathological and therapeutical consequence." JOHN MACKINTOSH—*Principles of Pathology and Practice of Physic*, 2d American edit., Philadelphia, 1837, Vol. I, p. 344—who says: "Inflammation of the mucous membrane of the bowels, (enteritis,)" &c.

† Consult, for example: C. F. TACHERON—*Recherches Anatomico-Pathologiques sur la Médecine Pratique*, Paris, 1823, Tome II, p. 419—"L'entérite est l'inflammation de la totalité ou seulement d'une partie de la muqueuse intestinale, ou de toute l'épaisseur des intestins grêles ou gros." CHOMEL—Art. *Entérite, Nouveau Dictionnaire de Médecine, Chirurgie, etc.*, Tome I, Paris, 1826, p. 678—who divides enteritis into 1, *e. superficielle*, or diarrhœa; 2, *e. profonde ou phlegmoneuse;* and 3, *dysenterie*. The author of the article *Entérite* in the *Dictionnaire des Dictionnaires de Médecine*, Tome III, Paris, 1840, p. 582, who divides it into *e. phlegmoneuse* and *e. muqueuse*, subdividing the latter into *e. villeuse, e. folliculeuse*, and *e. pseudo-membraneuse*. H. BRESSLER—*Die Krankheiten des Magens und Darmkanals*, Berlin, 1841, S. 295—who describes *e. peritonæo muscularis* after Abercrombie, and *e. mucosa* after Scoutetten. Compare also the following British and American authors: JOHN ARMSTRONG—*Lectures on the Morbid Anatomy, Nature, and Treatment of Acute and Chronic Diseases*, Bell's Am. edit., Philadelphia, 1837—who describes muco-enteritis (p. 302) and sero-enteritis, (p. 309,) subdividing the former into muco-enteritis of the small intestines, and of the large, and including diarrhœa and dysentery under the last head. See also IB., *The Morbid Anatomy of the Stomach, Bowels, and Liver*, London, 1838, p. 71: "Inflammation of the serous membrane of the bowels is very frequent in this country, and is, in the majority of examples, unconnected with inflammation of the mucous texture." In this work there are six quarto colored plates to represent the morbid appearances of sero-enteritis; of these, two represent ordinary peritonitis; one, "that peculiar state of bowels called hemorrhagic," "in which all the textures are highly engorged with blood of a remarkably rich dark-purple color;" one is an intussusception of the bowel; one is typhoid ulceration and perforation, with peritonitis; and one tubercles of the peritoneum. MARSHALL HALL—*Principles of the Theory and Practice of Medicine*, London, 1837—who describes sero-enteritis under the head of enteritis: "The morbid anatomy in enteritis consists chiefly in the deposit of layers of lymph upon the intestine, leading to adhesions," p. 378, and proposed to distinguish inflammation of the intestinal mucous membrane as eso-enteritis; acute eso-enteritis he divides into membranous and glandular. JOHN EBERLE—*Practice of Medicine*, 2d edit., Philadelphia, 1831, Vol. I, p. 197—who describes separately peritoneal enteritis and mucous enteritis; and EDWIN R. MAXSON—*A Treatise on the Practice of Medicine*, Philadelphia, 1861—who describes peritoneal enteritis (p. 354) and mucous enteritis, (p. 356:) "By mucous enteritis, I mean here inflammation of the mucous membrane of the small intestines, including the duodenum, jejunum and ileum; and also of the large intestines, if not attended with griping pains in the lower portion of the abdomen, and mucous or bloody evacuations."

small intestine, and bestowed the designation *colite* upon that of the colon.* It is not wonderful that, during the season of almost universal popularity which the doctrines of Broussais enjoyed, this distinction should have been generally adopted; but it has survived the fall of Broussaisism, and continues to find favor in many quarters at the present day.

Some of those who adopted this limitation of enteritis also divided it into a peritoneal and a mucous variety,† while others, who continued to use the term as Pinel did, for

---

*F. J. V. BROUSSAIS—*Examen des Doctrines Médicales et des Systèmes de Nosologie*, Paris, 1821, Tome I; also *Commentaires des Propositions de Pathologie*, Paris, 1829, Tome I, pp. 201 and 212: "*Prop. CXXXI. L'inflammation de la membrane muqueuse des intestins grêles s'appelle entérite.*" "*Prop. CXXXV. Le mot entérite étant consacré a l'inflammation de l'intestin grêle, ne peut servir à distinguer celle du colon; il faut appeler celle-ci colite.*" The combination of gastritis with enteritis Broussais called *gastro-entérite*—Props. 130 and 131—and supposed it to constitute the real lesion in both continued and intermittent fevers.—Props. 139 and 222. In his earlier writings Broussais used the term, as Pinel did, for inflammation of the large intestine also: "La phlogose de la muqueuse du colon, que j'appellerai entérite," &c.—*Histoire des Phlegmasies*, 2d édit., Paris, 1816, Tome II, p. 218. In the 3d edition (Tome III, Paris, 1822, p. 49) the author adds the following note to this passage: "Le nom de *colite* lui convient mieux; il est même indispensable pour la distinguer de l'inflammation des intestins grêles. (*Voyez l'Examen des Doctrines.*) L'entérite, d'ailleurs se complique souvent avec la colite." S. O. HABERSHON—*Diseases of the Abdomen*, 2d edit., London, 1862, p. 268—has singularly perverted the meaning of this passage: "There has been considerable confusion in the application of the term enteritis; Broussais considered it to be inflammation of the colon," &c. Before Broussais, C. A. PERROTEAU—*Dissertation sur l'Entérite Chronique, ou Inflammation lente des Intestins grêles*, Paris, 1801, p. 1, (Paris Theses No. 30)—had described chronic inflammation of the small intestine under the designation of chronic enteritis: "J'entends par entérite ileaque lente, ou simplement entérite lente, entérite chronique, une phlegmasie de l'iléon ou du jéjunum," &c. I do not, however, understand him to propose to limit the use of the word enteritis to the variety which he described. The influence of Broussais' ideas on this subject may be observed in several of the Paris Theses as early as 1818. As for example: M. G. GRESET—*Dissertation sur l'Entérite Chronique ou Inflammation lente des Intestins grêles*, Paris Theses No. 53, 1818, p. 7: "L'entérite est l'inflammation de la membrane muqueuse des intestins. Il en est de plusieurs sortes: 1. l'entérite proprement dite, mot assigné à l'inflammation des portions supérieures du tube intestinal; 2. la diarrhée et la dysenterie, qui sont dues à l'inflammation des portions inférieures," &c. This thesis is dedicated to Broussais, who was then, and had been for several years, professor in l'Hôpital Militaire d'Instruction. Consult also F. J. BOULLARD, *Dissertation sur les Inflammations de la Membrane Muqueuse de l'Estomac et des Intestins grêles*, Paris Theses No. 110, 1818; and J. J. A. LE BATTEUX, *Essai sur l'Inflammation aiguë de l'Intestin grêle*, Paris Theses No. 176, 1820. I note among those who followed Broussais in dividing the phlegmasiæ of the alimentary canal below the diaphragm into gastrite, entérite and colite, with their association together, especially as gastro-entérite and entéro-colite, the following French authors: M. L. ROSTAN, *Traité Élementaire de Diagnostic, &c.*, Paris, 1826, Tome II, p. 489. F. G. BOISSEAU, *Nosographie Organique*, Paris, 1828, Tome I, p. 514. L. CH. ROCHE, Art. *Entérite* in the *Dictionnaire de Médecine et de Chirurgie Pratiques*, Paris, 1831, Tome VII, p. 291: "Ce nom s'applique presque exclusivement à l'inflammation de la membrane muqueuse des intestins grêles." See also L. CH. ROCHE, L. J. SANSON *et* A. LENOIR—*Nouveaux Éléments de Pathologie Medico-Chirurgicale*, (1828,) 4me édit., Paris, 1844, Tome I, p. 466. G. ANDRAL—*Cours de Pathologie Interne*, Paris, 1836, Tome I—who describes gastro-entérite, p. 7, and entéro-colite, p. 72; the latter term, however, is used as the equivalent of l'entérite chronique. *Bibliothèque du Médecin Praticien;* Par une Société de Médecins, sous la direction du DR. FABRE, Paris, 1849, Tome XI, p. 492, Art. Inflammation des Intestins: "Nous diviserons l'entérite en aiguë et en chronique réunissant sous le même titre les inflammations des diverses parties de l'intestin grêle." F. L. I. VALLEIX, *Guide du Médecin Praticien*, 5me édit., Paris, 1866, Tome IV, p. 20. This author, however, inclines to a somewhat more liberal view: "Pour nous *l'entérite* est l'inflammation de l'intestin grêle qui s'étend ou non au gros intestin." A. GRISOLLE—*Traité de Pathologie Interne*, 9me édit., Paris, 1869, Tome I, p. 305: "Le mot entérite semblerait devoir exprimer toute inflammation siégeant sur un point quelconque de la membrane muqueuse du tube intestinal; mais l'usage l'a surtout consacré pour désigner la phlegmasie de l'intestin grêle, et surtout celle qui occupe le jéjunum et l'iléon." Among the German authors who adopted a similar limitation I may mention: CARL GEORG NEUMANN—*Von den Krankheiten des Menschen*, Berlin, 1836-'44—who, though he does not formally use the word enteritis, describes separately "Entzündung der dünnen Därme," Bd. I, S. 237, and Entzündung der Dickdärme, Bd. I, S. 271. CONRAD HEINRICH FUCHS—*Lehrbuch der Speciellen Nosologie und Therapie*, Göttingen, 1846, Bd. II, Abth. 1, S. 425—who uses enteritis as the equivalent of *Dünndarmentzündung*. C. A. WUNDERLICH—*Handbuch der Pathologie und Therapie*, Stuttgart, 2te auflage, 1856, Bd. III, S. 178 *et seq.*—who describes separately inflammations of the small intestine, cæcum, colon and rectum, and only uses the term enteritis in connection with the small intestine. CARL KISSEL—*Denkwürdigkeiten aus der Ärztlichen Praxis*, Berlin, 1872, S. 604—who enumerates enteritis, perityphlitis, typhlitis, colitis and proctitis. I note also the following American and British authors as adhering to Broussais' limitation of enteritis: GEORGE B. WOOD—*Practice of Medicine*, 6th edit., Philadelphia, 1866, Vol. I, p. 703: "Enteritis, then, as employed in this work, signifies inflammation of the mucous membrane of the jejunum and ileum, extending frequently to a greater or less distance into the colon, and occasionally involving the other coats as a secondary result. The force of the disease is usually spent upon the ileum; the jejunum being less liable to inflammation than any other portion of the alimentary canal." "As the inflammation may extend indefinitely into the colon, it is obvious that the phenomena of dysentery must often be mingled with those of the complaint under consideration." WILLIAM AITKEN—*The Science and Practice of Medicine*, 3d American edit., Philadelphia, 1872, Vol. II, p. 628: "Enteritis. Definition: Inflammation of the small intestines." "Although enteritis is generally described in text books, as a rule it is a rare disease, and seldom affects the intestine throughout its whole extent." AUSTIN FLINT—*Principles and Practice of Medicine*, 4th edit., Philadelphia, 1873, p. 383: "Inflammation of the mucous membrane of the small intestines is designated enteritis."

†Thus, for example, JAMES COPLAND—*Dictionary of Practical Medicine*, Vol. II, London, 1844, article *Intestine*, p. 568—describes separately, 1, Inflammation of the small intestines—enteritis; 2, Inflammation of the large intestines—colitis; 3, Inflammation of both small and large intestines—ileo-colitis. Enteritis he divides into inflammation of the mucous surface—muco-enteritis; inflammation of the glands—glandular enteritis, (the lesion of typhoid fever;) and inflammation of all of the coats, the enteritis phlegmonodœa of Cullen. J. L. SCHÖNLEIN—*Allgemeine und Specielle Pathologie und Therapie*, 6te auflage, St. Gallen, 1846, Theil. I, S. 226—describes "*Entzündung des Dünndarms.* Enteritis." "Erste Art. e. serosa." "Zweite Art. e. mucosa." S. O. HABERSHON—*Diseases of the Aldomen*, 2d edit., London, 1862, p. 268—also uses the term only for inflammation of the small intestine, and remarks: "Enteritis, then, manifests itself under two forms: 1, That involving only the mucous membrane, and which has a disposition to extend in the course of the mucous membrane—muco-enteritis; and, 2, That in which the disease extends in depth, rather than on the surface, and implicates the muscular, peritoneal coats, and the connecting tissues: both commence in the mucous membrane." To these I may add J. M. DA COSTA—*Medical Diagnosis*, 3d edit., Philadelphia, 1870, p. 472—who remarks: "Enteritis means now, by common consent, inflammation of the small intestine, and especially of the portion that lies between the duodenum and the colon. The morbid process may extend to the colon; if, however, it involve a large portion of the latter, it is colitis or dysentery, and not enteritis with which we have to deal. There are two forms of enteritis: one in which the mucous membrane of the bowel is alone affected; the muco-enteritis, or the catarrhal inflammation of recent authors, the erythematous enteritis of Cullen. In the second, more than the mucous tunic is implicated; there is also inflammation of the submucous and muscular coats, or even of the serous investment of the bowels. To this variety of the complaint the term enteritis is by several writers restricted; and it is to this form of the malady, occurring acutely, that the description about to be given more particularly applies;" and JOHN SYER BRISTOWE—Art. *Enteritis*, in *Reynold's System of Medicine*, Vol. III, London, 1871, p. 56—who subdivides the disease as follows: I. As affecting the serous and muscular coats. II. As affecting the mucous membrane: a. catarrhal inflammation; b. croupous inflammation; c. chronic inflammation and degeneration. III. As affecting the whole thickness of the bowel.

inflammation of the mucous membrane of all portions of the intestines, have nevertheless attempted to discriminate varieties corresponding to the several portions of the intestinal canal—duodenitis, jejunitis, ileitis, typhlitis, colitis and proctitis—and exercised themselves in the attempt to find symptoms which might enable the practitioner to diagnosticate during life the portion of the intestine affected.*

The confusion which has resulted from these diverse conceptions of enteritis has been still further increased by the circumstance, which will be referred to more fully in a subsequent chapter, that cases characterized by the lesion of the agminated glands of the small intestine peculiar to typhoid fever were universally included under the head of enteritis at the beginning of the present century, and continued to appear in many systematic treatises as a variety of enteritis (*entérite folliculeuse*, glandular enteritis, &c.) long after the relation of this lesion to a particular febrile disease was fully established.† Moreover, it has unfortunately happened that a number of the authors who followed Broussais in defining enteritis as limited to the mucous membrane of the small intestine, continued to ascribe to it the symptoms which had been detailed by those who used the term in its broader signification, and the misconceptions thus countenanced have been the more mischievous, because in many modern English and American treatises the question of the real nature of the intestinal lesion in acute diarrhœa is either very imperfectly discussed or altogether neglected; and because the disease so rarely terminates fatally in civil life that the opportunities afforded for post mortem examinations are comparatively infrequent.‡ Perhaps it is on account of the latter circumstance chiefly, that some systematic writers have gone so far as to propose to strike diarrhœa from the list of diseases, regarding it as a mere symptom of a number of pathological conditions,§ among which it is true they include irritation

---

*For example: WILLIAM STOKES—Article *Enteritis*, *Cyclopædia of Practical Medicine*, American edit., Philadelphia, 1845, Vol. II, p. 46—includes, under enteritis, duodenitis, inflammation of the jejunum and ileum, inflammation of the cæcum, inflammation of the appendix vermiformis, and colitis. Substantially the same views are expressed in his *Lectures on the Theory and Practice of Physic*, 1st American edit., Philadelphia, 1837, p. 59. So also ROBLEY DUNGLISON—*The Practice of Medicine*, Philadelphia, 1842, Vol. I, p. 102—divides enteritis into 1, Inflammation of the small intestines; 2, Inflammation of the large intestines. The first he subdivides into—a, inflammation of the peritoneal coat; b, inflammation of the mucous coat; c, exanthematous inflammation of the mucous coat; the second into—a, inflammation of the cæcum; b, of the appendix vermiformis cæci; c, of the colon, (1, of the peritoneal coat of the colon; 2, of the mucous coat.) Compare also ERNST A. L. HÜBENER—*Specielle Pathologie und Therapie*, Erlangen, 1850, Bd. I, S. 407—"Enteritis ist der Collectivname für sämmtliche Darmentzündungen." "Je nachdem dieses oder jenes Gewebe des Darms afficirt ist, theilte man die Enteritis in eine muscularis, mucosa und serosa, letztere wieder in eine villosa und follicularis." He describes—1, Duodenitis; 2, Ileitis; 3, Typhlitis; 4, Colitis; 5, Proctitis; and SAMUEL HENRY DICKSON—*Elements of Medicine*, Philadelphia, 1855, p. 470—who also includes duodenitis, ileitis, typhlitis and colonitis under the head of enteritis, but defines the disease as limited to the mucous membrane.

†See, for example: GREGORY, work cited on page 267, Vol. I, p. 463. CHAPMAN, work cited on page 268, p. 260. CRAIGIE, work cited on page 268, Vol. I, p. 899. TACHERON, work cited on page 268, Tome II, p. 495. A. N. GENDRIN, *Histoire Anatomique des Inflammations*, Paris, 1826, Tome I, p. 587: "Phlegmasies pustuleuses des membranes muqueuses et des membranes villeuses." C. A. PERROTEAU, *Diss. sur l'Entérite Chronique*, Paris, 1801. C. P. FORGET, *Traité de l'Entérite Folliculeuse, (fièvre typhoïde,)* Paris, 1841. J. BOUILLAUD, *Traité de Nosographie Médicale*, Paris, 1846, Tome III, p. 92. F. G. BOISSEAU, *Nosographie Organique*, Paris, 1828, Tome I, p. 518. L. CH. ROCHE, Art. *Entérite, Dict. de Méd. et de Chir. Pratiques*, Paris, 1831, Tome VII, p. 299: "Entérite folliculeuse." JAMES COPLAND, *Dictionary of Practical Medicine*, London, 1844, Vol. II, p. 571: "Glandular Enteritis." W. STOKES, Art. *Enteritis, Cyclopædia of Practical Medicine*, Philadelphia, 1845, Vol. II, p. 53. SCOUTETTEN, "Des follicules de la membrane muqueuse du tube digestif sous le rapport anatomique, physiologique et pathologique," in *Jour. Comp. du Dict. des Sciences Médicales*, Tome 29, Paris, 1827, p. 200: "Ainsi désormais l'inflammation de la membrane muqueuse de l'estomac et de l'intestin ne sera plus divisée qu'en gastro-entérite folliculeuse, et gastro-entérite villeuse." M. L. ROSTAN, *Traite Élémentaire de Diagnostic*, etc., Paris, 1826, Tome II, p. 497: "Entérite avec éruption furonculeuse ou dothinentérite." DALMAS, Art. *Entérite, Dictionnaire de Médecine*, 2me édit., Paris, 1838, Tome 17, p. 40: "Entérite typhoïde." MARSHALL HALL, *Principles of the Theory and Practice of Medicine*, London, 1837, p. 385: "Glandular eso-enteritis."

‡Thus, for example: Dr. J. F. H. ALBERS—*Erläuterungen zu dem Atlasse der Pathologischen Anatomie*, Bonn, 1847-'57, Abth. IV, S. 171—tells us, in writing of catarrhal inflammation of the intestines: "Es ist mir in einer 25jährigen Praxis keine Leichenöffnung eines an dieser Krankheit Verstorbenen vorgekommen. Dieses in unsern Gegenden so gewöhnliche Leiden wurde regelmässig geheilt."

§This notion appears to have originated with Cullen: "It is with difficulty that I have employed this genus, as it is not very consistent with our plan to let it stand in our nosology. Diarrhœa is universally symptomatic of a great variety of diseases, many of which are different from one another; so that a genus formed from all these is a very complicated one, and comprehends many dissimilar affections and diseases, and there is no use in uniting these under the title of a genus."—The Works of WILLIAM CULLEN, edited by John Thomson, Edinburgh and London, 1827, Vol. II, p. 479. This passage, which forms the first paragraph of the chapter "Of diarrhœa or looseness," in Thomson's edition of Cullen's *First Lines*, does not exist in the editions of that work published during the author's lifetime, but was introduced by Dr. Thomson, with many other passages, from Cullen's manuscript lectures.—See Preface to Vol. I, *op. cit.* Consult, also, the *Dictionnaire des Dictionnaires de Médecine*, Tome III, Paris, 1840, p. 301: "La diarrhée est un symptôme plutôt qu'une maladie proprement dite." WOOD, work cited on page 269, Vol. I, p. 731: "The affection is rather a consequence of certain pathological conditions, than itself a disease." AITKEN, work cited on page 269, Vol. II, p. 675: "This affection is rather a consequence or a symptom of certain pathological states than of itself a disease, and, therefore, it is difficult to give it its true place in nosology."

and inflammation of the intestinal mucous membrane, or of some part of it, but by no means regard these lesions as invariably or even generally present. I cannot assent to this view of the matter, and must regard the diarrhœa which so often occurs in the course of other disorders not as a mere symptom of the primary affection, but as a secondary disease or complication, quite comparable to other intercurrent irritations and inflammations; holding it to depend immediately upon the development of the very same conditions of the intestinal canal as produce it when it exists alone. This subject will be again referred to in connection with tubercular ulceration of the intestines and the diarrhœa of typhoid fever.

DISTINCTION BETWEEN DIARRHŒA AND DYSENTERY.—According to the conception of acute diarrhœa presented above, it is to be distinguished from the milder form of acute dysentery by the absence of tenesmus. The diverse definitions in the books show that various grounds for this distinction have been proposed. These have been both anatomical and clinical: the part of the intestinal canal involved, and the presence or absence of ulceration, belong to the first category; the presence or absence of fever or of contagion, the character of the stools, and the presence or absence of tenesmus, to the latter.*

It would seem, however, that as anatomical considerations are not available during life for the purposes of diagnosis, except so far as clinical phenomena can be shown to correspond to definite lesions, we should give preference to the clinical mode of treating the question. Cullen† distinguished diarrhœa by the fact that it was not contagious and not accompanied by primary fever. At the present day, however, I suppose no one would be willing to affirm either that dysentery is always contagious, or that every case in which there are frequent liquid stools accompanied by fever from the first should be called dysentery; nor does the presence of blood, pus or mucus in the stools seem sufficient to

* From the numerous definitions of the books, I select a few only as samples: SENNERTUS founded his definition partly upon the character of the stools, partly upon the absence of ulceration: "Etsi in genere omne alvi profluvium Diarrhœæ nomine appellari possit; tamen proprie et in specie Diarrhœa is alvi fluxus est, quem immoderata humoris alicujus, præter alimentum crudum et sanguinem, sine exulceratione intestinorum per alvum excretio excitat." SENNERT, *Pract. Med.*, Lib. III, Part. II, Sect. II, Cap. VI, *De Diarrhœa*, Opera, Paris, 1641, Tom. III, p. 115. I note that a recent writer would go even farther than Sennertus, and exclude from the category of diarrhœa all cases in which there was even inflammation of the intestines: "It would seem much better to apply the term diarrhœa to all examples of simple purging; that is to say, to those cases in which the alvine evacuations are frequent, and loose or liquid, without any coexistent inflammation of the intestines."—THOMAS HAWKES TANNER, *The Practice of Medicine*, 5th American, from the 6th London edit., Philadelphia, 1870, p. 665. SAUVAGES based his definition partly upon the character of the stools, partly upon the absence of tenesmus: "Recrementorum et excrementorum utplurimùm fluxiliorum frequens per anum dejectio morbosa, id est, constans et notabilis. Differt à cœliacâ et lienteria ex eo quod non excernantur cibaria, aut cruda, aut in chylum mutata, ut in quibusdam lienteriæ et cœliacæ speciebus, sed excrementitiæ, aut recrementitiæ materies. A tenesmo, quod nisus ad egerendum non sint inanes. Ab hepatirrhœâ et dysenteriâ, quod ejecta non sint cruentata. A melœnâ, quod non sint nigra."—*Nosologia Methodica*, 1763, Tom. III, Pars II, p. 133; *Ib.*, 1768, Tom. II, p. 355. Sauvages and Sennertus distinguished diarrhœa not only from dysentery and the hepatic flux, but from the cœliac flux and lientery. CULLEN, on the other hand, like most modern writers, included the hepatic flux, the cœliac flux, and lientery as species of diarrhœa, and founded his definition upon the absence of contagion and of primary fever: "Dejectio frequens; morbus non contagiosus; pyrexia nulla primaria."—*Apparatus ad Nosologiam Methodicam*, Amsterdam, 1775, p. 216. I may mention HABERSHON, as a comparatively recent author, who has adopted the definition of CULLEN.—*Diseases of the Abdomen*, 2d edit., London, 1862, p. 362. JOHN MASON GOOD'S definition approximates that adopted in the text: "Alvine evacuations crude, loose and too frequent: with little or no griping or tenesmus."—*The Study of Medicine*, Philadelphia, 1825, Vol. V, p. 36. COPELAND'S definition is substantially the same: "Frequent, loose or fluid alvine evacuations without tormina or tenesmus."—*Dict. of Pract. Med.*, London, 1858, Vol. I, p. 522. AITKEN adopts Copeland's very words: "A frequent discharge of loose or fluid alvine evacuations without tormina or tenesmus."—*Science and Practice of Med.*, 3d American, from the 6th London edit., Philadelphia, 1872, Vol. II, p. 675. In view of the frequency of acute griping pains (tormina) in inflammatory cases of acute diarrhœa, I cannot think it advisable to make the absence of this symptom a part of the definition. To the foregoing definitions a few others may be added: "Excrétion alvine, fréquente, copieuse et fluide."—RENAULDIN, Art. *Diarrhée, Dictionnaire des Sciences Médicales*, Paris, 1814, Tome IX, p. 231. "Lorsque les déjections alvines ne sont pas sanguinolentes, c'est une diarrhée. Lorsqu'au contraire les déjections sont sanguinolentes, accompagnées de tranchées et de ténesme, il y a dyssenterie."—TACHERON, work cited on page 268, Tome II, p. 420. "Lorsque les excrétions alvines sont plus fréquentes que de coutume, la matière de ces excrétions plus liquide et plus abondante, qu'il s'y joigne ou non de la fièvre ou des coliques, on dit qu'il y a diarrhée."—DALMAS, Art. *Diarrhée, Dictionnaire de Médecine*, 2d edit., Tome X, Paris, 1835, p. 269. "By diarrhœa is meant frequent liquid, and rather copious, feculent stools; not dependent upon debility of the sphincter ani. In dysentery the stools are not feculent. When a person is weak in the sphincter ani, he may have stools every ten minutes; but he would not, on that account, labor under diarrhœa." JOHN ELLIOTSON, *Principles and Practice of Medicine*, 2d edit., London, 1846, p. 1062. "Lorsque les excrétions alvines sont tout à la fois plus liquides, plus fréquentes et plus abondantes qu'elles ne doivent l'être normalement, que ces matières soient constituées par le résidu des aliments non digérés, ou incomplétement digérés, par le produit des sécrétions intestinales, pancréatique, hépatique, qu'elles renferment ou non du sang ou des débris de membrane muqueuse, on dit qu'il y a diarrhée."—A. TROUSSEAU, *Clinique Médicale de l'Hôtel-Dieu de Paris*, 2me édit., Paris, 1865, Tome III, p. 97. "Those cases are denominated diarrhœa in which the alvine evacuations are more liquid, frequent and copious than in health, without being hemorrhagic or dysenteric in their character."—GEORGE B. WOOD, *Treatise on the Practice of Medicine*, 6th edit., Philadelphia, 1866, Vol. I, p. 731.

† *Loc. cit.*

characterize a case as dysentery if tenesmus be absent. The first may result from hemorrhoids, from tubercular ulceration of the bowels, and several other conditions quite distinct from dysentery; the second from hepatic or other abscesses opening into the intestines; and if the presence of an excess of mucus in the stools be regarded as characteristic of dysentery, we should have to include all the cases usually described under the head of catarrhal or inflammatory diarrhœa. On the whole, therefore, the presence or absence of tenesmus would appear to afford the most convenient means of diagnosis for the acute cases at least; the discrimination of the chronic cases is more difficult, as will be seen hereafter.

Symptoms.—Acute diarrhœa very often occurred as a simple looseness of the bowels, the frequent liquid stools being unaccompanied by noteworthy pain or constitutional disturbance. Slight attacks of this character usually lasted but a few days, and terminated in recovery without requiring medical interference. In other mild cases the painless flux was accompanied by dyspeptic symptoms, such as gastric uneasiness, flatulence and diminished appetite. In severer cases griping pains in the abdomen preceded each stool, and generally received temporary relief from the evacuations; more or less nausea and a feeling of faintness were frequently associated with the pains; occasionally there was vomiting. Still severer cases were accompanied by fever, which generally came on gradually after the diarrhœa was fairly under way, but sometimes began abruptly with a chill at the same time as the flux, or even before the first loose stool. Except when these febrile symptoms expressed the commencement of a malarial or typhoid fever, they usually subsided in the course of a few days, leaving behind a simple looseness which might or might not prove troublesome. Tenderness on pressure upon the abdomen was a common phenomenon in the more severe cases; it varied in degree from the slightest uneasiness to the exquisite sensibility of peritonitis. The cases of diarrhœa in which this symptom coexisted with violent colicky pains and fever were frequently returned on the monthly sick reports under the head of inflammation of the bowels, (enteritis, in the form of reports used at the commencement of the war.) In a sketch of my first impressions with regard to the camp diseases of our army, published in 1863, I adopted the same distinction;* I am now satisfied, however, that it answers no useful purpose, and that the term enteritis, as at present employed in many quarters, serves to divert attention from the extent to which the cæcum and colon are usually involved. It seems preferable, therefore, to describe such cases simply as severe cases of acute diarrhœa, except when the degree of tenderness present indicates the existence of local peritonitis, when they should be spoken of as acute diarrhœa complicated with peritonitis. It will be seen, in a subsequent part of this section, that local peritonitis is a still more frequent complication of dysentery, especially of chronic dysentery, and of tubercular ulceration of the bowels. In the chronic cases particularly, the peritonitis sometimes becomes general, glueing all the viscera into a solid mass without arresting the flux, as is shown by several of the cases recorded in the last section. When peritonitis becomes general in acute cases, however, the bowels usually become constipated, as is the case when general acute peritonitis is the primary disease.

The stools in acute diarrhœa vary in consistency from a soft pasty mass to a watery fluid. At first they are usually feculent, and in mild cases they retain this character

* J. J. Woodward, *Outlines of the Chief Camp Diseases of the United States Armies*, Philadelphia, 1863, p. 218. In my account of the morbid anatomy of acute enteritis, in this work, I fell into the error of supposing the inflammation to affect the small intestine chiefly, though I was obliged to admit that the "colon may be more or less implicated."

throughout, owing their consistency, in part, to a more or less abundant transudation of serum and secretion of modified mucus from the irritated or inflamed mucous membrane, which becomes intermixed with the fæcal mass; in part to a diminution in the absorption of the more fluid portions of the intestinal contents, which normally takes place during their passage through the intestinal canal. In the severer cases the transudation of serum is sometimes so copious that the stools are correctly described as watery; or the secretion of modified mucus may be so abundant that it can be detected by the naked eye as a glairy admixture. Still further modifications in the character of the stools are produced by changes in the quantity of biliary coloring matter contained in the stools, its deficiency rendering them pale or clay colored, while its increase makes them yellow, greenish or tar-like. The predominance of one or another of these ingredients gives the character to the stools in each individual case, and the variations resulting have served, in part at least, as the basis of the subdivision of diarrhœa into varieties in which systematic writers formerly indulged so liberally.*

* Besides the character of the stools, the presence or absence of fever, the causes determining the flux, or the conditions with which it is associated, have served as an excuse for distinguishing varieties, which, hence, became very numerous in the writings of the Arabian physicians, their disciples, and certain subsequent European physicians, especially the Nosologists. The Greek and Roman physicians made use of a comparatively simple classification. In the Hippocratic writings all the various forms of alvine flux are included under the designations diarrhœa, lientery, dysentery and tenesmus. The term diarrhœa (*διάῤῥοια*) is nowhere formally defined, but is frequently used, and always in the modern sense, except that those chronic fluxes (whether commencing as diarrhœa or dysentery) in which undigested food is recognised in the stools are spoken of as lientery. Variations in the characters of the stools were expressed by the use of adjectives. Thus, HIPPOCRATES speaks of bilious and watery diarrhœas (*διάῤῥοιαι χολώδεες καὶ ὑδατώδεες*) as occurring during the Summer and Autumn in the island of Thasus—*Epidem.* Lib. I, Sect. 2, [Ed. Littré, T. II, p. 617.] So also diarrhœa of long continuance was designated by appending an adjective, HIPPOCRATES speaks of long-lasting diarrhœa (*διάῤῥοια μακρή—Aphorisms* VI, 15) [Ed. Littré, T. IV, p. 567]—and *διάῤῥοια πολυχρόνιος—Prognostics*, § 8 [Ed. Littré, T. II, p. 131]—which is the equivalent of our modern (barbarous) term chronic diarrhœa. In the spurious treatise *On affections*, § 25 and 27, [Ed. Littré, T. VI, pp. 237–8,] there is a summary account of diarrhœa, especially of the chronic form, and an explanation of the mode in which it may be generated by a flux of phlegm from the head and chest to the belly. This doctrine will be again referred to in the notes to the part of this section which refers to dysentery. The ancient opinions with regard to dysentery, tenesmus and lientery will also be discussed in subsequent notes. The Greek writers who followed HIPPOCRATES continued to use these terms in the sense in which they occur in the Hippocratic writings, except that they separated also the cœliac affection as well as lientery from the chronic fluxes. (See a note on the subject of the cœliac affection in the part of this section which treats of chronic dysentery.) I note in the treatise *Definitiones Medicæ* (which has been attributed to GALEN, but without sufficient evidence) the following definition: "Diarrhœa copiosior fluxio est alvi diuturna sine phlegmone et ulceratione," which I should have included in the note to page 271 *supra—Opera Galeni*, Ed. Kühn. T. XIX, p. 421. For the views of the Greek physicians on the subject of diarrhœa consult especially, besides the numerous allusions scattered through the writings of HIPPOCRATES and GALEN, the summary, drawn chiefly from PHILUMENUS and GALEN, in the compilation of ÆTIUS—Tetrab. III, Cap. 35 and 36—and the chapter *περὶ ῥευματισμοῦ τῆς γαστρός* in the writings of ALEXANDER of TRALLES—Lib. VIII, Cap. 7. (This chapter, professedly borrowed from PHILUMENUS, is almost identical with Cap. 35, Tetrab. III of ÆTIUS, which is derived from the same source.) CELSUS used the designation *Fluor rentris* as a generic term, including lientery, (laevitas intestinorum,) dysentery, (tormina,) and tenesmus as well as diarrhœa.—Lib. IV, Cap. 16, [Lee's ed., London, 1831, Vol. I, p. 299.] The term *alvi fluxus*, so much used in the same sense by subsequent Latin writers, does not occur in his works. He uses, however, the expression *fluens alvus* to indicate diarrhœa—Lib. II, Cap. 6, [*op. cit.*, p. 69;] so also he says: "*Alvus si vehementius fluit*, hominem infirmat"—Lib. II, Cap. 12 [*op. cit.*, p. 108]—in speaking of hypercatharsis. Among the other expressions used in the writings of CELSUS to indicate diarrhœa, I note *cita alvus*—Lib. I, Cap. 6 [ed. cited, Vol. I, p. 45] and Lib. II, Cap. 8, [*op. cit.*, Vol. I, p. 88,] and *dejectio*—Lib. IV, Cap. 19, [*op. cit.*, p. 302.] This latter term he uses also to express the action of purgative medicines—Lib. II, Cap. 12, [*op. cit.*, p. 108.] The Arabian physicians treated of diarrhœa and the various other fluxes at great length, and while borrowing after their fashion from the Greeks, especially from GALEN, showed their usual tendency to elaborate classification and the multiplication of subdivisions. Thus, in the *Canon* of AVICENNA—Lib. III. Fen. 16, Tract. 1 and 2 [Juntas ed., Venice, 1595, T. I, p. 809 *et seq.*]—the various forms of flux are classified in accordance with their supposed causes. Either they result from dietetic errors, or from some lesion of the head, the liver, the spleen, the mesentery, the stomach, the intestines, or of the whole body. After a detailed discussion of the varieties of flux resulting from these causes, separate chapters are given [in Tract. 2] on the treatment of lientery, [flux from the stomach, either with or without ulceration, Cap. 2 and 3,] the hepatic flux, [Cap. 1,] cholera morbus, [Cap. 4,] the splenetic flux, [from black bile, fluxus melancholicus, Cap. 5,] flux of blood without ulceration of the intestines, [Cap. 6: see a subsequent note with regard to the opinions of the Greek physicians on this subject,] flux from excoriation or ulceration of the intestines, [Cap. 7, ulcerative dysentery,] tenesmus, [Cap. 16,] and of seven varieties of simple diarrhœa, viz: (a) diarrhœa from errors of diet, [fluxus ventris factus propter cibos, Cap. 8.] (b) catarrhal or mucous diarrhœa, [fluxus ex capite, fluxus cerebralis, Cap. 9,] (c) diarrhœa from obstruction of the liver, [fluxus oppilativus, Cap. 10,] (d) colliquative diarrhœa, as in hectic and phthisis, [Cap. 11,] (e) diarrhœa from suppressed perspiration, [fluxus factus a spissitudine cutis, Cap. 12.] (f) diarrhœa from the use of purgatives, [fluxus medicinalis, Cap. 14,] and (g) critical diarrhœa, [fluxus creticus, Cap. 15.] The European disciples of the Arabian physicians imitated this elaborate classification. Thus, in the *Lilium Medicinæ* of BERNARD de GORDON, besides chapters on lientery, dysentery, tenesmus and the hepatic flux, [Partic. V, Cap. 13, 14 and 15, and Partic. VI, Cap. 4, Venice ed. of 1496, fol. 159 *et seq.*,] we find separate headings for fluxus ventris propter catarrhum or fluxus cerebralis; fluxus ventris propter oppilationes epatis; fluxus splenecticus; fluxus ex colirica passione; fluxus liquefactivus; fluxus propter pororum clausionem; fluxus propter pororum cutis apertionem; fluxus propter medicinas laxativas; diarria (diarrhœa, that is, as he explains, a simple humoral flux;) fluxus ventris propter cibaria; fluxus ventris propter aerem; fluxus ventris in balbutientibus et traulis, [stammerers and lispers;] fluxus ventris propter dispositiones naturales; and fluxus ventris propter totum corpus. [See the latter part of Cap. 14 and 16, Partic. V.] These subdivisions reappear with but few modifications in the writings of SENNERTUS, who, besides separate chapters on dysentery, sanguineous and hepatic flux, tenesmus and cholera, (cholera morbus,) has one on alvine fluxes in general (de alvi fluxibus in genere) and one on diarrhœa. In the chapter on alvine fluxes in general he gives a brief and clear exposition of the varieties of these fluxes, basing their subdivision into species on the characters of the matters excreted, the sources whence these matters proceed, and the several efficient causes which in different cases produce the disease, after which he treats at length of lientery and the cœliac affection. In the chapter on diarrhœa he treats of the varieties of that form of flux under the following heads: 1, de fluxu chyloso; 2, de diarrhœa à toto corpore cum febre; 3, de fluxu colliquativo; 4, de diarrhœa à toto corpore sine febre; 5, de diarrhœa à ventriculo et cibis corruptis; 6, de diarrhœa à vermibus; 7, de diarrhœa ab epate, ac bilioso humore; 8, de diarrhœa à liene et humore melancholico; 9, de diarrhœa ab utero; 10, de diarrhœa à cerebro; 11, de diarrhœa, quæ accidit infantibus, dum dentes erumpunt; 12, de diarrhœa ab hypercatharsi et veneno sumpto.—SENNERT,

Such distinctions as feculent diarrhœa, serous diarrhœa, mucous diarrhœa and bilious diarrhœa are still in common use, and correctly describe the varying character of the discharges. The use of these terms cannot be objected to, but it should be remembered that the stools are often successively feculent, bilious, serous and mucous during the same case, so that it seems hardly worth while to attempt to establish formal varieties of the disease on this basis, though an examination of the stools is important as an aid in determining the actual condition of the patient at the time of the examination.

Besides the variations in the consistency and quantity of the stools, they vary considerably in *color*, as already hinted. This is dependent, in part, upon the amount of biliary matter they contain and the degree of decomposition to which it has been subjected; in part upon the presence of blood, which can often be recognized by the microscope when its existence would not otherwise be suspected; and in part upon the introduction, along with the ingesta, of certain articles of food and medicine. Among articles of diet, spinach, coffee and porter have been mentioned by Osborne as furnishing coloring matters which resist the action of the digestive organs and impart their own color to the stools.* Among medicines, the preparations of iron† make the stools greenish-black or black, subnitrate or subcarbonate of bismuth brownish-black, sulphate of copper makes them dark green, while calomel gives rise to a green, greenish-brown, or yellowish-brown color, which has long attracted the attention of practitioners, and has exercised a powerful influence on the use of mercurials in the treatment of disease, because it has been attributed to an increased secretion of bile, but which is in reality due, in part at least, as has been shown by Lehmann, to the formation of sulphide of mercury by the action of the sulphuretted hydrogen contained

---

Pract. Med., Lib. III, Part. II, Sect. II, Cap. VI, De Diarrhœa. [*Loc. cit.*, p. 271 *supra.*] In the *Nosology* of SAUVAGES the order alvi fluxus is subdivided into twelve genera, viz: hepatirrhœa, hæmorrhois, dysenteria, melæna, nausea, vomitus, ileus, cholera, diarrhœa, cœliaca, lienteria and tenesmus. Of the genus diarrhœa he made twenty-one species, viz: 1, d. stercorosa; 2, d. vulgaris; 3, d. febrilis; 4, d. pituitosa; 5, d. carnosa; 6, d. variolosa; 7, d. acrasia; 8, d. biliosa; 9, d. arthritica; 10, d. serosa; 11, d. purulenta; 12, d. Chiliensis; 13, d. colliquativa; 14, d. verminosa; 15, d. à dentitione; 16, d. ab hypercatharsi; 17, d. choleriodes; 18, d. adiposa; 19, d. lactentium; 20, d. febricosa; 21. d. pleuriticorum. As the genera hepatirrhœa, cœliaca and lienteria of SAUVAGES were united with the genus diarrhœa by CULLEN, I subjoin their species: *Hepatirrhœa:* 1, h. vera; 2, h. intestinalis; 3, h. à vulnere; 4, h. mesenterica; 5, h. scorbutica; 6, h. cruenta; 7, h. intermittens. *Cœliaca:* c. chylosa; c. purulenta; c. mucosa; c. lactea. *Lienteria:* l. ex ulcere ventriculi; l. spontanea; l. scorbutica; l. aphthosa; l. secundaria.—*Nosologia Methodica*, Amsterdam, 1768, Tom. II, pp. 321 *et seq.* CULLEN, in the earlier editions of his Nosology, adopted, under the head of diarrhœa, most of the above species of Sauvages, dividing the series into idiopathic and symptomatic, and making in all fifteen of the former and twenty-four of the latter.—*Apparatus ad Nosologiam Methodicam*, Amsterdam, 1775, p. 216. Subsequently, however, he reduced the number of idiopathic species to six, as follows: *Idiopathic species*—1, d. crapulosa; 2, d. biliosa; 3, d. mucosa; 4, d. cœliaca; 5, d. lienteria; 6, d. hepatirrhœa; *Symptomatic species*—d. febrilis; d. febricosa; hepatirrhœa intermittens; diarrhœa variolosa; d. pleuriticorum; d. arthritica; d. colliquativa; d. choleriodes; hepatirrhœa vera; h. a vulnere; h. mesenterica; dysenteria a mesenterii vomica; diarrhœa purulenta; cœliaca purulenta; hepatirrhœa scorbutica; dysenteria scorbutica; lienteria scorbutica; l. ex ulcere ventriculi; l. aphthosa; l. secundaria; diarrhœa verminosa; d. a dentitione; d. Chiliensis; d. acrasia.—*Nosologia Methodica*, edited by JOHN THOMSON, Edinburgh, 1820, p. 114; also works by JOHN THOMSON, Edinburgh, 1827, Vol. I, p. 312. JOHN MASON GOOD reduces the list of species to eight, viz: 1, d. fusa; 2, d. biliosa; 3, d. mucosa; 4, d. chylosa; 5, d. lienteria; 6, d. serosa; 7, d. tubularis; 8, d. gypsata.—*The Study of Medicine*, Philadelphia, 1825, Vol. I, p. 153. Most modern writers are disposed to reduce the number of species very much; the tendency to make minute subdivisions still exists, however, in certain quarters. Thus, TROUSSEAU makes seven species: "J'admets donc sept espèces de diarrhées; l'une est la diarrhée catarrhale ou phlegmasique; la seconde est la diarrhée sudorale (je vous expliquerai plus loin ce que j'entends par là;) la troisième reconnâit pour cause une sécrétion exagérée de l'intestin se produisant sous l'influence de certains troubles de l'innervation; la quatrième est encore une diarrhée catarrhale, mais ici le catarrhe n'est survenu que consécutivement à un flux intestinal excessif; la cinquième espèce, je l'appelle diarrhée par excès de tonicité de l'intestin; la sixième dépend d'un vice dans l'alimentation, des mauvaises qualités des ingesta, mauvaises qualités qui peuvent être absolues ou relatives; la septième, enfin, se rattache à l'existence de maladies organiques."—*Clinique Médicale de l'Hotel-Dieu*, 2me édit., Paris, 1865, Tome III, p. 97; and HABERSHON describes six, viz: diarrhœa crapulosa, bilious diarrhœa, catarrhal or mucous diarrhœa, dysenteric diarrhœa. choleraic diarrhœa and melæna.—*Diseases of the Abdomen*, 2d edit., London, 1862, p. 362.

* JONATHAN OSBORNE, *On some Leading Facts to be recollected in the Examination of the Fæces in Disease.*—The Dublin Quarterly Journal of Medical Science, Vol. XV, 1853, p. 104.

† In connection with the action of iron, the effect of certain chalybeate waters in coloring the stools may be mentioned. Thus, CARL KERSTEN—*Ueber die Ursache der grünen Färbung der Stuhlentleerungen bei dem Gebrauche der Marienbader Mineralwässer*, Journal der Chir. u. Augenheilk. von v. Walther und v. Ammon, Bd. III, [Berlin, 1844,] Heft 2, S. 153—showed that the green color of the evacuations observed after a course of Marienbad waters, long supposed to be due to the evacuations of bile, was really due to the formation of the sulphuret of iron. These investigations were criticised by FRANKL—*Bemerkungen über die Ursache der grünen Färbung der Stuhlentleerungen bei dem Gebrauche der Marienbader Mineralwässer*, Heller's Archiv, Jahrgang 1845, Wien, S. 105—but BERZELIUS confirmed KERSTEN'S views, and extended them to the case of all chalybeate waters, remarking that every chalybeate water, whether it contains sulphates or not, produces a similar appearance in the evacuations. See an extract from a letter from BERZELIUS to KERSTEN, in v. Walther's u. v. Ammon's Journal. Bd. IV, [1845,] Heft 1, S. 161. According to WM. LAMBL—*Mikroskopische Untersuchungen der Darm-Excrete*, Prager Vierteljahrschrift, 1859, Bd. I, S. 53—sulphate of copper given medicinally also bestows a characteristic color upon the stools, which become dark-green; the intensity of the color varying with the quantity of bile-pigment present. The effect may be imitated by adding sulphate of copper in solution to the stools.

in the intestinal canal.* This statement is supported by the carefully made observations of several other chemists, whose accordant testimony leaves no reasonable doubt with regard to the matter, notwithstanding the negative results of Simon. Lehmann, however, has declared that he was convinced, by his own analyses, of the occasional presence of an excess of almost unchanged bile in calomel stools, a circumstance which is by no means surprising, since it also occurs occasionally after the action of other purgatives, and in the course of diarrhœas in which no purgatives have been administered; moreover, Bamberger has pointed out† that the presence of an increased quantity of biliary matters in the stools is no certain indication of increased secretion of bile, since it may result from a diminution of the decomposition and reabsorption of the bile normally taking place in the intestinal canal, which is to be anticipated in view of the more rapid movement of the intestinal contents and the morbid condition of the absorbing surface.

A correct interpretation of the action of calomel on the quantity of the biliary secretion has special significance in connection with the question of its administration, as in many cases of diarrhœa and dysentery, in conditions characterized by a deficiency of biliary matters in the stools. Now, experiments on dogs would appear to show that, so far from calomel increasing the secretion of bile, it actually diminishes it. Such experiments had been published by Nasse,‡ Kölliker,§ Mosler,‖ and Scott,¶ but did not attract very much attention before the report to the British Medical Association in 1868, of the committee of which Bennett

---

* C. G. LEHMANN—*Physiological Chemistry;* translated by George E. Day, London; printed for the Cavendish Society, 1853, Vol. II, p. 145:—"My own investigations lead to the following conclusions: After calomel has been taken, we always find mercury in the stools, whether they be green, or black, or of their ordinary color; this had previously been distinctly established by Hermann, (*De Rationibus Dosium Calomellis, &c.*, Diss. Inaug. Hannuiæ, 1839,) and even more strongly by Merklein, (*Ueber die grünen Stühle nach dem Gebrauche des Calomels im Typhösen Fieber*, Inauguralabhandlung, München, 1842.) Höfle has likewise convinced himself of the presence of mercury in the fæces in these cases. The sulphide of mercury may be separated, by rinsing, from the evacuation, when stirred in water, as Merklein was the first to observe, and its chemical nature may be then very easily recognized; the dark color of the sulphide of mercury, when finely comminuted, may certainly, like sulphide of iron, give rise to a light-green color with animal substances, and especially with the yellow bile-pigment; indeed, powdered calomel, when triturated with yellowish-brown excrements, causes them, according to Hermann, to assume a greenish color. But, notwithstanding these facts, we should not deny the presence of almost unchanged bile in calomel stools, for we may with facility recognize the presence of bile-pigment by nitric acid, and of the resinous biliary acids, by Pettenkofer's test, in the alcoholic extract when carefully prepared; and this extract may usually be obtained in considerable quantity. Every one who himself analyses such stools is, at all events, led to the subjective conviction that a part of the green and light color may be dependent on bile-pigment." On the other hand, SIMON—*Animal Chemistry*, translated by G. E. Day, London, 1846, Vol. II, p. 387—tells us: "Various attempts that I made (by Smithson's method) to detect mercury in calomel-stools proved unsuccessful;" and GOLDING BIRD—*On the nature of the green alvine evacuations of children*, The London Medical Gazette, Vol. I, N. S., 1845, p. 801—examined one green stool passed "by a hydrocephalic infant whilst under the influence of mercury," and arrived at the conclusion that the green color was due to the presence of altered blood, and that "the green stools alluded to are but a form of melœna." H. C. WOOD, Jr.—*A Treatise on Therapeutics*, Philadelphia, 1874, p. 384, also 2d ed., 1876, p. 434—refers to these negative observations of SIMON and GOLDING BIRD as proof that mercury does not exist in the green stools, but does not mention the positive testimony of HERMANN, MERKLEIN, HÖFLE and LEHMANN to the fact that it always does. The opinion of LEHMANN, just quoted, that unchanged bile may exist also in the calomel stools, is supported by the earlier testimony of MICHÉA—*Le calomel exerce-t-il une influence spéciale sur la sécrétion biliaire?* L'Union Médicale, 1848, No. 125, p. 495, and No. 126, p. 500—who tested the stools by mixing them with twice their volume of distilled water, filtering, and adding nitric acid. No quantitative procedure was attempted by him. The stools of six healthy persons being treated in this way no color was produced. Those of three cases of gastro-intestinal affections were examined in the same way; in only one of them was much bile indicated by the nitric-acid test. Calomel was given to eight persons in doses varying from six decigrammes to a gramme. In but four of these cases did green stools result from its action. In two of these four cases the characteristic play of colors was produced by nitric acid, though the green was not as beautiful as usual in the reaction with bile. In the other two no green was produced, but a reddish-yellow, (un jaune fauve,) and it was almost without any subsequent transformations. Nevertheless, MICHÉA concluded that bile was present in these as well as the other two cases, because in all four the precipitate produced by nitric acid showed the presence of albumen, which he appears to have thought must be derived from the bile. Finally, the stools of five persons who had taken neutral salts, or resinous purgatives, gave no reaction with nitric acid. The crude character of the chemistry of these experiments renders criticism at the present time quite unnecessary. They prove nothing, and yet they continue to be appealed to by those who wish to believe that calomel is a cholagogue.

† Page 218 of Work, cited on page 266.

‡ H. NASSE—*Commentatio de bilis quotidie a cane secreta copia et indole*, Marburgi, 1851, quoted in SCHMIDT'S *Jahrbücher*, Bd. 73, [1852,] S. 274-'77, and CANSTATT'S *Jahresbericht*, 1852, Bd. I, S, 156—arrived at the conclusion, from experiments on dogs with biliary fistulæ, that although calomel increases the absolute quantity of bile, it diminishes its solid ingredients. Fever and diarrhœa, he found, diminished the quantity secreted.

§ A. KÖLLIKER and H. MÜLLER—*Bericht über die während der Sommersemester* 1853 *und* 1854 *in der physiologischen Anstalt der Universität Würzburg angestellten Versuche*, Würzburg Verhandlungen, Bd. V, 1855, S. 213—administered four grains of calomel to a dog with biliary fistula, and observed at first a slight increase, but next day a slight diminution, in the amount of bile. On repeating the dose of calomel a second and third time the quantity of bile diminished without any previous increase.

‖ FRIEDRICH MOSLER—*Untersuchungen über den Uebergang von Stoffen aus dem Blute in die Galle*, Virchow's Archiv, Bd. XIII, 1858, S. 41—administered calomel to two dogs with biliary fistulæ, and arrived at the conclusion that this drug neither passes so speedily into the bile, nor produces so marked an increase in the quantity of that fluid, as we are inclined to assume in practical medicine.

¶ GEORGE SCOTT—*On the Influence of Mercurial Preparations upon the Secretion of Bile*, Beale's Archives of Medicine, Vol. I, 1859, p. 209—gave calomel in large doses four times, with intervals of a few days, to a dog with biliary fistula, and found in every case "a diminution in the amount of fluid bile and bile-solids secreted."

was chairman.* The elaborate character of the researches upon which that report was based, and the high character of the reporter, gave it great weight, and, notwithstanding the objections made in various quarters, its conclusions have been widely adopted. More recently Röhrig experimented on wourarized dogs with large doses (20 grains) of calomel, and obtained contrary results,† the secretion of bile appearing actually to increase after

* *Report of the Edinburgh Committee on the action of Mercury, Podophylline and Taraxacum, on the biliary secretion;* by JOHN HUGHES BENNETT, Part I, The British Medical Journal, Vol. II for 1868, p. 78; Part II, *ib.*, Vol. I for 1869, p. 411. In these researches the committee operated on forty-one dogs for the establishment of biliary fistulæ, and succeeded in obtaining nine animals with well-established fistulæ. A series of experiments on one of these dogs with blue-pill, and on four of them with calomel, led to the conclusion that both blue-pill and calomel, in purgative doses, diminish the biliary secretion, and that in doses too small to purge they do not increase it. The committee also show by experiment that the action of mercury upon the salivary glands, mouth, intestine, appetite and general nutrition of the dog is the same as its action on man, except that proportionately larger doses are required to produce a given effect, and they hence infer that its action on the liver is the same in both. Experiments on three of the dogs with corrosive sublimate led to the conclusion that this preparation also does not, in small doses, increase the biliary secretion, and diminishes it if given in doses sufficient to produce purgation, or if its action is kept up long enough to impair the general health. Experiments with podophylline showed that in small doses it diminished the solid constituents of the bile, and in purgative doses, both the fluid and the solid. Taraxacum, in doses of from sixty to two hundred and forty grains, affected neither the biliary secretion, the bowels nor the general health of the animals to which it was given. Several of the dogs suffered from spontaneous diarrhœa, and one of them from dysentery, while under observation. In all these cases a diminution in the quantity of the bile was observed. It has been objected to these experiments that being made on dogs the results do not apply to man. See the remarks of the President of the British Association, (Dr. ACLAND,) at the Oxford meeting.—The British Medical Journal, Vol. II for 1868, p. 176; see also A. W. BARCLAY, *Action of Mercury on the Liver*, *ib.*, Vol. I for 1871, p. 49. Moreover, four members of the Edinburgh committee, R. CHRISTISON, D. MACLAGAN, T. R. FRASER, and ARTHUR GAMGEE, have published letters—*ib.*, Vol. I for 1869, p. 482—in which they express the opinion that the reporter has drawn conclusions not fully warranted by the experiments. (See Dr. Bennett's reply to these letters, *ib.*, p. 593.) These gentlemen, however, do not impugn the accuracy of the experiments themselves; indeed, both Fraser and Gamgee took a prominent part in their performance. Numerous articles in favor of the views of the committee, and opposed to them, have since appeared in the Medical Journals, but none, which have met my eye, are based upon experimental observations except those of Röhrig and Rutherford, mentioned below. One of the most interesting and ingenious of these articles is that by THOMAS R. FRASER—*Sketch of the present state of our knowledge respecting the action of mercury on the liver*, Edinburgh Med. Jour., Vol. XVI, 1871, p. 904, which contains the best presentation of the argument in favor of the old doctrine of the cholagogue action of mercury with which I am acquainted, with copious references to the literature. It may serve to indicate how little proof there is of the truth of the old view to mention the remark of this writer, that the observations of MICHÉA, cited above, constitute "the most satisfactory and convincing evidence on the subject." I confess to some surprise at finding my friend H. C. WOOD, Jr., (*op. cit., supra*, on p. 275,) among those who refuse to be convinced by experiments on dogs. This writer, in spite of the earnestness with which he combats the objection, "that drugs do not act upon the lower creatures in the same manner as they do upon man," (*op. cit.*, preface to first ed., p. 7 *et seq.*,) when he comes to discuss the calomel question, remarks that "The canine diet and digestion are so different from the human, that it is to be expected that medicines acting upon the digestive apparatus will influence dogs differently from man." Hence he concludes that experimental evidence must be "all laid aside when we desire to study the question as to the cholagogue action of remedies upon man, and that our conclusions must be based solely upon clinical evidence," (*op. cit.*, 1st ed., p. 374; 2d ed., p. 423.) Like FRASER, from whose article he appears to borrow largely, he regards the observations of MICHÉA as "the most satisfactory evidence" in favor of the cholagogue action of mercury; but apparently, from not consulting the original paper, he mistakes the results arrived at by that inquirer, making them appear very much more "satisfactory" than they really were, remarking: "Calomel having been given to eight healthy persons, five men and three women, bile was readily demonstrated in the green passages produced in all of the subjects," (*op. cit.*, 1st ed., p. 384; 2d ed., p. 435,) whereas MICHÉA himself only claimed this result in four of the eight cases. Even experiments on dogs are less uncertain than this kind of "clinical evidence." CHARLES MURCHISON—*Croonian lectures on functional derangements of the Liver*, Lancet, May, 1874, p. 611—has recently suggested that "the difference of opinion between the physiologist and the practical physician" on this subject may be reconciled by considering that "a large part of the bile secreted by the liver and thrown into the bowel is constantly being reabsorbed, to reach the liver again; and accordingly, when the common bile-duct is tied, and a fistulous opening into the gall-bladder established, the quantity of bile which escapes from the fistulous opening immediately after the operation is much greater than at any time subsequently, (SCHIFF.) Mercury and allied purgatives produce bilious stools by irritating the upper part of the bowel, and sweeping on the bile before there is time for its reabsorption." In this way he thinks mercury relieves "a loaded liver far more effectually than if it acted merely by stimulating the liver to increased secretion, as was formerly believed, and as some authorities still maintain; for in this case it might be expected to increase, instead of diminish, hepatic congestion." This suggestion has been still further elaborated by T. LAUDER BRUNTON—*On the action of purgative medicines*, The Practitioner, June, 1874, p. 403—who also holds, on the basis of the experiments of SCHIFF, that a portion of the bile poured into the intestinal canal is reabsorbed and again excreted, so that—"In the normal state of the animal the liver is always doing two things: it is *forming* new bile, and it is *excreting* old bile which it has received from the intestine by means of the portal vessels," p. 411. "If the peristaltic action of the whole intestinal canal is quickened by a purgative, the bile will be hurried rapidly onwards and evacuated before there has been time for its reabsorption, and the liver being thus relieved will be able to excrete any bile still remaining in the blood," p. 413. SCHIFF—*Gallenbildung, abhängig von der Aufsaugung der Gallenstoffe*, Pflüger's Archiv, 3te Jahrgang, 1870, S. 598—found, in the experiments on which the view advocated by MURCHISON and BRUNTON depends, not only that the quantity of bile which escapes from a biliary fistula is much greater immediately after the operation than it subsequently becomes if none is allowed to enter the intestinal canal, but also that if the animal has at the same time a duodenal fistula, and the bile escaping from the biliary fistula is injected into the duodenum, the quantity which escapes speedily increases to a degree proportional to the quantity thus injected. Ox-gall injected into the duodenum produces the same effect. These results may be verified by means of what SCHIFF calls an "amphibolen gallenfisteln;" that is, a simple biliary fistula made with a wide canula (1.3 to 1.5 centimetres in diameter) and without ligation of the common duct. If the canula is corked, the bile follows its normal course; if the cork is taken out, the bile all escapes externally, the pressure not being sufficient for any of it to enter the intestine. In such dogs the quantity of bile which escapes externally during ten minutes' observation, if the fistula had previously been kept closed for some hours, is nearly three times as great as if it had been left open.

† A. RÖHRIG.—*Experimentelle Untersuchungen über die Physiologie der Gallenabsonderung*—STRICKER'S Jahrbücher, 1873, Heft II, S. 254. I am not satisfied of the value of these researches. The animals were paralyzed by wourara, and artificial respiration kept up by means of a tube inserted into the trachea. Instead of making a biliary fistula the abdominal cavity was opened, a tube inserted into the biliary duct, and the rapidity of the secretion estimated by the frequency of the drops as measured by the beats of a metronome. The following is a translation of the passage which refers to the action of calomel: "Large doses of calomel (twenty grains for a dog) seldom succeeded in renewing the flow of bile if it had entirely ceased, although the drug named is capable of improving the merely slackened production of bile in a certain manner. As is well known, calomel has for a long time played a great role as a means of promoting the secretion of bile; on the other hand, Scott (Arch. of Med., Vol. I, p. 209) has denied this opinion, and thought himself able to afford experimental proof that it would diminish the bile secreted in a unit of time. I certainly saw, in two corresponding cases, that the secretion of bile which had completely ceased was, by the introduction into the intestine of an emulsion of twenty grains of calomel, again reproduced after about two hours in such a way that a drop flowed every 120–130 beats of the pendulum. An hour later the secretion flowed at the rate of a drop to 85 beats in one case, a drop to 79 in the other; a speed which again diminished after thirty minutes, and entirely ceased after thirty-five

the use of the drug; he referred in his paper to the investigations of Scott, but did not mention those of the Edinburgh committee, and his experiments were not made under conditions which can be regarded as very satisfactory. The latest investigations into this matter with which I am acquainted are those of Rutherford and Vignal,* which were undertaken with full knowledge of the labors of their predecessors, and with every known precaution to secure accuracy. These experiments afford substantial support to the conclusions of the Edinburgh committee, so that while it may be admitted that further investigation is desirable, it must be conceded that the weight of the experimental evidence thus far accumulated is against the opinion that the secretion of bile is increased by calomel.

Besides the foregoing ingredients, *fragments of undigested food* frequently make their appearance in the stools. Bits of hard bread, scraps of undigested meat, the husks of peas and beans, the seeds of fruits, and many similar articles, can often be detected with the naked eye; and even when this is impossible, microscopical examination almost invariably detects the debris† of the food in still larger quantities than are ordinarily present in healthy

more. On the other hand, when the mere acceleration of a still existing secretion was concerned, calomel showed itself more certain, and afforded very nearly the same results as I have already fully detailed for the sulphate of magnesia." In the experiment with sulphate of magnesia here referred to, fifty cubic centimetres of a saturated solution of sulphate of magnesia were injected into the intestines of a dog whose secretion had diminished to a drop every 96–98 beats; the flow increased in frequency to one drop every 34 beats in an hour and a half, after which it again diminished, and ceased entirely four hours after the commencement of the experiment. The fact that these experiments were made upon animals with their abdominal cavities laid open, and that they hence necessarily continued so short a time after the administration of the drug, must materially shake our confidence in the value of the results. If they prove anything at all as to calomel, they show only that it is almost as active a cholagogue as Epsom salt.

* WM. RUTHERFORD and M. VIGNAL—*Experiments on the biliary secretion of the Dog*, Jour. of Anat. and Physiology, Vol. X, [1876,] p. 253, and Vol. XI, p. 61—point out that the experiments of RÖHRIG were performed upon fasting animals, while the Edinburgh committee used animals which were not fasting. Their method of investigation was a modification of that of RÖHRIG. Dogs which had fasted eighteen hours were curarized and artificial respiration set up. The abdomen was then opened, a glass cannula was tied in the common bile-duct, the cystic duct was clamped, and the bile which flowed through the canula was carefully collected and measured every fifteen minutes, instead of counting drops, the size of which would vary with the varying viscidity of the bile. The medicines experimented with were injected directly into the duodenum. After the canula was inserted the wound in the abdomen was closed, and the animal covered with cotton-wool to enable it to regain its normal temperature. They also analyzed the bile in many cases, and made post mortem examinations of the condition of the alimentary canal. Four dogs were thus experimented on with calomel. In three instances, two doses of ten grains of calomel each were given an hour or more apart; in the fourth, four doses of three grains each were given. In all four cases the calomel had a purgative effect. In one of the cases in which two ten-grain doses were given the quantity of bile excreted was increased: it was 3.35 cubic centimetres during two hours before the administration of the calomel, 4.25 cubic centimetres during the two hours following the first dose, and 4.72 cubic centimetres during the two hours following the second. In the other three cases the quantity of bile was positively diminished. In the case in which four three-grain doses were given, the bile was analyzed before and after the action of calomel, with the following results:

	BEFORE IT WAS GIVEN.	AFTER THE THIRD DOSE.
Water	86.00	87.78
Bile-acids, pigments, cholesterine, fat	8.40	7.85
Mucus	4.57	3.40
Ash	1.03	0.97
	100.00	100.00
Velocity of secretion per half hour	0.78 c. c.	0.4 c. c.

From this it is seen that the bile was not only rendered more scanty, but more watery, by the action of calomel. With regard to the single case in which the quantity of bile appeared to be increased, the authors ask: "In consideration of the negative results as regards the cholagogue action of calomel in Exps. 31, 32 and 33, is it not possible that the increase in the biliary secretion observed in Exp. 30 might have taken place during the course of the experiment had no calomel been given?" The authors experimented with a number of substances, some of which, as for example podophylline and ipecacuanha, produced a marked increase of the biliary secretion. The same effect was also produced by the inhalation of chloroform, (*op. cit.*, Vol. XI, p. 62.) It may be added that RUTHERFORD was a junior member of BENNETT's committee, and, in connection with GAMGEE, performed the experiments which formed the basis of its report, so that he has had considerable experience in matters of this kind.

† On the presence of such debris in healthy fæces and on the composition of the healthy fæces generally, consult BERZELIUS—*Analyse de la Matière Excrémentitielle de l'Homme*, Annales de Chimie, Tome LXI, (1807,) p. 314; WEISARG—*Mikroskopische und Chemische Untersuchungen der Fæces gesunder, erwachsener Menschen*, Giessen, 1853; I have not been able to see this thesis, an abstract of which is given in the British and Foreign Medico-chirurgical Review, Vol. XIV, 1854, p. 528; J. F. SIMON—*Animal Chemistry;* translated by George E. Day, London, 1846, Vol. II, p. 366; LEHMANN—*Physiological Chemistry;* translated by George E. Day, London, 1853, Vol. II, p. 141; W. MARCET—*An Account of the Organic Chemical Constituents or Immediate Principles of the Excrements of Man and Animals in the Healthy State*, Philosophical Transactions, Vol. CXLIV, 1854, p. 265; also the same, *On the Immediate Principles of Human Excrements in the Healthy State*, Ib., 1857, Vol. CXLVII, Part I, p. 403; and AUSTIN FLINT, jr.,—*The Physiology of Man*, Vol. II, *Alimentation, Digestion*, &c., New York, 1867, p. 393 *et seq.*

fæces. The presence of undigested food in considerable quantities and recognizable by the naked eye constitutes the condition known to the ancients as lientery, which is more common in the chronic forms of diarrhœa and dysentery, and which will be referred to again hereafter.

Chemical examinations of the stools in diarrhœa have been made by Simon,* Lehmann,† Ihring,‡ and others. They still leave much to be desired. One of the most important facts established is the presence of considerable quantities of albumen in the liquid discharges.§

On *microscopical examination*, besides debris of food in quantities largely dependent upon the character of the diet, we find: 1. Corpuscles similar to the white corpuscles of the blood, which may be described as mucous corpuscles when they occur in glairy masses of mucus visible to the naked eye; as pus-corpuscles when they are thickly crowded together in an albuminous serum so as to form a yellowish opaque fluid. This latter condition is more common in acute and chronic dysentery. In either case the appearances presented by the corpuscles are identical, and their origin is probably the same; that is, they are to be regarded as white blood-corpuscles which have migrated into the intestinal tube from the bloodvessels of the inflamed mucous membrane. The number of these bodies, and their association with mucus or their aggregation as pus, afford valuable indications as to the intensity of the inflammatory process. 2. Red blood-corpuscles, variously deformed by their sojourn in the intestines, can often be recognized when the presence of blood cannot be detected by the naked eye. In consequence of the changes they have undergone they often give to the stools a blackish or brownish hue. Much more common in chronic cases, in dysentery, and in the peculiar diarrhœa of typhoid fever, they nevertheless are frequently encountered in considerable quantities in severe cases of acute diarrhœa. 3. Epithelial elements derived from the intestinal mucous membrane have also been observed, but according to my observations are not of frequent occurrence. 4. Crystals of the triple phosphates of ammonia and magnesia are very commonly found whenever the liquid stools are alkaline, which is usually the case. 5. Besides the foregoing, various low vegetable forms are of constant occurrence. These have recently acquired considerable interest on account of their supposed relation to the causation of diarrhœa, as similar organisms have been supposed to act as the cause of dysentery, typhoid fever, cholera morbus, Asiatic cholera, and other diseases. Their occurrence in the stools of diarrhœa will, however, appear less significant if their abundance in the normal fæces is fully understood.

My own observations have satisfied me that a large part of the substance of normal human fæces is made up of these low forms, in numbers which must be estimated by hundreds of millions in the fæces of each day. When a small fragment of the normal fæces, taken immediately after it is voided, is shaken into an emulsion with distilled water and examined with an adequate power, these forms are found floating in countless multitudes along with fragments of partly digested muscular fibres and other debris from the food. They consist of extremely minute spherical elements, elongated rod-like forms, and larger elliptical bodies, resembling torula cells. All these can be recognized by a practiced observer with a good $\frac{1}{5}$th of an inch objective, but for their closer study the highest powers of

* *Loc. cit.* † *Loc. cit.*

‡ IHRING—*Mikroscopisch-Chemische Untersuchungen menschlichen Fæces unter verschiedenen Pathologischen Verhältnissen*, Inaug. Diss., Giessen, 1852. I have not seen this thesis, a short abstract of which will be found in the British and Foreign Medico-Chirurgical Review, Vol. XIV, 1854, p. 529.

§ According to IHRING, albumen is found in the stools of dysentery and various forms of diarrhœa, but not in the loose discharges produced by purgative medicines administered to healthy individuals.

the microscope are desirable. I have found immersion objectives of $\frac{1}{10}$th to $\frac{1}{25}$th of an inch equivalent focal length best adapted to the investigation; with these, by proper eye-pieces, quite as high powers can be obtained as are given by objectives of shorter focal length, and with better definition. The spherical elements are the most numerous of all; they are smooth, transparent, highly refractive bodies, which vary from $\frac{1}{20000}$th to $\frac{1}{30000}$th of an inch in diameter or even less, and are in continual active movement. If a drop of the emulsion is placed beneath a thin cover and a ring of varnish applied to the edges to prevent evaporation, this motion will be found to continue indefinitely. Between these elements and the rod-like ones all possible transition forms exist. The rod-like bodies themselves are similar in their appearance to the spherical ones in everything except form, and are exceedingly numerous. They may attain the $\frac{1}{8000}$th or even the $\frac{1}{5000}$th of an inch or more in length without exceeding the $\frac{1}{20000}$th of an inch in breadth. As a rule, they do not possess the active movements of the spherical elements, but float with the currents of the fluid, remaining stationary when it comes to rest, or progressing slowly with a slight sinuous motion. On the other hand, rod-like bodies quite similar to the others are frequently observed, which appear to possess a proper motion as active as that of the spherical forms. The rod-like bodies often occur in pairs placed end to end; sometimes several of them are thus arranged in the form of a filament. The spherical elements are also frequently arranged in little chains like strings of beads. As far as can be ascertained, the foregoing forms do not differ from those ordinarily encountered in putrescent nitrogenous mixtures. They constitute in their totality what Béchamp and Burdon-Sanderson have described under the designation of microzymes,* and Billroth† under that of coccobacteria septica. The spherical forms are the micrococcus of Hallier,‡ the sphærobacteria of Cohn;§

* A. BÉCHAMP—*Note sur les granulations moleculaires des fermentations et des tissus des animaux.* (Read to the Acad. of Sciences, Feb. 24, 1868.) Arch. Gén. de Méd., 1868, T. I, p. 492. BURDON-SANDERSON—*Introductory Report on the intimate Pathology of Contagion*—Twelfth Report of the Medical Officer of the Privy Council, for 1869, London, 1870, p. 245; also, *Further Report on the intimate Pathology of Contagion*—Thirteenth Report of the same, for 1870, London, 1871, p. 48.

† THEODOR BILLROTH—*Untersuchungen über die Vegetationsformen von Coccobacteria Septica und den Antheil, welchen sie an der Entstehung und Verbreitung der accidentellen Wundkrankheiten haben*, Berlin, 1874. According to this author all the vegetable forms as yet observed in contagious diseases, as well as in the various forms of putrefaction which interest the physician and surgeon, belong to the several stages of development of one genus, which he classes with the algæ, and designates *Coccobacteria septica*. The spherical forms he calls *coccos*, and groups them in accordance with their small, medium or comparatively large size, as *micrococcus*, *mesococcus* and *megacoccus*; chains or filaments composed of the spherical forms arranged in rows, he names *streptococcus*; pellicles of the same, *petalococcus*; masses of them held together by a slimy or gelatinous material, *gliacoccus*. The rod-like bodies which he designates *bacteria* are also spoken of according to their size, as *micro-*, *meso-* and *megabacteria*; in filaments composed of segments placed end to end, as *streptobacteria*, in pellicles as *petalobacteria*, and in gelatinous masses as *gliabacteria*. Bacteria develop out of coccus under various circumstances; moreover, in the bacteria-rods there are developed under particular conditions certain minute dark contoured spherical bodies, which are the true spores (Daursporen) of the plant, which resist extremes of heat and cold, which are not destroyed by drying, and which are hence the most important agents in the transmission of coccobacteria from place to place. When these spores meet a suitable soil they develop into coccus, or bacteria, or both. ‡ For the titles of HALLIER'S various papers see a subsequent note.

§ FERDINAND COHN—*Untersuchungen über Bacterien*, Beiträge zur Biologie der Pflanzen, Bd. I, Heft 2, Breslau, 1872, S. 127; Bd. I, Heft 3, Breslau, 1875, S. 141; Bd. II, Heft 2, Breslau, 1876, S. 249—does not accept the view of BILLROTH that the rod-like forms develop out of the spherical ones. In the first paper cited he offered the following provisional classification of the forms in question. Tribe I, Sphærobacteria, (Sphere-bacteria.)

the rod-like ones were formerly called vibrios, but are now generally known as bacteria; the filaments and chains have been designated leptothrix by Hallier, streptococcus and streptobacteria by Billroth, desmobacteria by Cohn. The torula-like cells are elliptical in form, with a double contour and faintly granular contents. Usually they contain a single central nucleolus-like body, sometimes two of them. They occur singly, or in chains of two or three cells, in which case one is usually much smaller than the others. The number of these elements in the healthy fæces is small as compared with the innumerable swarm of spherical and rod-like bacteria; it is, moreover, exceedingly variable; never, however, have I found them entirely absent.

The presence of micrococci, bacteria and torula-like forms in the normal fæces has been heretofore noted by several observers.* Hallier† himself has pointed out that micrococci occur abundantly in the contents of the human intestinal canal in the healthy condition. But these observations have not attracted the attention they deserve, and most of the modern text books on physiology make no mention of the presence of these vegetable forms in their account of the fæces.‡

In the stools of acute diarrhœa, and indeed of acute and chronic dysentery, the low vegetable forms just described are invariably present, and no other more specific forms have as yet been observed.§ The micrococci and bacteria do not appear to be more numerous than in healthy fæces; but it frequently happens that the torula-like forms occur much more abundantly than in the normal condition. This especially happens in chronic cases, in which the starchy elements of the food are passed in a partly digested condition, consti-

---

Genus 1, Micrococcus. Tribe II, Microbacteria, (Rod-bacteria.) Genus 2, Bacterium. Tribe III, Desmobacteria, (Thread-bacteria.) Genus 3, Bacillus. Genus 4, Vibrio. Tribe IV, Spirobacteria, (Screw-bacteria.) Genus 5, Spirillum. Genus, 6, Spirochæte. In the second paper he energetically combats the views of BILLROTH, and not only maintains these genera, but adds many others, making a still more elaborate classification which embraces about forty genera. He regards these organisms as more nearly allied to the algæ (especially to the *Phycochromaceæ*) than to the fungi, (p. 201,) and suggests the term *Schizophytæ* as a better family name than *Schizomycetes* proposed by NAEGELI, which is only applicable on the supposition that they are allied to the fungi.

* Thus, GROS—*Observations et Inductions Microscopiques sur quelques Parasites*, (Extr. du Bullet. de la Société Imp. des Natur. de Moscou, Tome XVIII, 1845,) p. 51—states that human excrement, whether healthy or diseased, swarms with vibrios: "les excréments humains ou sains ou malades fourmillent de vibrions de grandeur diverse." He adds: "Les médicaments ne semblent pas en diminuer le nombre et la vivacité." FRERICHS—*Wagner's Handwörterbuch der Physiologie*, Bd. III, Abth. 1, Braunschweig, 1846, S. 869—under the head of "Pilzbildung im Verdauungscanal," mentions, besides the occurrence of torula cerevisiæ, certain thread-like forms ("Fadenpilze") and their accompanying spores, which he states are found in the large intestine, where, as usual with these forms, they precede and accompany that spontaneous putrefaction which frequently occurs in the lower part of the intestinal tract. He figures these filaments and spores in Taf. V, Fig. 15. F.A. LONGET—*Traité de Physiologie*, 2me édit., T. I, Paris, 1861, p. 284—says, speaking of the contents of the digestive tube: "On rencontre très souvent des conferves qui se développent sur le contenu de l'intestin, sans troubler la digestion; d'autres fois leur formation est un signe que la digestion est altérée par quelque disposition morbide des organes." FREY—*Das Mikroskop und die Mikroskopische Technik*, 5te Auflage, Leipzig, 1873, S. 269—"Der Koth des Menschen ist stets sehr reich an Fäden und Trümmern der Leptothrix." OTTO HAUSMANN—*Ueber Vibrionäre Parasiten*, Inaug. Diss., Berlin, 1870, S. 28—states that bacteria are more numerous and more fully developed in fluid stools, whether due to disease or the administration of medicines, than in the more solid healthy excrement; which does not agree with my own observations. He does not, however, think that they can be regarded as the cause of diarrhœal diseases: "Diese Thatsachen beweisen vollkommen, dass die Vibrionen an Diarrhœen und Cholera-Zufällen vollkommen unschuldig sind," S. 29. According to BILLROTH (*op. cit.*, p. 94) the meconium of new-born children contains no trace of these vegetable forms, but even the very first yellow stool of the new-born child is rich in them. The contents of the human stomach, as found in autopsies made shortly after death, and of the stomachs of animals just killed, usually present but few of these forms; on the other hand, they abound in the small intestine, and especially in the large—"Der Dünndarm aber und besonders der Dickdarm ist voller mittelgrosser theils ruhender, theils beweglicher Vegetationen der Fäulnissalge." In the diarrhœal stools of patients suffering with typhus, lead-colic and traumatic peritonitis, examined just after they were passed, mesobacteria, single and in chains, were as abundant as in putrefying flesh-water; but the same was true of the fluid stools of a healthy woman who, a few hours before, had taken a saline purge, (eine grosse Dosis Bitterwasser.)

† *Pilz-Regulativ*, Jena, 1870, S. 29; also *Parasitologische Untersuchungen, bezüglich auf die pflanzlichen Organismen bei Masern, Hungertyphus, Darmtyphus, Blattern, Kuhpocken, Schafpocken, Cholera nostras*, &c., Leipzig, 1868, S. 65. See also the translation of this essay in Vol. III of the Publications of the Massachusetts Medical Society, Boston, 1872, p. 344.

‡ See, for example, WILLIAM B. CARPENTER—*Principles of Human Physiology*, 7th edit., London, 1869, p. 149; JOHN C. DALTON—*A Treatise on Human Physiology*, 5th edit., Philadelphia, 1871, p. 148; AUSTIN FLINT, jr.—*The Physiology of Man*, Vol. II, *Alimentation, Digestion*, &c., New York, 1867, p. 393. Dr. LIONEL S. BEALE—*The Microscope in its Application to Practical Medicine*, Am. reprint of the 3d London edit., Philadelphia, 1867, p. 194—in his account of the microscopical "examination of matters passed by the bowels," though he states that "vast numbers of vibriones, with different kinds of vegetable fungi, are not uncommonly found" in the stools of typhus, makes no mention of their occurrence in the normal fæces.

§ For HALLIER's account of the fungus supposed to cause diarrhœa, see his elaborate essay, *Die Parasiten der Infectionskrankheiten*, Zeitschrift für Parasitenkunde, Bd. I, 1869, S. 174; also Taf. IV, fig. 51; for that of dysentery, see the same essay, S. 176, and Fig. 52 of the same plate. The forms represented in the two figures are remarkably like those always encountered in normal human excrement, a resemblance which Hallier himself expressly admits, S. 175. The low vegetable forms in diarrhœa stools have also been described by J. M. KLOB—*Path.-Anat. Studien über das Wesen des Cholera-processes*, Leipzig, 1867—who found groups of bacteria, (Bacterienhäufchen,) short filaments (Leptothrix-Gliederketten) and micrococci, (Schwärmsporen.) These elements offered no characteristic differences from those observed by the same author in the stools of dysentery and Asiatic cholera.

tuting the gelatinous-looking masses which will be described hereafter in connection with the stools of dysentery.*

This apparent identity of the cryptogamic forms found in the stools of diarrhœa and dysentery with those that swarm in normal excrement might seem to dispose of the hypothesis that they produce the morbid conditions in which they occur. But this objection has been met by Hallier † with the assertion that the organic forms actually observed in these several conditions are merely immature phases of higher organisms, and that although they may appear to be identical they are in reality diverse. This he claimed to have demonstrated by his culture experiments, in which the micrococci derived from various diseases seemed to develop, in part at least, into characteristic species of microscopic fungi peculiar to each disease.

But those who have most carefully repeated Hallier's experiments have not obtained identical results. De Bary and Hoffmann ‡ have shown that, altogether aside from the question of their pathological significance, his hypotheses are untenable from the strictly botanical point of view. In fact the vegetable forms in question are so minute, occur in such countless multitudes, and are so often inseparably intermixed in the same fluid, that their natural history offers excessive difficulties. Burdon-Sanderson § in some of his experiments saw torula forms originate in vast numbers, and develop into luxuriantly fructifying fungi (e. g. penicilium, &c.,) without the appearance of any microzymes in the fluid; and the weight of evidence certainly appears to be against the notion that these lower forms ever develop into higher ones. The relation of the lower forms to each other, however, offers such difficulties that the botanists themselves have been unable to agree with regard to it. According to Burdon-Sanderson, the spherical forms (micrococcus) develop into the elongated ones, (bacteria,) and these again elongate by cell-division into filaments. Billroth ‖ adopts the same view, and describes the formation in the elongated forms of resting-spores (Dauersporen) by the multiplication of which the spherical forms are again generated. According to this view, the spherical forms, the rods and the chains, constitute but a single genus, which presents a great variety of appearances in accordance with the stage of its development and the soil on which it is grown. On the other hand, there are botanists who, like Cohn,¶ regard the transformation of the spherical forms into rods and chains as undemonstrated, and think these low forms constitute several independent genera, with regard to the exact number and limits of which there is much diversity of opinion. These humble forms arise whenever nitrogenous substances putrefy,** and hence make their

* The torula-like forms, under these circumstances at least, would appear to be identical with the ordinary yeast fungus. Their occurrence in the stools under the circumstances mentioned in the text has been especially insisted upon by J. H. SALISBURY—*Chronic Diarrhœa and its Complications*, &c., &c.—in the Annual Report of the Surgeon General of Ohio for 1864, p. 25.

† With regard to HALLIER'S views as to the specific fungi of various diseases, see, besides the papers already quoted, *Die Pflanzlichen Parasiten des menschlichen Körpers*, Leipzig, 1866; *Gährungserscheinungen: Untersuchungen über Gährung, Fäulniss und Verwesung, mit Berücksichtigung der Miasmen und Contagien sowie der Disinfection*, Leipzig, 1867; *Das Cholera-Contagium*, Leipzig, 1867; (see also an abstract of this essay by Dr. Buchanan, in the *Ninth Report of the Medical Officer of the Privy Council*, London, 1867, p. 512;) *Phyto-pathologie*, Leipzig, 1868; also various essays in the Zeitschrift für Parasitenkunde, Jena, 1869, and subsequently, besides the essay, *Die Parasiten der Infectionskrankheiten*, already quoted, which is continued as a serial in that journal, Bd. I, S. 117 and 291; Bd. II, S. 67 and 113; Bd. III, S. 7 and 157, and Bd. IV, S. 56.

‡ A summary statement of the objections of DE BARY and H. HOFFMANN, as well as of those of KARSTEN and BONORDEN, is given by EDUARD EIDAM—*Der gegenwärtige Standpunkt der Mycologie mit Rücksicht auf die Lehre von den Infections-Krankheiten*, Berlin, 1871.

§ See particularly the second paper cited in the note *supra*. ‖ *Op. cit.* ¶ See note *supra*.

** The question of the mode of their origin has given rise to a controversy which is still going on. On the one hand, it is held that they arise only when the germs are supplied, and it is contended that these germs are always present in air and water; on the other, it is maintained that whenever the necessary conditions are supplied the forms will originate, even if all the germs present have previously been destroyed and the access of others rendered impossible; in other words, that under favorable conditions spontaneous generation occurs. The literature of this subject is so extensive that I will not even attempt to enumerate the principal works. Among the most important may be mentioned the various essays of POUCHET and PASTEUR, who have warmly discussed the subject in France, [see *Comptes rendus de L'Acad. des Sciences*, passim, especially from 1858 to 1869,] and those of BASTIAN and TYNDALL in England. [H. C. BASTIAN—*The Modes of Origin of Lowest Organisms*, London, 1871; *The Beginnings of Life*, London, 1872, and other subsequent papers—is one of the most plausible defenders of the doctrine of spontaneous generation. On the other hand, the experiments of J. TYNDALL—*The optical deportment of the atmosphere in relation to the phenomena of putrefaction and infection*, Phil. Trans., Vol. 166, Part 1, 1876, p. 27; *A combat*

appearance in animal tissues undergoing necrosis even while these are still attached to the living body. From such local foci of development it is asserted that they may find their way into the torrent of the circulation, by which they are transported to distant organs, where they lodge, multiply and set up metastatic processes of diverse kinds. Since the first publication of Hallier, the number of those who seek in these vegetable forms the causes of various infectious diseases has continually increased.* It is true that all attempts to indicate distinctions between the form or development-history of the micrococci and bacteria supposed to cause various diseases, or between these and those which occur in ordinary putrefying nitrogenous substances, have hitherto completely failed, but that circumstance has not shaken the faith of those who have adopted this view. Compelled to abandon the morphological basis upon which the hypothesis was at first erected, they have sought a fresh support for it in inoculation experiments;† but as hitherto performed these are far from conclusive; for, although by filtration, diffusion and other devices, it seems to be pretty conclusively shown that the infection resides in solid particles rather than in the fluid in which they float, no methods of separating the vegetable forms from particles of diseased protoplasm‡ derived from the morbid tissues have as yet been devised. The question cannot, however, be regarded as settled, and it is probable that it will continue to be made the subject of experimental inquiry for some time to come.

with an infective atmosphere; Lecture delivered at the Royal Institution, Jan. 19, 1877, British Med. Journ., Jan., 1877, p. 95; and other papers—would seem almost conclusive against this view.] An interesting American paper on the subject is that of JEFFRIES WYMAN, *Observations and Experiments on living Organisms in heated water*, The American Journal of Science and Arts, 2d series, Vol XLIV, (1867,) p. 152.

* The literature, to which the study of the supposed causation of disease by minute vegetable forms has given rise since the first publications of HALLIER, is so voluminous that only the most industrious specialist can hope to make a complete survey of it. The best introduction to the study of the subject with which I am acquainted will be found in two series of reviews in *Schmidt's Jahrbücher*; viz., H. E. RICHTER—*Die neuern Kenntnisse von den krankmachenden Schmarotzerpilzen*, op. cit., Bd. 135, [1867,] S. 81; Bd. 140, [1868,] S. 101; Bd. 151, [1871,] S. 313; Bd. 159, [1873,] S. 169. The author of these reviews was a convert to the doctrines of HALLIER, notwithstanding which he gives very fair abstracts of most of the important works on the subject. A less partisan stand-point was maintained in a later series of reviews in the same Journal by F. V. BIRCH-HIRSCHFELD; viz., Review of the work of COZE and FELTZ, *op. cit.*, Bd. 154, [1872,] S. 236; Review of the work of RAVITSCH, *op. cit.*, Bd. 156, [1872,] S. 326; and especially two elaborate reviews, in each of which a number of works are discussed; viz., *Die neuern path.-anat. Untersuchungen über krankmachende Schmarotzerpilze*, op. cit., Bd. 155, [1872,] S. 97, and *Die neueren path.-anat. Untersuchungen über Vorkommen und Bedeutung niederer Pilzformen (Bakterien) bei Infektionskrankheiten*, op. cit., Bd. 166, [1875,] S. 169. The more important American papers on the same subject are the "*Report of Results of Examinations of Fluids of Diseased Cattle with reference to Presence of Cryptogamic Growths*," by Assistant Surgeons J. S. BILLINGS and E. CURTIS, U. S. A., in the Report of the Commissioner of Agriculture, on the Diseases of Cattle in the United States, Washington, Government Printing Office, 1871, p. 156; J. C. DALTON—*The Origin and Propagation of Disease*, New York, 1874; L. A. STIMSON—*Bacteria and their influence upon the origin and development of septic complications of wounds*, The New York Medical Journal, Aug., 1875, p. 113; W. H. VAN BUREN—*On the Poisons which interest the Surgeon*, New York Med. Jour., Nov., 1875, p. 449, and Dec., 1875, p. 561; T. E. SATTERTHWAITE—*Bacteria, their nature, and relation to disease*, The New York Med. Record, Dec. 18, 1875, p. 853; and F. A. P. BARNARD—*The Germ theory of disease and its relations to hygiene*, Reports and papers presented at the meetings of the American Public Health Association in the year 1873, p. 70.

† Notwithstanding numerous recent works, the position of the question has not materially changed since the admirable presentation of this phase of the argument by VIRCHOW—*Die Fortschritte der Kriegsheilkunde besonders im Gebiete der Infectionskrankheiten*, Berlin, 1874. I translate two striking paragraphs: "Although we may be unable directly to see these inner differences in such minute bodies as vibrios and bacteria, yet we ought to remember that in the case of the formative cells of the ovule, and of numerous pathological growths, although they appear as gigantic forms alongside of vibrios, we are unable to predict what will grow out of them—yea, eggs themselves are often so similar to each other that the differences of the animals which will proceed from them cannot be suspected in the least degree." "If, therefore, it results from an inoculation or a pathological accident that milzbrand arises from bacteria which are perfectly like those of common putrid infusions, while the bacteria of the common infusions will not develop it, we shall be obliged to conclude that the bacteria of milzbrand are at least as different from the bacteria of the infusion as hemlock from parsley," [p. 33.] In the inoculation experiments which are thought to support this view various devices have been employed to separate the solid particles of the inoculating material from the fluid in which they float; such, for example, as diffusion, practiced first with vaccine matter by A. CHAUVEAU—*Nature du virus-vaccin*, (three notes read to the Academy of Sciences, February, 1868,) Gazette Méd. de Paris, T. 23, [1868,] p. 138; also Archives Gén. de Méd, 1868, T. I, p. 488—and in a somewhat modified way by BURDON-SANDERSON, [p. 234 of his first paper, cited *supra*, on page 279;] filtration, especially drawing the virus experimented with through a clay cylinder used as a filter by means of a Bunsen's air-pump, as practiced with material derived from pyæmic abscesses of the lung by TIEGEL—*Ueber die fiebererregende Eigenschaft des Microsporon septicum*, Bern, 1871, [see Schmidt's Jahrb., Bd. 155, 1872, S. 103;] and freezing as practiced by E. BERGMANN—*Zur Lehre von der putriden Intoxication*, Deutsche Zeitschrift für Chirurgie, Bd. I, [1872,] S. 373. The objection made in the text to the interpretation so often put upon these experiments was, so far as I know, first clearly stated by F. A. KEHRER—*Ueber das putride Gift*, Archiv für Exp. Pathologie u. Pharmakologie, Bd. II, [1874,] S. 33: "It cannot yet be concluded, I think, that because the sepsin cannot be filtered through clay cells and destroyed by boiling, vibrios or other low animal or vegetable forms contain the sepsin in their bodies or develop it by their tissue metamorphosis; for with our present experimental methods it is impossible to separate these organisms from other molecules which are found along with them. It would be better for exact research to indicate openly the limits of our present knowledge, than to fill existing gaps by undemonstrated suppositions, which may perhaps acquire the appearance of truth to those unacquainted with the facts, (den ferner Stehenden.)" [S. 61.]

‡ LIONEL S. BEALE—*Disease Germs; their supposed nature*, London, 1870; and *Disease Germs; their real nature*, London, 1870—has ingeniously advocated the view that the molecules of diseased protoplasm, or, as he prefers to call it, bioplasm, are the essence of the contagion rather than the associated vegetable forms. According to him, "The minute contagious bioplast is less than the 1-100,000 of an inch in diameter, and often so very clear and structureless as to be scarcely distinguishable from the fluid in which it is suspended." [Second work named above, p. 159.] See also the *Report on the Cattle-plague, to the Royal Commissioners*, London, 1866, by the same author.

Among the diseases whose cause has been sought in the low organisms just described, perhaps none has been more thoroughly studied than the splenic fever of animals, (Milzbrand.) This disease is capable of infecting man, producing ordinarily the so-called malignant pustule, in certain cases of which necrotic hæmorrhagic patches or diphtheritic sloughs are found after death in the mucous membrane of the stomach and intestines; sometimes, also, such patches or sloughs occur when no external lesion has been recognized. In these patches micrococci and bacteria have been found in great abundance, just as we shall hereafter see occurs in the sloughs of diphtheritic dysentery. The morbid condition has hence been designated Mycosis intestinalis. It is usually associated with a brisk catarrh of the mucous membrane of the stomach or intestines, or both, and vomiting and purging often precede the fatal collapse, which, however, occurs also when one or both of these symptoms are wanting, as in fatal cases of the same infection in which the alimentary canal is not affected at all. No cases of this accident were observed during the war; but, as the subject is one of great interest, I subjoin in a footnote an outline of its literature.*

The *odor* of the stools usually becomes strikingly modified after the diarrhœa has lasted a short time. While the passages remain feculent the normal fæcal odor may be retained; but when they become watery or mucous, it is replaced by a peculiar nauseous smell, and in the advanced stages of graver cases, especially in fatal cases for a short time

* The first accounts of Mycosis intestinalis will be found in the papers of E. v. WAHL—*Ueber einen Fall von Mykose des Magens*, Virchow's Archiv, Bd. XXI, 1861, S. 579; F. v. RECKLINGHAUSEN—*Mykose der Magenschleimhaut*, Virchow's Archiv, Bd. XXX, 1864, S. 366; and NICOLAS ZALESKY—*Ein Fall von Soor im Magen*, Virchow's Archiv, Bd. XXXI, 1864, S. 426; each of whom has described a single case. Then followed the more elaborate papers of LUDWIG BUHL—*Mycosis intestinalis*, Zeitschrift für Biologie, Bd. VI, 1870, S. 129—who reported an additional case, and of WALDEYER—*Mycosis intestinalis*, Virchow's Archiv, Bd. LII, 1871, S. 541—who reported two, and expressed the belief that the disease was really a manifestation of milzbrand. Then followed the brief communication of GREGOR MÜNCH—*Mycosis intestinalis und Milzbrand*, Centralblatt für die medicinischen Wissenschaften, December, 1871, S. 802—who stated that he had made, since 1867, twenty-eight autopsies of persons dead of malignant pustule, in the workmen's hospital at Moscow, with results perfectly corresponding to those of Buhl and Waldeyer; the publication of two cases by A. BURKART—*Ein Fall von Mycosis intestinalis*, Berliner Klinische Wochenschrift, 1873, No. 13, S. 145, and *Ein Fall von Pilzembolie*, op. cit., 1874, No. 13, S. 149; of four cases by E. WAGNER—*Die intestinal Mycose und ihre Beziehung zum Milzbrand*, Archiv für Heilkunde, 1874, Heft 1, S. 1—whose paper contains an excellent discussion of the previous literature of the subject; three cases by W. O. LEUBE and W. MÜLLER—*Drei Fälle von Mycosis intestinalis und deren Zusammenhang mit Milzbrand*, Deutsches Archiv für Klinische Med., Bd. XII, [1874,] S. 517; two by B. FRÄNKEL and J. ORTH—*Zwei Fälle von Milzbrand beim Menschen*, Berliner Klin. Wochenschrift, Nos. 22 and 23, 1874; and one by GERALD YEO—*Mycosis intestinalis*, Dublin Jour. of Med. Sci., September, 1875, p. 256. Some of these cases are no doubt open to the objection raised by VIRCHOW in a note appended to v. WAHL'S case, and repeated by v. RECKLINGHAUSEN in his comments on his own case, that the autopsies were made so long after death as to suggest the probability that the fungi found were the mere concomitants of cadaveric putrefaction. But this cannot be urged against all the cases, and when it is considered that the vegetable forms found in milzbrand can in no way be distinguished from those of ordinary putrefaction or of the normal contents of the alimentary canal, it seems probable enough that the forms found in the sloughs of mycosis intestinalis may be derived from the same source as the similar forms, which will hereafter be described, in the dysenteric sloughs; viz., from the bacteria normally present in the intestinal contents, which promptly invade the sloughs so soon as they begin to putrefy, even during the life of the subject. The most popular view at the present time, however, is that mycosis intestinalis results from inoculation with virus containing the specific vegetable forms supposed to cause milzbrand, and that the gangrenous patches in the intestine proceed from the localization of these forms. These vegetable forms were first observed by POLLENDER—*Mikroskopische und Mikrochemische Untersuchung des Milzbrandblutes*, &c., Casper's Vierteljahrsschrift für ger. u. öff. Medicin, Bd. VIII, [1855,] S. 103; and BRAUELL—*Versuche und Untersuchungen betreffend den Milzbrand des Menschen und der Thiere*, Virchow's Archiv, Bd. XI, [1857,] S. 132; and *Weitere Mittheilungen über Milzbrand und Milzbrandblut*, Ib., Bd. XIV, [1858.] S. 432. They were afterwards elaborately studied by DAVAINE—*Recherches sur les infusoires du sang dans la maladie connue sous le nom de sang de rate*, Comptes rendus de l'Acad. des Sciences, T. LVII, [1863,] pp. 220, 351 and 386, and T. LIX, [1864,] p. 393—and quite recently under the supervision of COHN by KOCH—*Die Aetiologie der Milzbrand-krankheit, begründet auf die Entwicklungsgeschichte des Bacillus Anthracis*, Cohn's Beiträge zur Biologie der Pflanzen, Bd. II, Heft 2, Breslau, 1876, S. 277, with plate. POLLENDER described these forms as presenting the closest resemblance to "vibrio bacillus" or "vibrio ambiguus;" DAVAINE called them "bactéridia;" KOCH, who names them "bacillus anthracis," gives no characteristics adequate to distinguish them from the bacillus subtilis of COHN (which are found in ordinary butyric acid fermentation, &c.) except the fact that they occur in milzbrand. The reader who desires to become acquainted with the general subject of milzbrand is referred particularly to the following works: C. F. HEUSINGER—*Die Milzbrandkrankheiten der Thiere und des Menschen*, Erlangen, 1850; R. VIRCHOW—*Die Carbunkelkrankheit beim Menschen*. Handb. der spec. Path. u. Ther., Bd. II, Abth. 1, Erlangen, 1855, S. 394; L. A. RAIMBERT—Art. *Charbon*, in the Nouv. Dict. de Méd. et de Chir. Prat., T. VII, Paris, 1867, p. 179; KORÁNYI—*Der Milzbrand*, Handb. der allg. u. spec. Chir. v. Pitha u. Billroth, Bd. I, Abth. 2, Erlangen, 1870, S. 149; O. BOLLINGER—*Beiträge zur vergleichenden Path. u. Path. Anat. der Hausthiere*, Heft 2, Munich, 1872; also the article *Milzbrand* by the same author, in ZIEMSSEN'S Handb., Bd. III, Leipzig, 1874, S. 447, (Amer. Transl., Vol. III, New York, 1875, p. 372.) It will be learned from the earlier of these works that long before mycosis intestinalis was recognized, hæmorrhagic, gangrenous or diphtheritic patches were occasionally observed in the mucous membrane of the stomach and intestines of human subjects dead of milzbrand. Among those who are liable to this affection, workers in hair may be particularly mentioned. I subjoin the titles of papers describing two outbreaks of "malignant pustule," so-called, among hair-workers, in which the intestinal lesions alluded to were observed in some of the autopsies, but not identified as mycosis intestinalis: J. NEYDING—*Beitrag zur path. Anat. der Pustula maligna beim Menschen*, Casper's Vierteljahrsschrift f. ger. u. öff. Medicin, Bd. X, N. F., [1869,] S. 241—describes the occurrence of a number of cases among workers in hair and bristles in Moscow; five autopsies were made, and the gastro-intestinal lesions were recognized in four of them; SILAS E. STONE—*Cases of malignant pustule*, Boston Med. and Surg. Jour., Vol. I, N. S., [1868,] p. 19, and *Malignant vesicle*, Ib., Vol. III, N. S., [1869,] p. 21—reports 13 cases occurring among the persons working in, or connected with, a hair factory near Walpole, Mass. MORRILL WYMAN, in an autopsy on one of these cases, observed "ecchymosed patches" in the intestinal mucous membrane. Bacteria were observed in the blood of some of these patients by JEFFRIES WYMAN and HODGES. See Boston Med. and Surg. Jour., Vol. II, N. S., [1869,] p. 359.

before death, the odor becomes very offensive, approximating that of putrefying organic matter, and well deserving the epithet cadaverous, which has frequently been applied to it. Even when the odor of the dejecta is not at all offensive immediately after they are voided, it will usually be observed that putrefaction occurs much earlier than it does in the normal fæces, and that if the stools are kept for the inspection of the medical attendant they are apt to be found by him in a much more offensive condition than when they were first passed.

This circumstance has been commented on by Dr. T. Inman, of Liverpool,* who explains it by supposing the absence of the putrefactive odor in the case of the normal fæces to be due to the possession by the excreta of "a certain vital power" which enables them to resist the tendency to decomposition, and which being diminished in disease permits putrefaction to occur. In this explanation the doctrine of vital force is pushed to an extreme which may well provoke a smile, and certainly it would seem that a much simpler explanation may serve to account for the phenomena. That the normal fæces do not putrefy in the large intestine before they are voided is due partly to the almost total absence of oxygen from the gases of both small and large intestine under normal conditions,† and partly to the presence of certain substances which appear to exert an antiseptic influence, among which one of the most important is, perhaps, the bile.‡ It has been shown by several experimenters that when a biliary fistula is established in a dog, and the bile thus prevented from entering the intestinal canal, putrid decomposition of the alimentary substances takes place, giving an offensive odor to the fæces and flatus, at least so long as the

* T. Inman—*On the Influence of Vitality upon the Excretions.* The British Medical Journal, April 30, 1859, p. 350, June 11, 1859, p. 461, and July 2, 1859, p. 523.—"The fæces, retained though they be sometimes for days, and in some rare cases for weeks and months, in the colon or the rectum, do not decompose there, as they do when they are expelled from the body; and this observation holds good, even though the bowels are distended with flatus, and the fæcal matter is in contact with a gas differing in no degree from common atmospheric air." "We account for this by saying that the excreta have a certain vital power as long as they remain in the body, which enables them to resist the ordinary laws governing the inorganic world. But we know from experience that the vital power does not immediately leave a limb after it has been amputated; and it becomes, therefore, a question whether vitality may not also remain in excretions for some time after their expulsion from the body," p. 461. Dr. Inman then points out that in healthy infants the motions retain their peculiar odor "for twelve hours at least;" but that, if "the child loses its healthy condition, the motions not only change in color and consistence, but in smell, and decompose in a very short time after being passed. Where there is diarrhœa and excessive depression of the vital powers, the motions are often found to be decomposed in a few minutes." He shows that this observation holds good also in the case of adults laboring under diarrhœa, and that "decomposition takes place in the alvine secretions very rapidly in fevers and all diseases marked by great debility." In the same diseases the urine decomposes more rapidly than the urine of healthy persons. Dr. Inman argues that the speedy decomposition in all these cases is due to the excreta of debilitated individuals being endowed with less than the normal amount of vitality, and concludes that "If the physician finds that the excretions of any of his patients decompose more rapidly than they would do during health, (under the same external circumstances of light, air and heat,) he may feel certain that the vital powers are seriously impaired," p. 462. With this conclusion we may at least agree so far as to admit that speedy decomposition occurs only when the quality of the excreta is abnormal.

† See F. A. Longet—*Traité de Physiologie*, 2me edit., Paris, 1861, Tome I, p. 282; Wm. B. Carpenter—*Principles of Human Physiology*, 7th edit., London, 1869, p. 150; Austin Flint, Jr.—*The Physiology of Man: Alimentation, &c.*, New York, 1867, p. 411—and other recent text-books of physiology.

‡ William Saunders—*A treatise on the Structure, Economy and Diseases of the Liver, &c.*, 2d edit., London, 1795—appears to have been the first to have suggested this use of the bile: "It seems very probable, that from its resinous bitter, it may counteract any active and spontaneous changes to which animal and vegetable matter would otherwise be subject." p. 127. "It likewise, from its bitterness, possesses antiseptic powers, which are peculiarly useful in the intestinal canal." p. 130. Tiedemann and Gmelin—*Recherches Expérimentales, Physiologiques et Chimiques, sur la Digestion*, Traduites de l'Allemand par A. J. L. Jourdan, Paris, 1826, 2de Partie, pp. 48 and 71—found that when the common bile-duct was tied in dogs the stools became putrid, and a comparatively large quantity of offensive gas was developed in the alimentary canal. They also pointed out that in the human subject jaundice is accompanied by fetid dejecta, and the development of a large quantity of intestinal gases smelling of sulphuretted hydrogen. Hermann Hoffmann—*Zur Verdauungslehre*, Hæser's Archiv, Bd. VI, (1844,) S. 177—quotes the views of these authors with approval, and treats at some length of the antiseptic influence of the bile. Bidder and Schmidt—*Die Verdauungssäfte und der Stoffwechsel*, Mitau and Leipzig, 1852, p. 218—in the case of dogs in which they had established biliary fistulæ, observed similar conditions to those noted by Tiedemann and Gmelin after ligation of the bile-duct. Not merely did the fæces of such dogs possess an almost carrion-like odor, but the dogs were troubled with continual borborygmus and the escape of very offensive flatus. These conditions, however, were only observed when the dogs were fed on animal food, and were most marked when they were fed on flesh alone. When the same dogs were fed on bread only, they were troubled quite as much by wind, but both the flatus and the fæces were nearly odorless, and the latter were even more strongly acid than in dogs without biliary fistulæ when fed on the same diet. Th. Schwann—*Expériences pour constater si la bile joue dans l'économie animale un rôle essentiel pour la vie*, Nouveaux Mémoires de l'Academie Royale des Sciences et Belles-lettres de Bruxelles, Tome XVIII, (1845,)—who was the first to establish biliary fistulæ in dogs, does not mention whether the stools of the animals on which he operated became fetid or not; while N. Blondlot—*Essai sur les Fonctions du Foie et de ses Annexes*, Paris, 1846—succeeded in establishing a biliary fistula in a bitch, whose fæces after the operation, he declares, were neither more nor less odorous than those of healthy dogs; and on this account he denies the antiseptic action of the bile, (p. 71.) It appears, however, from a subsequent paper by the same author—*Inutilité de la Bile dans la Digestion proprement dite*, Paris, 1851—that this bitch lived in good health for five years after the operation with the fistula still open, whence Austin Flint, Jr.—*The Physiology of Man: Alimentation, &c.*, New York, 1867, p. 362—argues with great plausibility that Blondlot's experiment must have been incomplete, and that, in spite of the operation, a communication must have continued to exist between the bile-duct and the duodenum through which a portion of the bile must have found its way into the intestine. Dr. Flint himself found the stools of a dog in which he successfully established a biliary fistula extremely offensive. (*Op. cit.*, p. 369.)

animal is fed partly or entirely on flesh. According to Bidder and Schmidt, if such dogs are fed exclusively on bread the putrid decomposition does not take place, but the stools are preternaturally acid; and it is stated by Longet* that the lactic acid developed in the alimentary canal during the decomposition of vegetable food exercises an antiseptic action similar to that of the bile. After the fæces are voided the antiseptic influence of these substances continues to act, and this is no doubt the reason that decomposition does not occur more rapidly than it does.

That the fluid stools of diarrhœa putrefy as rapidly as they do is owing in part to the fact that they contain a much greater proportion of water than the normal fæces, which is of course favorable to the occurrence of speedy decomposition; in part it is due, in many cases at least, to the circumstance that the bile is diminished in quantity, as indicated by the pale color of the dejecta, and that its antiseptic influence is proportionately diminished. These two factors appear to be sufficient to account for the phenomena in most cases. It is indeed probable enough that the morbid secretions of the inflamed mucous membrane of the intestine may contain organic matters in a more unstable state of equilibrium, and therefore more prone to decompose than the normal intestinal juices, but if this should be shown to be true, it would rather afford a simple chemical explanation of the speedy decomposition than favor the supposition of Dr. Inman.

Putrid stools much more frequently attracted attention in dysentery than in acute diarrhœa, and in that case yet another factor, namely, the necrosis of the diphtheritic sloughs, often enters into the question of causation, as will be shown hereafter.

The stools vary as much in their *frequency* as in other particulars. There may be but two or three loose passages daily, or the number may be as great as twenty, fifty, or even a hundred, or more, in the twenty-four hours. The *quantity* of the dejecta is also very variable, and stands in no direct relationship to the frequency of the motions. It is almost always greater than the normal quantity, which may be estimated as, on an average, about five ounces.† According to Dalmas the liquid stools may amount, in extreme cases, to as much as forty pounds in the twenty-four hours.‡ It has been shown by Ihring§ that this increase in quantity is not due merely to an increase in the quantity of water contained in the stools, but that the absolute amount of solids excreted is also increased.

Occurrence of similar cases in groups.—A noteworthy fact, observed during the Civil War, which deserves remark in this place, was the tendency of the cases of acute diarrhœa, occurring in any particular command at a given time, to present a number of phenomena in common, resembling each other both in the grade of the attack, the constitutional condition of the patients, and the concomitant complications. Nor is this circumstance surprising, since large bodies of men were exposed simultaneously to similar morbific influences. Various grades of the disorder thus became epidemic, from simple looseness without pain, to the severest inflammatory forms, with divers coexisting constitutional disturbances, especially those resulting from the malarial influence, the scorbutic taint, or both.

As an example of the milder epidemics, I may refer to those outbreaks which so frequently occurred, especially during the first year of the war, immediately after bodies

---

* *Traité de Physiologie*, Tome 1, Paris, 1861, p. 250.

† According to WEISARG, 4. 6 ounces; according to HAMMOND, 5. 24. See AUSTIN FLINT, Jr. *The Physiology of Man: Alimentation, &c.*, New York, 1867, p. 395. LEHMANN estimates the quantity at 120 to 180 grammes—*Physiological Chemistry*, translated by G. E. Day, London, 1853, Vol. II, p. 141. CARPENTER puts it at from 2 to 10 ounces—*Principles of Human Physiology*, London, 1869, p. 149. SMITH and MILNER found the average weight of the fæces in the case of prisoners at Coldbath Fields Prison, condemned to treadwheel labor, and fed on a full diet with brown bread, to be 8. 55 ounces, which they estimate as "double of that found in ordinary life."—*Year-Book of the New Sydenham Society* for 1861, p. 83.

‡ *Dict. de Méd.*, 2me édit, Tome X, Paris, 1835, p. 271. § Thesis cited on page 278, *supra*.

of recruits were first assembled in camps and barracks.* Regiments encamped in tents in healthy localities appear to have suffered, as well as those in which the men were huddled together in ill-ventilated temporary quarters in cities and towns, or crowded into wooden barracks left filthy by their former occupants. The extreme frequency of such outbreaks is indicated by the fact that the ratio of the cases of acute diarrhœa to strength among the white troops was larger during the summer of 1861, at the very commencement of the war, than at any subsequent period, and the mild character of the disease is shown by the proportionately small mortality during the same period. Among the colored troops in the Atlantic region the same circumstance is noticeable during the first summer represented by the reports. In the Central region, however, the diarrhœa which prevailed among the new levies of colored troops was, in consequence of the circumstances alluded to on page 8, of a much more fatal character.

In these initial epidemics the type of the disease most frequently observed was a simple painless flux, with copious, often watery passages, and accompanied by comparatively little constitutional disturbance. The great majority of such cases recovered in a few days. A certain proportion of severer cases often occurred, however, and mild dysenteric attacks frequently coexisted.

Sometimes a newly levied regiment escaped until after it left its native State and went into its first encampment at or near the seat of war; and, under the same circumstances, second outbreaks were common enough among regiments which had already suffered before leaving home. Such outbreaks also were usually mild, the great majority of the patients speedily recovering.

At a later period in the war, after the troops had been long exposed to the deleterious influences of camp life, the cases of diarrhœa assumed a more serious character, were apt to pursue a more protracted course, and exhibited a greater tendency to pass into the chronic form.

Coexistence of other diseases with diarrhœa.—Moreover, the character of the diarrhœa which prevailed in a command at any given time was very often more or less modified by the simultaneous prevalence of certain other affections, especially of dysentery, cholera morbus, intermittent and continued fevers, and scurvy, or its milder manifestation the scorbutic taint. The operation of the causes which produce these affections at the same time with those which produce diarrhœa not merely led to the occurrence of cases of the several disorders named, some of which affected those who were already laboring under diarrhœa, but often modified, more or less profoundly, the constitutional condition of even those diarrhœal patients who escaped the actual development of the second disease. A few words may here be said with regard to those affections whose coexistence with diarrhœa

* In addition to the few references to this subject in the reports in Section II, I note two interesting communications in the Boston Medical and Surgical Journal, Vol. LXV, 1861, pp. 204 and 316—the first by Surgeon GEORGE A. OTIS, 27th Massachusetts volunteers, (subsequently Assistant Surgeon U. S. A., and editor of the Surgical Volumes of this work,) who comments on the prevalence of diarrhœa in his regiment, then just assembled in camp at Springfield, Massachusetts, and expresses the opinion that those of the men who were unprovided with flannel under-garments were most liable to the disease: "In company F, Westfield, 100 strong, scarcely a man escaped. I attributed this to the delay in mustering in this company, and procuring suitable under-garments from the quartermaster." The second communication is by Surgeon JAMES BRYAN, Cameron dragoons, who, writing from the Army of the Potomac, November 6, 1861, gives a brief description of a form of diarrhœa which was common enough among the recently enlisted troops: "This disease, as has been already stated, is generally preceded by several days' constipation of the bowels, and in the recently enlisted volunteer is usually of a mild character. Pain in the region of the stomach and umbilicus gradually extends down to the colon and rectum. The discharges, at first more or less solid, become afterwards fluid, mucoid, watery or bilious, accompanied not unfrequently with considerable tenesmus. The abdominal pains cease with the occurrence of tenesmus, and this again terminates perhaps at the end of two or three days from the onset of the disease. The patient is thus restored to health without medical interference, for the time being." See, also, on the same subject, JOHN C. DRAPER, *Medical Experience at Harper's Ferry during a three months' campaign*—The American Medical Times, Vol. V, 1863, p. 325, and a letter from Ship Island, Mississippi, by Surgeon J. H. THOMPSON, 12th Maine volunteers, in the Boston Medical and Surgical Journal, Vol. LXVI, 1862, p. 338: "On the second day after our debarkation, twenty-four privates and officers were attacked with diarrhœa and dysentery, and so rapidly the epidemic diffused itself that nearly every man in the command was affected with it during the following three weeks."

most frequently attracted attention. Of these the most intimately allied to diarrhœa is *dysentery*. A certain proportion of cases of dysentery always occurred whenever acute diarrhœa was present. Not only is this circumstance referred to in many of the reports in Section II,* but, as will be shown hereafter, the ratio of cases of acute dysentery reported increased and diminished, as a rule, with the ratio of cases of acute diarrhœa, though not always in exactly the same proportion. A portion of these cases of acute dysentery occurred *de novo* in subjects who had previously enjoyed good health, but very often the dysenteric attacks supervened upon acute diarrhœas which had resisted treatment, or selected as victims those who were already suffering from a chronic flux. This circumstance will be again referred to in the course of the remarks on dysentery; at present, however, it may be suggested, that when it is remembered that the colon is usually involved in acute diarrhœa, it will readily be understood that a very slight extension of the inflammation downwards will involve the rectum and bring on dysenteric symptoms. This appears to take place quite frequently in the more severe cases, so that in fact simple inflammatory dysentery seems to differ from inflammatory diarrhœa chiefly in the intensity of the morbid process, both diseases occurring under similar circumstances and apparently under the influence of identical causes. As to the more dangerous diphtheritic form of dysentery, though the relationship is not so clear, there can be no doubt that it is more apt to occur in those whose intestinal mucous membrane is already the seat of a simple inflammatory process than in perfectly healthy individuals.

It has already been mentioned that nausea and vomiting frequently occur as symptoms of acute diarrhœa. Sudden attacks of simultaneous vomiting and purging, due often to mere irritation of the gastro-intestinal mucous membrane, sometimes, however, to inflammation of various grades, were very generally reported under the head of *cholera morbus*. The number of cases ascribed to this disease was 25,215 among the white troops, with 275 deaths, and 1,151 among the colored troops, with 30 deaths.† These were reported at all seasons of the year, but were most numerous from May to October; there does not, however, appear to be any very close connection between the fluctuations in their monthly ratios and those of diarrhœa or dysentery.

The simultaneous prevalence of diarrhœa with *intermittent* and *remittent fevers* is alluded to in a number of the reports,‡ and the monthly ratios of these fevers, to be presented hereafter, will indicate considerable similarity between their general distribution and that of diarrhœa, both as regards season and region. It was also exceedingly common for intermittent or remittent fever to coexist with diarrhœa in the same individual, the fever sometimes preceding and sometimes following the initiation of the bowel affection. Moreover, diarrhœa was of very frequent occurrence among those who gave evidence of chronic malarial poisoning by their yellowish, pallid countenances, more or less pronounced emaciation, and enlarged spleens.

Note also the remarks of T. H. WALKER—*Camp Diarrhœa*, in the Chicago Medical Journal, Vol. XIX, (1862,) p. 478—on the frequency with which diarrhœa was complicated with intermittent fever in the army before Corinth, Mississippi.

The coexistence of diarrhœa with *continued fevers* also attracted attention.* It is well known that in ordinary typhoid fever diarrhœa is a prominent symptom, and it will be shown in a subsequent chapter that it frequently occurred also as a complication of a form of continued fever which differed from typhoid fever in the absence of the characteristic lesion of the patches of Peyer as well as in other particulars. Of course, therefore, it will be understood that patients were often supposed at first to be ill with simple diarrhœa who ultimately proved to be in fact suffering from some form of continued fever; but it is also true that continued fevers and diarrhœas frequently prevailed together, affecting different individuals in the same command.

The coexistence of diarrhœa with openly pronounced *scurvy* was not very common, since the latter affection fortunately proved comparatively rare. A recognizable, but usually mild, *scorbutic taint* was of more frequent occurrence, and whenever this made its appearance diarrhœa became prevalent, and showed an increased tendency to pass into dysentery and to become chronic. It not unfrequently happened that the scorbutic taint coexisted with chronic malarial poisoning, and that numerous cases of diarrhœa, dysentery, ague and continued fever occurred simultaneously in the same command. Under such circumstances all the patients usually presented many symptoms in common and it was not always easy to make an accurate diagnosis.†

The occasional coexistence of diarrhœa with *inflammatory affections of the respiratory organs* is also alluded to in several of the reports,‡ and deserves some mention in this place. It was noticed, especially after the occurrence of epidemic measles, and after exposure to cold and inclement weather, particularly after marches during which the troops were insufficiently sheltered at night. Under such circumstances numerous cases of diarrhœa and dysentery occurred along with cases of bronchitis or even of pneumonia. For example, during the siege of Fort Donelson in February, 1862, the besiegers were exposed without shelter, and even without fires at night, to a light fall of snow degenerating into sleet; as a consequence, "diarrhœa, dysentery and pneumonia of a typhoid type became fearfully prevalent."§

Under such circumstances the chest and bowel affections sometimes coexisted in the same individuals; but perhaps it more frequently happened, that while some suffered only from the former, in others the latter was the sole complaint. The development of the one disease or of the other, under such circumstances, was probably very often dependent upon the previous history of the patient; those who had already frequently suffered from diarrhœa being most apt to be attacked by bowel affections after such exposure, while those who had previously been troubled with coughs and colds were most apt to contract chest affections.

---

* On the association of diarrhœa with continued fevers, note in Section II the remarks of MARSH, p. 68, STUART, p. 69, PERRY, p. 70, WOOD, p. 74, MCKELWAY, p. 75, BLAKESLEE, p. 76, CADY, p. 77, FORBES, p. 82, WALTON, p. 88, MILLER, p. 89, and ANGELL, p. 97.

† Note, for example, as affording a lively picture of this difficulty, the remarks of Surgeon ALONZO J. PHELPS, U. S. V.—*Observations in the Field, near Corinth, Mississippi*, American Medical Monthly, Vol. XVIII, August, 1862, p. 94.—Speaking of one of the hospitals left when the western armies advanced after the evacuation of Corinth, he says: "In this hospital alone, there were registered seventeen hundred patients. All of these cases presented the same type of disease, but variously expressed under the terms of Febris Typhoides, Diarrhœa, Dysentery, Scorbutus and Debilitas. Subsequent observation demonstrated the artificial character of this classification, and that the disease acquired its name from the most prominent symptoms present, and not in accordance with reliable pathological conditions. It could not easily have been otherwise, as all surgeons will testify who have found upon their register in the course of a few weeks the same person under treatment for dysentery, diarrhœa and febris typhoides; the same attack acquiring a new name, in accordance with the development of new symptoms, or the absence of others. In fact, there has been so great a variety in the manifestation of these diseases, seldom ever running a regular course, but alternating one with the other, and exhibiting so many symptoms in common, that the nomenclature could not have been otherwise than very confused."

‡ See, for example, in Section II, the remarks of BELLOWS, p. 69, LEE, p. 71, TIBBALS and WOOD, p. 74, HOYT, p. 80, HOOD, p. 83, and MILLER, p. 89.

§ See the report of Surgeon JOHN H. BRINTON, U. S. V.—Appendix to Part I, p. 28. See also, in the same Appendix, the remarks of W. R. DE WITT, Jr., p. 213, HATCHITT, p. 250, and COOPER, p. 325, as furnishing other examples.

PROGRESS AND TERMINATION.—It has been shown in the first section of this chapter that the number of deaths attributed to this cause was but one to every three hundred and ninety-five cases among the white troops, and one to eighty-three cases among the colored troops. The danger of the disease did not, then, consist in the immediate probability of a fatal issue, but in its proneness to pass into dysentery or to become chronic, and in the fact that even when it apparently terminated in complete recovery the soldier was usually left peculiarly liable to subsequent attacks.

The majority of cases terminated in recovery in the course of a few days; but often, even when the diarrhœa was mild, comparatively painless, and unaccompanied by fever, it was of longer duration, sometimes persisting, in spite of treatment, for weeks together with variable results. Painless diarrhœas were often neglected by the patients for some time, and it was not uncommon for soldiers to present themselves at sick-call for the treatment of a flux which, on inquiry, they confessed had already lasted several weeks. Such cases were apt, sooner or later, to assume a graver character; not unfrequently fever set in more or less abruptly, the stools became more frequent and painful, and a certain degree of abdominal tenderness was developed; in some instances the diarrhœa passed into dysentery; in others it passed gradually into some form of chronic flux.

Those cases which, from the very first, were accompanied by marked fever and more or less abdominal tenderness, very often lasted ten days or two weeks before convalescence set in; occasionally, especially in the fatal cases, they were still more protracted, three or four weeks, or even longer, sometimes elapsing between the inception of the disease and the fatal issue. Both in these cases and in those in which the febrile reaction was not developed until the diarrhœa had already lasted some days, the fever was sometimes distinctly remittent in its character, assuming the quotidian or tertian type, and presenting a train of symptoms not unlike those of malarial remittent fever. This resemblance was occasionally still further increased by the appearance of an icteroid hue of countenance, or of decided jaundice, a complication which occurred most frequently in those cases in which there was much nausea and vomiting. Such cases were doubtless, in part at least, actual remittent fevers accompanied by catarrhal inflammation of the intestinal mucous membrane, and readily explained by the circumstance that the causes of the two diseases acted simultaneously upon the same individuals. In yet other cases the fever was of a continued type, and this circumstance, taken in connection with the tympanites and tenderness in the right iliac region which at times accompanied the diarrhœa, produced in some instances a misleading resemblance to ordinary typhoid fever. In all these febrile cases the fever was usually of an adynamic character from the very first, and the rapidity with which the patients became emaciated was a noteworthy circumstance.

In fatal cases the pulse became progressively more frequent and feeble; the tongue, which at first had been furred and moist, became red and dry; the abdomen greatly distended with flatus; the stools more frequent, often acquired a very offensive odor, finally were passed involuntarily, and the patient gradually sank. Sometimes delirium set in toward the close, or the patient passed into a state of stupor and died comatose; more frequently the mind remained clear almost to the very last. In other cases some intrathoracic inflammation, especially a low form of pneumonia, was developed a few days before death, and was the immediate cause of the fatal issue. In others, marked symptoms of local, or even of general peritonitis, were recognized before death.

In the more favorable cases the fever gradually subsided, the pulse became slower and stronger, the stools diminished in frequency, acquired a more natural character, and the appetite and strength gradually returned. Very often, however, several months elapsed before the patient was fully restored to health. Moreover, in a considerable number of instances, after the subsidence of the fever the diarrhœa continued with more or less severity, either continuously or at intervals, and finally assumed the characters of the chronic forms of flux. This was the history of many of the cases of diarrhœa which occurred in the Army of the Potomac during the summer of 1862. The designation Chickahominy diarrhœa, derived from the stream along whose swampy banks the Army of the Potomac was encamped during the latter part of May and the month of June, was very generally bestowed upon all the cases of flux sent to General Hospital from that army during this period and the subsequent encampment at Harrison's Landing. As thus used the term embraced several forms of diarrhœa and dysentery, all of which, however, occurred also in other armies and at various periods of the war.

INFLUENCE OF SEASON AND REGION.—The number of cases of acute diarrhœa, and the mortality attributed to this disease in the reports, were discussed in the first section of this chapter; but, in addition to what was then said, I have deemed it advisable to add in this place a table showing the monthly ratio to strength of the cases reported in each region under this head.

Number of cases taken on sick report each month with Acute Diarrhœa among the White troops, expressed in ratio per 1,000 *of mean strength.*

The ratios in the foregoing tables, like those of the tables representing the number of cases of diarrhœa and dysentery given in Section I,* are deduced from the number reported as taken on sick report monthly; and, therefore, do not represent the whole number sick with diarrhœa, but simply the new cases. The ratios for the several years are not the sums of the monthly ratios, but are directly computed from the annual mean strength and the total number of cases. A series of curves constructed from the ratios given in these tables would be found to be very nearly parallel to those of the diagrams in Section I, which represent the total number of acute and chronic cases of both diarrhœa and dysentery. The parallelism exists in the case of the colored troops as well as the white, and in all three regions, though, as might be expected, it is least exact in the Pacific Region, where the number of cases is the smallest.

* Pages 19 and 23 *supra.*

Post mortem Appearances in Acute Diarrhœa.—A large proportion of the deaths from acute diarrhœa occurred in the field,* where there were no facilities for making post mortem examinations, and hence the number of autopsies reported in cases which terminated fatally in the early stages is not so large as could be wished, even if we include intercurrent diarrhœas, which set in shortly before the fatal issue, in patients dying of other diseases. A much larger number of autopsies was reported in cases which had lasted from three or four weeks to two months, or even longer, both because cases of this class were so much more numerous, and because they so much more frequently found their way to the general hospitals, where the opportunities for making autopsies were comparatively good. These more protracted cases pass by insensible degrees into those which may properly be called chronic, and it is difficult to draw a boundary line between the two groups. For this reason I have thought it advisable to present in this place all that I shall have to say with regard to the anatomical details of hyperæmia of the intestinal mucous membrane, and those cases of inflammation which do not progress so far as to develop intestinal ulcers, reserving all consideration of the ulcerative process until I come to consider the chronic forms of intestinal fluxes.†

It must, however, be distinctly understood that this arrangement is only made to avoid needless repetitions; for the rapidity with which ulcers are developed varies with the intensity of the disease, so that on the one hand they may be encountered in patients who have been ill but a short time,‡ while on the other hand it is not uncommon to meet fatal cases in which no intestinal ulcers exist, although the flux has been protracted for from five or six months to a year, or even longer.

It is further to be remarked that the lesions about to be described differ in no essential

---

* Viz: 1,407, or nearly one-half the number of deaths reported under this head.

† Although it was well known to the ancients that a protracted diarrhœa might give rise to inflammation, and ultimately to ulceration of the intestines, (*i. e.*, pass into dysentery,) yet this flux was rather regarded as a merely functional disturbance, and a knowledge of the fact that some degree of simple inflammation of the intestinal mucous membrane is usually present in diarrhœa is of comparatively recent date. According to Craigie [p. 688, *op. cit.*, *infra*] "distinct traces of the opinion, that intestinal inflammation gives rise to diarrhœa," may be found in the Reports of Ludovic Bang—*Selecta diarii nosocomii regii Fridericiani Hafniensis*, Hafniæ, 1789—but I understand that physician to speak of it rather as an occasional than as a usual cause. Thus, in November, 1782, (T. I, p. 47,) he records a case of diarrhœa in which intestinal inflammation being suspected, (aliqualem inflammatorium statum intestinis inhærere suspicans,) blood was let three times, and the patient cured. In August, 1786, (T. II, p. 233,) having opened the body of a subject in whom a painful diarrhœa had been followed by peritoneal effusion, for which paracentesis had been employed with only temporary relief, he found the omentum thickened and adherent to the mesocolon, and explained this condition by supposing a transfer of inflammation to have taken place from the intestines. He imagines a similar transfer of inflammation to explain the generation of the purulent fluid found in the abdominal cavity of a woman dead of a painful diarrhœa, in April, 1787, (T. II, p. 314,) but it is worthy of note that he did not record that he actually observed any intestinal inflammation in either of these cases. The modern view of the relation of intestinal inflammation to diarrhœa seems first to have been suggested, as a conjecture, by J. Carmichael Smyth—*Of the different kinds or species of Inflammation*, [read January 8, 1788,] Med. Communications, London, Vol. II, 1790, p. 168—who remarked, in his sketch "of the inflammation of mucous or pituitous membranes:" "I think it also probable, (for we can have no positive evidence of the fact,) that in diarrhœas, from catching cold, the villous or interior coat of the stomach and intestines is sometimes slightly inflamed," (p. 210.) He pointed out the similarity in the general characters of the inflammations of the Schneiderian, the pulmonary and the gastro-intestinal mucous membrane, as well as the difference in symptoms belonging to each, and observed: "Thus, what occasions sneezing in one place excites coughing in another, and purging in a third." Compare with these utterances the remarks made a few years later, on "diarrhée catarrhale," by Pinel—*Nosographie Philosophique* [1798]—I cite 6me éd., Paris, 1818, T. II, p. 316. Matt. Baillie, in his *Dissections*—I cite Wardrop's edition of his works, London, 1825, Vol. I, p. 210—remarked: "It does not always happen, when a person has died from purging, that there are ulcers in the intestines. In two cases, which I have opened, of persons who died from this complaint, the small intestines were inflamed, so as to preserve the appearance of distinct vessels, the small branches of arteries curling most beautifully on the outer surface of the intestine filled with florid blood, and the villous coat being slightly red. The great intestine was contracted, especially towards the rectum, and filled only with mucus, there being at the same time no inflammation in it." For an account of the modern views with regard to the conditions referred to the reader may consult, besides the works mentioned in the first note on page 266 *supra*, the following: Broussais—*Hist. des Phlegmasies*, 3me éd., Paris, 1822, T. II, p. 517 *et seq.*; C. Billard, *De la Membrane Muqueuse Gastro-intestinale*, Paris, 1825, p. 126; David Craigie, *Elements of General and Pathological Anatomy*, Edinburgh, 1828, p. 688; G. Andral, *Précis d'Anatomie Pathologique*, Brussels, 1837, Tome I, p. 343; Carl E. Bock, *Lehrbuch der pathologischen Anatomie*, 2te Aufl., Leipzig, 1849, S. 328; also 4te Aufl., 1864, S. 430; August Foerster, *Handbuch der speciellen pathologischen Anatomie*, Leipzig, 1854, S. 65; also 7te Aufl., 1864, S. 206; Samuel Wilks, *Lectures on Pathological Anatomy*, London, 1859, p. 295; also 2d ed. Lloyd—*Special report of an outbreak of jail diarrhœa, assuming a choleraic form, in the district jail of Nellore, during the months of September and October*, 1866, The Madras Quarterly Journal of Medical Science, January, 1867, p. 17—for an interesting account of the pathological appearances in a number of cases of acute diarrhœa terminating fatally after a few days' illness.

‡ Case 402 may be cited as an illustration of the early development of intestinal ulcers. This man died about two weeks after he was first taken sick with acute diarrhœa, and irritability of the stomach was a marked feature in his case. The diagnosis recorded is acute gastro-enteritis—"The lower two feet of the ileum and the whole of the large intestine were studded thickly with small recent ulcers, very few exceeding a pin's head in size."

particular from those observed in certain mild cases of dysentery. It also frequently happens in diphtheritic dysentery, with intense pseudomembranous inflammation of the large intestine, that the small intestine presents lesions identical with those which are now to be considered. Moreover, the inflammation of the mucous membrane of the large intestine, and of the small intestine between the thickened patches of Peyer, which is of constant occurrence in typhoid fever, differs anatomically in nothing from the inflammation observed in acute diarrhœa. It must be understood, therefore, that many cases of dysentery and fever furnish additional material for the study of simple inflammation of the intestinal mucous membrane, and that much of the description about to be presented applies also to these diseases, as will be more fully explained hereafter in connection with each.

The fragmentary and imperfect character of many of the autopsies included in the foregoing section has already been alluded to, and the reasons which induced the preservation in this work of so many incomplete observations have been briefly indicated.* The imperfection in the record then alluded to is particularly felt when the attempt is made to classify the autopsies so as to select those which may be used for the purposes of the present inquiry. It is, of course, not surprising that in many of the fatal cases no autopsy was made; and some of these have been selected for publication, as, for example, cases 44, 51, 56, 59, 76, 77, 95 and 861. Nor is it remarkable that among the cases in which autopsies were made, there should have been some in which the abdominal viscera were so glued together by chronic peritonitis that it was not found convenient to examine the intestinal mucous membrane, as happened in cases 600, 657, 666, 729 and also in 667, in which last case it is recorded merely that "the intestines themselves were green and rotten," probably from post mortem changes. But it must certainly seem strange that autopsies should have been made, in cases in which the patient was known to have suffered from diarrhœa or dysentery, without examining the intestinal mucous membrane, or at least without recording the conditions observed. This was actually done in quite a number of instances, the attention of the officers by whom the examination was conducted appearing to have been arrested by some intercurrent lesion which was, or was supposed to be, the immediate cause of death. As examples of this oversight in cases of acute diarrhœa I may mention case 424, in which the patient died of diphtheria forty days after he was first taken on sick report for diarrhœa, and case 535, in which death took place from erysipelas and pneumonia nine days after admission from regimental hospital. As instances of the same oversight in sub-acute and chronic cases, the following may be cited: Case 104, the patient suffered also from albuminuria, and empyema was the immediate cause of death. Cases 181 and 188, death took place from pneumonia; supervening in case 181 upon tubercles of the lung. Case 190, the patient had also suffered from fistula in ano; death took place from phthisis. Case 245, the patient died of peritonitis; the surface of the abdominal viscera was spotted with coagulable lymph. Case 251, death from scurvy. Case 404, death from convulsions; a tiny abscess was found in the left hemisphere of the brain, and the lower and posterior portions of the right lung were in the stage of gray hepatization. Case 570, death from diphtheria. Case 586, the patient had received a blow in the epigastrium, and suffered from nausea and vomiting, with diarrhœa at intervals; "the diarrhœa gradually grew worse" until death; on the autopsy pseudomembranous inflammation of the stomach was found, but nothing is said of the condition of the rest of the alimentary canal. Case

* *Supra*, p. 102.

612, the patient died suddenly, and the attention of the officer who made the autopsy appears to have been diverted from the intestinal canal by a heart-clot, which he imagined to have been the cause of death. Case 683, death was caused by strangulation of a portion of the ileum, which had passed through an opening in the mesentery. Case 702, death was apparently due to valvular disease of the heart. Case 711, the patient died of œdema of the epiglottis. Case 770, death from meningitis; the patient had also tubercular disease of the lungs. Case 818, death from gastritis.

To the foregoing I may add two cases in which it is explicitly recorded that the small intestine was healthy, but in which no examination of the large intestine was made, or, at least, if this portion of the alimentary canal were inspected, it was not thought worth while to record the appearances observed, the medical officer making the autopsy being probably of the common opinion already alluded to,* that the lesions of diarrhœa are to be sought chiefly in the small intestine. One of these, case 390, was an example of acute diarrhœa, accompanied by vomiting, frequent pulse and rheumatic pains, in which the patient was apparently convalescent after a four weeks' illness, but had a relapse and died of facial erysipelas. The other, case 180, was an example of chronic flux in a patient who suffered also from dropsy, and who appears to have died of bronchitis and congestion of the brain.

There are, besides, several cases in which it is true the intestines were examined, but in which the medical officer, having taken care to record that "no ulceration was found in any part of the intestinal mucous membrane," or that "no intestinal ulceration was detected," did not think it worth while to add any further remark, so that the actual condition of the intestinal mucous membrane must remain a matter of conjecture. I cite, as examples, one sub-acute case, No. 539, in which, after a few weeks' illness, the patient was apparently convalescent, but had a relapse and died, probably from the diarrhœa rather than from any intercurrent affection; and several chronic cases, viz: Case 252, a paroled prisoner of war, who reached the hospital in a deplorable condition, and in whom the immediate cause of death was pneumonia; case 540, in which the patient succumbed to dropsy of the pericardium, and case 582, in which the cause of death was œdema of the lungs. I may add to this series of imperfect observations case 633, in which it is merely recorded that "some congestion of the abdominal viscera was found," without stating whether the intestinal mucous membrane was examined or not.

It would hardly seem likely that acute diarrhœa could exist with such intensity as to cause death, without producing any lesion of the intestinal canal of sufficient gravity to be recognized on the autopsy, still less that this could happen in chronic cases. It does not, however, appear improbable that if death should take place from some other disease in patients suffering from a mere diarrhœa of irritation, in whom at most a certain degree of hyperæmia of the mucous membrane was the only lesion, it might sometimes happen that the congested vessels might contract sufficiently during the death agony to expel the greater part of the contained blood, and that nothing abnormal should be detected in the intestinal canal even by the most practiced eye.† I am not, therefore, disposed to discredit

* *Supra*, p. 266.

† RILLIET et BARTHEZ—*Traité clinique et pratique des Maladies des Enfants*, Paris, 1843, Tome I, p. 491—found the intestinal tube in a perfect state of integrity in one of every twelve infants in whom a more or less abundant diarrhœa had preceded death—a result deduced from the comparison of nearly three hundred autopsies.—NIEMEYER—*Lehrbuch der speciellen Pathologie und Therapie*, 7te Auflage, Berlin, 1868, Bd. I, S. 623—states that on the post mortem examination of children dead of chronic diarrhœa it is common to find nothing but the *easily-overlooked* residua of chronic intestinal catarrh. The same author has also pointed out (*loc. cit.*, p. 617) that in the intestinal catarrh of adults it sometimes happens that the injection disappears completely, leaving the mucous membrane pale and bloodless.

all the instances contained in the last section in which it is recorded that the intestinal canal was healthy, or that no lesion could be discovered, although doubtless in some cases the medical officers by whom the examinations were made could hardly be regarded as experts, and in others there is no evidence that the patient actually had diarrhœa except the entry on the hospital register, which may not always have been accurate.

I note in all twenty cases belonging to the category under consideration, in ten of which no further evidence exists that the patient really suffered from diarrhœa than that just alluded to. Three of these cases, 125, 127 and 129, belong to the careful series of autopsies reported by Professor Joseph Leidy, of the University of Pennsylvania; all the patients were admitted August 10, 1862, from the Army of the Potomac, then at Harrison's Landing, Virginia. Case 125 died the day after admission, from pleuro-pneumonia. In the two other cases the cause of death was not determined. Case 127 died three days after admission; "the thoracic and abdominal vicera exhibited no perceptible lesions." Case 129 died two days later, "apparently of debility." "No anatomical lesion was discoverable in any of the thoracic or abdominal viscera." I incline to the supposition that the last two cases were really deaths from scurvy. In two of the remaining cases the diagnosis recorded on the register is simply "diarrhœa." In case 485, the patient died eleven days after admission, of congestion of the lungs; "nothing else abnormal was observed." In case 584, "no evidences of disease were recognized in the intestinal canal; and, in fact, nothing was discovered during the autopsy which could satisfactorily account for the fatal result," resembling in this respect the two cases of Dr. Leidy, just mentioned. In the other five cases the diagnosis recorded on the hospital register was "chronic diarrhœa." In case 462, the patient died a week after admission from his regiment, of meningitis and pneumonia. In case 774 death was caused by empyema. In cases 795 and 822 the cause of death was pneumonia, and in the latter instance a number of small abscesses were found in the liver. In case 829 the cause of death was phthisis.

But, besides the ten cases just considered, there are ten others in which no lesion of the intestinal canal could be found, although, from the symptoms recorded, or from the fact that the patient passed through several hospitals, in all of which he was registered as suffering from diarrhœa, no reasonable doubt can exist that he really was affected with that disease. One of these, case 321, was apparently an example of the acute form of the disease complicating an attack of pneumonia; the patient died, two days after admission from his regiment, of the latter disease. While in hospital he had watery, offensive stools, but "nothing abnormal was observed in any portion of the intestinal canal." Another, case 438, was recorded on the hospital register simply as "diarrhœa." The patient said "he had suffered from diarrhœa for some time," and died of pneumonia four days after admission from the field hospital; "no disease was detected in the stomach or bowels." The remaining eight cases were recorded on the hospital register as "chronic diarrhœa," and in each of them there appears to be collateral evidence that the disease was correctly named. Case 110 died of pleuropneumonia after having suffered from chronic diarrhœa, according to the record, for more than nine months. Case 187 is reported to have had scurvy as well as diarrhœa; the cause of death was a hæmorrhage into the right pleural sac, the source of which was not made out. Case 235 was also complicated with scurvy; the passages are reported to have been "numerous, bloody, and attended with tenesmus," representing dysentery rather than diarrhœa; general venous congestion was observed

after death; "the blood was dark and not coagulated in the heart," but "nothing was found in the organs to explain the cause of death." Case 515 was complicated with insanity, and the cause of death was not satisfactorily made out. Case 606 died of phthisis; "the discharges from the bowels were frequent, watery, and very offensive;" "the mucous membrane of the stomach was thickened and congested," but "no intestinal lesions, such as would account for the diarrhœa, were recognized." Case 790 died of pneumonia. "He had frequent passages accompanied with pain and tenesmus;" "the mucous membrane of the stomach was inflamed," and there was an intussusception in the lower third of the ileum, but no other abnormity was observed in the intestinal canal. Case 793 died of pleuropneumonia; "nothing abnormal was detected in the abdominal viscera." Case 817 was one of Addison's disease; the patient had also "suffered from chronic diarrhœa for several months and was very much emaciated; the stools were frequent and watery," but the "intestinal canal presented no evidences of disease."

To the twenty cases just discussed, case 115 may, perhaps, be added; the patient had phthisis also, and died of hæmorrhage of the lungs; he appears on the registers of several hospitals as suffering from chronic diarrhœa, but "the stomach and intestines were nearly normal, the latter showing very little to account for the long-continued chronic diarrhœa from which the patient had suffered."

After excluding all such negative cases as those just referred to, there still remains a considerable number of autopsies in cases of acute, sub-acute, and even of chronic diarrhœa, in which the intestinal canal presented evidences of hyperæmia or catarrhal inflammation merely, without ulceration. Before attempting any analysis of these cases it will be convenient to present a sketch of the conditions observed.

Inflammation of the mucous and submucous coats of the intestines without ulceration.— In some of the fatal cases of acute diarrhœa the only intestinal lesion observable with the naked eye was a reddish discoloration of the mucous membrane, which, for the most part, occurred in patches of various dimensions from a few inches to several feet in length. Such patches were observed in all parts of the intestinal canal, but were more common in the ileum than in the jejunum, and were still more frequent in the colon, where they particularly affected the cæcum and sigmoid flexure. A continuous redness of the whole colon and of the lower part of the ileum was occasionally observed, but usually the patches were separated from each other by areas in which the mucous membrane appeared to be quite normal. The instances in which the small intestine alone was affected were very few, and probably even a part of these must be regarded as imperfect observations; those in which the large intestine alone was inflamed were common, and very often both were involved, the large intestine, however, being usually most extensively diseased.

The patches varied in color from pale pink to deep red or even livid purple. When portions of the gut were spread out over a white surface, or held between the eye and the light, arborescent figures, due to the distention of the small veins with blood, were generally conspicuous. Sometimes, also, small spots or blotches of irregular form and of a darker color than the rest of the patches were observed. Such small purpura-like blotches occasionally occurred also in the midst of apparently healthy portions of the mucous membrane. In some instances the reddened patches seemed to be quite normal in texture; in others the mucous membrane was more or less softened, so that it could readily be broken down and scraped off with the handle of the scalpel; occasionally it was œdematous. The dis-

eased mucous surface was generally coated with a glairy mucus, which was either quite colorless or of a yellowish, reddish, brownish or greenish hue, from the admixture of bile or blood; more rarely the surface was covered with a creamy muco-purulent coating. The peritoneal surface of the intestine corresponding to these reddish patches was generally quite normal, but sometimes in a condition of more or less pronounced hyperæmia, and occasionally thinly coated with a layer of opaque yellow lymph. Microscopical examination of these reddened patches showed their color to be due either to an engorgement of the small veins and capillaries with blood, to transudation of the coloring matter of the blood, to actual hæmorrhage into the mucous membrane and the sub-mucous layer, or to a combination of these conditions.

In the majority of cases the solitary follicles situated in the reddened patches were more or less enlarged; the most common condition, perhaps, being that in which they had attained the size of pin-heads, and appeared as whitish or yellowish elevations surrounded by a little circlet of increased vascularity. In the colon these minute elevations were generally sessile; in the small intestine they often had constricted necks, and projected from the surface of the mucous membrane like tiny polypi.*

Reddened patches, such as those above described, have been variously interpreted by the pathological anatomists. Regarded as evidences of inflammation by some, of congestion by others, they have also been looked upon as being mere post mortem alterations in very many cases at least. Lebert† has drawn attention to the circumstance that patches of venous or even capillary hyperæmia are met with in the bodies of subjects who have not suffered from any intestinal disease during life, and lays down the rule that unless, besides the redness, some alteration of texture, such as softening or induration, exists, or the coats of the intestine are thicker or thinner than normal, we should not admit the presence of inflammation. This rule must be accepted with a certain degree of reservation, so far, at least, as softening and abnormal thinness are concerned, for certainly the softening of the mucous membrane which takes place during commencing decomposition is even more

* I have searched for pictorial representations of simple acute and chronic non-ulcerative inflammation of the intestinal mucous membrane, as it occurs in diarrhœa, without finding much of interest. For representations of the redness and other changes of color, I may cite FERDINAND LESSER—*Die Entzündung und Verschwärung der Schleimhaut des Verdauungskanales*, Berlin, 1830, Tab. IV, Figs. 2 and 3; J. HOPE—*Principles and Illustrations of Morbid Anatomy*, London, 1834, Figs 116, 123, 124, 127, 128 and 129; ROBERT CARSWELL—*Illustrations of the Elementary Forms of Disease*, London, 1838, Inflammation, Plate II, Figs. 1, 2, 3 and 4; Melanoma, Plate III, Fig. 6. For illustrations of enlargement of the solitary glands, with or without pigment deposits, I may cite J. HOPE, *op. cit.*, Figs. 142, 143, 144 and 150; R. CARSWELL, *op. cit.*, Melanoma, Plate III, Fig. 5. In the same connection I may also refer to the remarkable etchings in the work of RŒDERER and WAGLER—*De Morbo Mucoso*, Gœttingen, 1762; and to the representations of enlarged solitary follicles in both small and large intestines of children dead of cholera infantum, by WM. E. HORNER—*Treatise on Pathological Anatomy*, Philadelphia, 1829, Plate III. See also a splendid colored plate in the work of H. LEBERT—*Traité d'Anat. Path.*, Paris, 1861, Tome II, p. 315, Plate CXXI, Figs. 1 and 2—representing a curious case of extreme hypertrophy of the villi just above the ileo-cæcal valve, in the case of a woman who died after suffering from diarrhœa several months, and in whom there were also numerous small follicular ulcers of the colon. On the other hand, the intestinal catarrh of Asiatic cholera has furnished a considerable number of excellent illustrations which represent a condition very similar to that observed in many cases of acute diarrhœa, and which may be advantageously compared with the illustrations about to be presented. Among the most noteworthy of these I may refer to J. CRUVEILHIER—*Anat. Pathologique du Corps Humain*, Paris, 1829–'35, Tome I, Liv. 14, Pl. 1–5; A. AUVERT—*Selecta Praxis Medico-chirurgicæ*, Paris, 1856, Tab. CV, CVI, CVII; H. LEBERT—*op. cit.*, Pl. CXV, CXVI and CXVII; J. F. H. ALBERS—*Atlas der Path. Anat.*, IV Abth., Bonn, 1862, Tab. XIII; also HAYDEN and CRUISE—*Report on Cholera*, (epidemic of 1866,) Dublin Quarterly Jour. of Med. Science, May, 1867, p. 345, (also reprint,) which contains three striking wood-cuts. I may also mention that the Museum contains three specimens of the small intestine from soldiers dead of Asiatic cholera, Nos. 883, 930 and 921, Medical Section, in which the anatomical conditions presented are strikingly similar to those shown in No. 600, which is represented in the photographic plate presented a little further on.

† H. LEBERT—*op. cit.*, Tome II, p. 201. The significance of redness and other discolorations of the intestinal mucous membrane has been the subject of a number of interesting inquiries. The view presented in the posthumous memoir of ROUSSEAU—*Des différens aspects que présente, dans l'état sain, la membrane muqueuse gastro-intestinale*, Archives Gén. de Méd., Tom. VI, (1824,) pp. 321 and 481—that any redness of the gastro-intestinal mucous membrane, whether slight or intense, depends upon congestion or inflammation; though it appeared to be substantially sustained by the observations of several independent inquirers, as, for example: WM. E. HORNER—*Inquiries into the healthy and diseased appearances of the Mucous Membrane of the Stomach and Intestines*, The American Journal of the Medical Sciences, Vol. I, 1827, p. 9, and A. MONRO—*The Morbid Anatomy of the Gullet, Stomach and Intestines*, 2d edit., Edinburgh, 1830, page 315—became untenable after it had been shown that redness might be induced by various post mortem changes. Consult on this subject the work of BILLARD—*De la Membrane Muqueuse Gastro-intestinale*, Paris, 1825, p. 256, and the convincing memoir of MM. RIGOT *et* TROUSSEAU—*Recherches nécroscopiques sur quelques altérations que subissent, après la mort, les vaisseaux sanguins, les poumons et la membrane muqueuse gastro-pulmonaire à l'état sain*, Archives Gén. de Méd., Tom. XII, (1826,) pp. 169 *et* 333. See also G. ANDRAL—*Précis d'Anatomie Pathologique*, Brussels, 1837, Tom. I, p. 327; and W. RAPP—*Annotationes practicæ de vera interpretatione observationum anatomiæ pathologiæ, præsertim ad morbos acutos spectantium*, Tubingen, 1834.

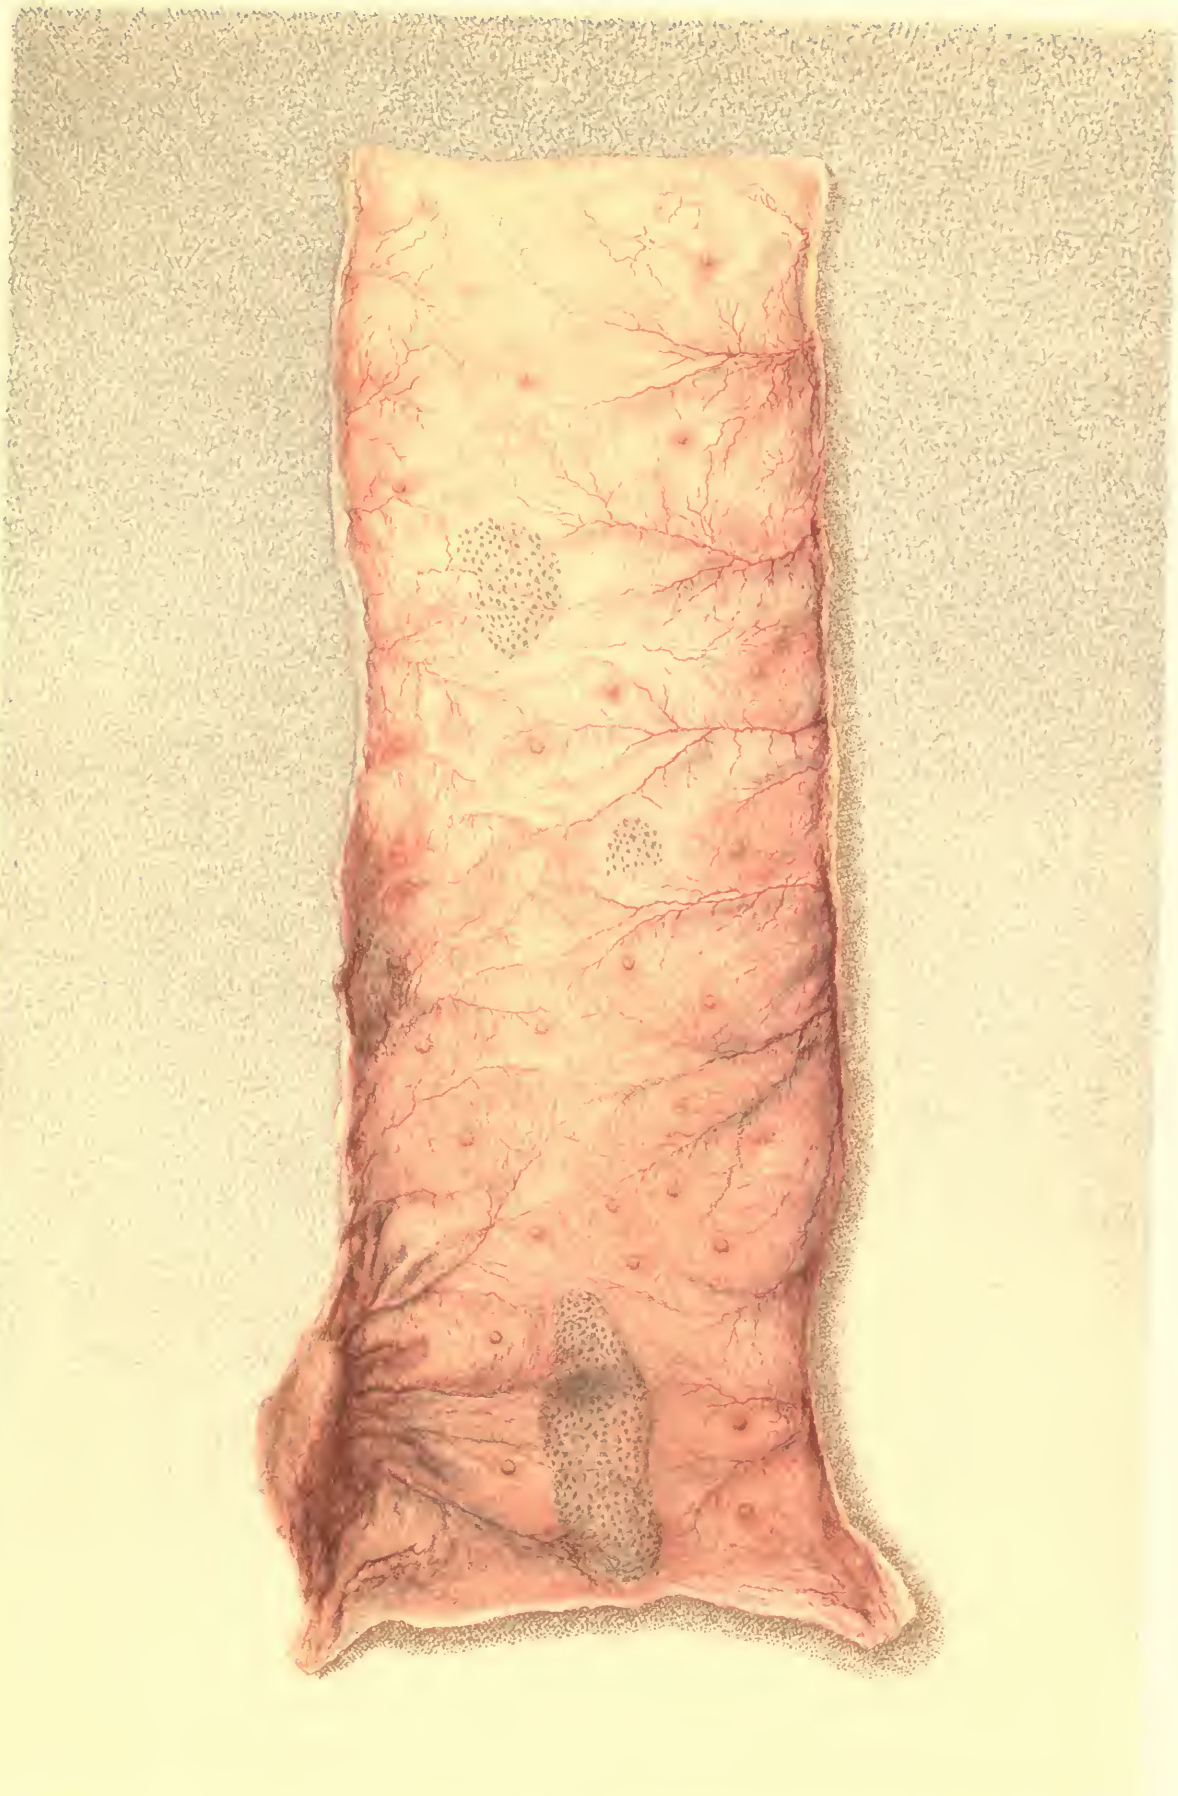
apt to be confounded with inflammatory softening than hypostatic congestion with inflammatory redness; and the intestinal walls may be exceedingly attenuated, as, for instance, from long-continued relaxation or paralysis of the muscular coat, without the slightest reason existing for believing that they have been inflamed. Microscopical examination of thin sections, whether cut extemporaneously after freezing, or more deliberately prepared after hardening the affected portion by suitable reagents, offers a more reliable method of making the discrimination, by exhibiting the presence or absence of the characteristic alterations to be presently described. By this method we shall not fail to be convinced that the reddened patches are very often to be regarded as merely hyperæmic, while in other instances they are undoubtedly inflammatory; and will find that the latter is almost always the case when the solitary follicles of the reddened patches are visibly enlarged, or in the case of the small intestine whenever the villi of the affected portion are visibly tumefied.

When the disease had lasted for several weeks, or when the patient had suffered from repeated attacks of diarrhœa before his fatal sickness, the bright-red color of the patches was replaced by the various shades of mahogany-red, brown, slate-color, or green, characteristic of chronic inflammation of the mucous membrane; and pigment deposits in the closed follicles were of frequent occurrence. Softening of the mucous membrane was, perhaps, more frequent in the chronic than in the acute cases. On this subject, however, I desire to speak with great caution, in view of the danger of confounding post mortem changes with morbid alterations, especially as I am satisfied that the inflamed mucous membrane usually undergoes putrefactive changes sooner after death than the normal. A still more striking lesion, sometimes observed in the chronic cases, was a progressive thickening in the submucous connective tissue, which in extreme cases became also brawny, inelastic and friable.

In the presentation of further anatomical details it will be convenient to consider, first, the conditions to be observed in the small intestine, and, subsequently, those encountered in the large.

Lesions observed in the Small Intestine.—When patches of inflammation were seated in the small intestine the villi of the affected portion were usually more or less tumefied. When this condition was well marked the surface acquired a plush-like appearance which was quite characteristic. With a lens it was easy to observe in these patches that many of the villi were club-shaped from the disproportionate enlargement of their extremities; others were elongated and thickened, but without marked distortion. The enlargement of the closed glands of the affected portion was generally more marked in the case of the solitary follicles than in the patches of Peyer. The latter were usually so slightly swollen as hardly to attract attention, even in cases in which the solitary follicles projected as little pin-head tumors above the surface of the mucous membrane; but the deposits of pigment already mentioned as occurring in the protracted cases, and in subjects who had suffered from previous attacks, were even more common in the patches than in the solitary follicles, and gave rise to characteristic appearances which were to be found in a large percentage of the autopsies made during the war.

The chromo-lithograph facing this page represents this very common condition, in which the pigment deposits remaining after former attacks complicated the appearances of the more recent process. The specimen was obtained from an autopsy made at the Judiciary Square hospital, Washington, D. C., Assistant Surgeon E. J. Marsh, U. S. A.,



surgeon in charge, and was brought immediately to the Museum, where the water-color drawing reproduced in the plate was made by Mr. H. Faber. The following very brief history of the case was furnished:

CASE 879.—Private Henry M. Pierce, company K, 25th Maine volunteers, was taken sick while with his regiment near Chantilly, Virginia, March 23, 1863. The diagnosis on the regimental register is simply "fever." Continuing to grow worse, he was sent to Washington and was admitted to Judiciary Square hospital, April 13, 1863. Diagnosis, remittent fever. The febrile symptoms were accompanied by diarrhœa, from which he had previously suffered several times. He did well under treatment, and was apparently convalescing, though the diarrhœa still continued to the extent of several stools a day, when pneumonia supervened and was the cause of death, May 11th. *Autopsy:* The lower portion of both lungs was hepatized. The greater part of the ileum presented the conditions exhibited by the specimen. The mucous membrane of the colon was darkly reddened, but no marked enlargement of the solitary glands of the colon was noticed.

The piece represented was selected from about the middle of the ileum. It will be observed that the general surface of the mucous membrane is of a reddish cream-color, becoming more distinctly red in the lower portion of the specimen. On this surface distended veins of a rich crimson color ramify in an arborescent manner. Three Peyer's patches are observable. The larger, situated in the lower part of the specimen, is an elongated ellipse about an inch and a half long by rather more than half an inch broad; a little over two inches above the upper extremity of this patch is the second, which is somewhat rounded and rather more than a quarter of an inch in diameter; an inch higher, and rather to the left, is the third patch, elliptical in form, three-quarters of an inch long and about as broad as the first. The first and largest of these patches is very slightly thickened, the others not perceptibly so; but in all the patches the follicles are the seat of bluish-black pigment deposits, giving them the "shaven-beard" appearance, which will be described hereafter. The solitary follicles are enlarged, and project above the mucous surface as yellowish pimples nearly the size of mustard seed, each of which is seated on a little circular reddened area. These enlarged follicles are most numerous in the lower part of the specimen. They do not contain any deposit of black pigment. The whole surface of the piece presented a somewhat plush-like texture, to which the plate hardly does justice, but otherwise the representation is quite accurate.

This specimen represents the condition of the mucous membrane of the ileum after it had been the seat of an inflammatory process of moderate intensity, but of several weeks' duration. As the patient had previously had several attacks of diarrhœa, it seems probable that the pigment deposits in the patches of Peyer antedated the last illness. The same may possibly be true, to a certain extent at least, with regard to the enlargement of the solitary follicles.

A chromo-lithograph, representing a portion of the ileum in a condition very similar to that just described, was published in my preliminary report in Circular No. 6, (Surgeon General's Office, 1865,) facing page 146. In that case, which will be given in detail in a subsequent chapter, the patient, private Lewis Sage, company A, 186th New York volunteers, died December 10, 1864, in the 3d division of the Alexandria general hospital, of a febrile disorder, which was recorded on the hospital register as typhoid fever. When brought to the hospital, ten days before death, he stated that he had suffered from diarrhœa for several months. On the autopsy the ileum was found in a condition very similar to that described above. The colon was ulcerated, especially at its extremities. In the transverse colon several of the ulcers were cicatrizing.

The plate now presented is rather more elaborately executed than that published in Circular No. 6, but either of them will serve to give a just notion of the appearances

presented by the inflamed mucous membrane of the ileum in subjects suffering with diarrhœa. A greater or less degree of redness and vascularity; greater or less tumefaction of the closed glands; occasional absence of any pigment deposit in Peyer's patches, or presence of a spot of pigment in each of the solitary follicles—these were the chief variations resulting from the varying duration and intensity of the disease.

When such preparations as those under consideration are immersed in alcohol for preservation the abnormal color speedily disappears; but if the closed glands are enlarged, or the villi hypertrophied, these conditions are well displayed, even when the pieces are long preserved, as may be seen in a number of specimens in the Army Medical Museum, some of which have already been described in Section III, while others will be presented in the next chapter. From the series I have selected two for photographic representation in this place. The first is from a case of diarrhœa of nearly two months' duration.

CASE 880.—Corporal George W. Stearnes, company I, 9th New Hampshire volunteers, was mustered into service August 15, 1862, to serve three years. There is no record of the time at which he was first taken sick; but he appears on the register of the general field hospital of the 9th Corps, near Harper's Ferry, Virginia, as under treatment for diarrhœa November 5th; sent to Alexandria November 12th. He is borne on the register of the convalescent hospital at Fort Ellsworth, near Alexandria, Virginia, admitted November 16th, general debility; no disposition recorded. The register of Fairfax Seminary hospital, near Alexandria, Virginia, shows that he was admitted to that hospital December 8th—chronic diarrhœa—transferred to Philadelphia, December 15th. He is borne on the register of the Satterlee hospital, West Philadelphia, admitted December 16th—chronic diarrhœa. December 23d, papers were made out for his discharge from service by reason of "great debility and emaciation, the result of chronic diarrhœa, which is still unchecked." Pending the approval of these papers by the proper authority, he died, December 24th, at 5 A. M. From the circumstance that his discharge papers were made out the day before his death it is to be presumed the fatal issue was unexpected. The autopsy was made during the afternoon of the same day by Professor Joseph Leidy, of the University of Pennsylvania, who forwarded the following statement to the Surgeon General's Office with the specimens: *Autopsy:* Age about 30. The body was rather emaciated. The chest and abdomen presented a number of faint spots of purpura. The brain was healthy. There were no pleuritic attachments, nor was there any pleurisy on either side. Lobular pneumonia was observed in the lower lobes of both lungs; the inflamed lobules were numerous—varied from the size of a marble to that of a walnut—and were in the stage of gray hepatization. Evidences of bronchitis were also observed. The heart was healthy. The stomach was exceedingly contracted. The liver was apparently sound; the gall-bladder enormously distended with green bile; the spleen small but healthy; the pancreas and kidneys sound. The intestines were inflamed throughout; in the small intestine the inflammation increased in intensity toward the ileo-cæcal valve; the agminated glands were slightly thickened and dark-red with inflammation; the solitary glands were enlarged, and looked like yellow mustard seeds sprinkled on a red ground. The large intestine was streaked and spotted with ash-color and dark-red on a nearly uniform red ground; there were also spots of ecchymosis, and the epithelium was softened.

Nos. 93 to 98, Medical Section, Army Medical Museum, are from this case. The specimens are six successive portions of the ileum. In Nos. 93 and 94 there are well-marked valvuli conniventes, and some hypertrophy of the villi, giving a velvety appearance to the surface. The solitary follicles are enlarged to the size of small pin-heads and project above the surface of the mucous membrane. In No. 94 there is a small Peyer's patch, which is a little more distinct than normal. In Nos. 95 to 98 there are no valvuli conniventes, no hypertrophy of the villi is observable, and the intestinal walls are thinner than normal. Each of these pieces presents a number of enlarged solitary follicles, which are most conspicuous in No. 98. In both 97 and 98 there is a slightly-thickened Peyer's patch. No portion of the large intestine was preserved.

The plate facing this page is a reproduction of a photograph of No. 98, which represents it of the natural size. This piece was taken from near the ileo-cæcal valve. Just above its middle is a thickened Peyer's patch, which appears as a dark elliptical spot two inches long by an inch in transverse diameter near its middle. This is crossed obliquely from above downwards by a wrinkle in the mucous membrane, produced accidentally by the method of preparing the specimen. The surface of the patch is not materially elevated above the surface of the surrounding mucous membrane, yet it is thicker than

Am. Photo-Relief Printing Co., *1012 Arch St., Philadelphia.*

ILEUM WITH ENLARGED SOLITARY FOLLICLES.

No. 98. MEDICAL SECTION.

normal, and, when examined by transmitted light, appears more opaque than any of the other patches observed in this subject. The enlarged solitary follicles are scattered over the rest of the mucous surface as little pimple-like projecting tumors, which are largest and most numerous in the lower half of the piece; the largest of them, however, do not exceed pin-heads in size. Owing to the tenuity of the mucous membrane, the course of the circular fibres of the muscular coat is plainly indicated by numerous transverse lines. For the same reason the arborescent branching of the blood-vessels is also indicated in several places.

In the specimen selected for the second illustration the villi are considerably hypertrophied, giving the surface a plush-like aspect. The patient died in the Third Division of the Alexandria general hospital after an illness of about a month. The following account of the case was forwarded to the Museum with the specimens by Acting Assistant Surgeon Wm. C. Miner:

CASE 881.—Private Erastus Boyd, company G, 195th Ohio volunteers; admitted July 29, 1865. Diarrhœa. [This man was mustered into service February 20, 1865, to serve one year. He appears on the hospital register of his regiment as "sick," July 27th; no diagnosis recorded. "Sent to general hospital."] At the time of admission the patient was feeble, his pulse weak, compressible, 80 per minute; tongue moist, slightly coated, its tip and edges clean. He said he had had diarrhœa for three or four weeks. July 30th: ℞. Blue-pill and opium, of each eight grains, extract of nux vomica two grains. Make eight pills. Take one every three hours. Brandy. Milk diet. July 31st: No change. August 1st: The symptoms have assumed a typhoid character; the tongue is black and dry, and delirium has set in. ℞. Chalk mixture four ounces, tincture of catechu one ounce, tincture of opium four drachms. Take a teaspoonful every three hours; also turpentine and tincture of cinchona. August 2d: Better. Continue treatment. August 3d: A good deal better; tongue moist; has had but four stools in the last twenty-four hours. August 5th: Still improving; begins to relish his food. Continue treatment. Died, suddenly, August 6th, having been up fifteen minutes before. The cause of death recorded on the hospital register was "typhoid fever." *Autopsy:* The only point which attracted attention was the condition of the intestinal canal. The solitary follicles throughout the ileum were enlarged, and there was slight thickening of the patches of Peyer, several of which presented one or more minute ulcers. The colon was closely studded with minute follicular ulcers about the size of pin-pricks.

Nos. 600 and 601, Medical Section, Army Medical Museum, are from this case. No. 600 is a portion of the ileum taken a few feet above the ileo-cæcal valve, and is the specimen selected for representation in this place. No. 601 consists of the last three inches of the ileum, with the ileo-cæcal valve and a portion of the cæcum. The ileum presents appearances very similar to those which will be described in connection with No. 600. The cæcum presents a number of the minute follicular ulcers mentioned in Dr. Miner's account of the autopsy as existing in the colon.

The plate facing page 302 is a reproduction of a photograph of No. 600, which represents it of the natural size. The mucous surface of the piece is marked by a number of transverse rugæ, which are the imperfectly-developed valvulæ conniventes. The hypertrophy of the villi gives the whole mucous surface a plush-like appearance which is exceedingly characteristic, and which can be studied advantageously with a lens. A number of enlarged solitary follicles the size of pin-heads project slightly above the mucous surface as rounded elevations. In the lower half of the specimen there is a Peyer's patch two inches and a half long by three-quarters of an inch wide at its broadest part. The position of this patch is plainly indicated by the absence of the transverse rugæ above referred to, which terminate rather abruptly at the margins of the patch. The surface of the patch, which is not materially elevated above the surrounding mucous membrane, is marked by irregular narrow transverse broken lines, on which are seated numerous hypertrophied villi similar to those of the surrounding mucous membrane; between these are narrow irregular areas on which there are no villi, and which, hence, appear somewhat depressed below the general surface. The general effect of this arrangement is to give the surface of the patch a somewhat reticulated appearance. At the center of the patch there

is a shallow oval ulcer an eighth of an inch in diameter. A little more than half an inch below this, near the right-hand margin of the patch, is another similar ulcer, and a third smaller one will be noticed at the upper extremity of the patch.

This specimen was selected, after an examination of the whole intestine, as fairly representing the condition of the Peyer's patches in this case. All of them appeared somewhat more opaque than natural when examined by transmitted light, but none were thicker or more prominent than the one represented in the plate. The large patch immediately above the ileo-cæcal valve, which is exhibited in No. 601, differs from that shown in the plate only in its outline; the appearance of its surface is precisely the same. In it, also, there is a single small ulcer similar to those shown in the patch of No. 600. None of the patches of Peyer in this case presented any larger ulcers than these, and in many of them there were no ulcers. Here, therefore, we have to do with a much less extensive disease of Peyer's patches than that which is characteristic of typhoid fever.

In the cases which furnished the specimens from which the three previous illustrations were taken the inflammatory process had lasted several weeks before death, and in two of them, viz: Pierce and Boyd, the patients had presented symptoms of fever, which, in the former case, was recorded on the hospital register as remittent, in the latter as typhoid, fever. The discussion of the interesting question of the relation of the lesion just described to a particular form of malarial fever must be postponed to a subsequent chapter; it must suffice at present to express the conviction that the intestinal lesion, in the class of fever cases referred to, presents nothing by which it can be distinguished from the lesions observed in other cases in which the febrile phenomena are not well marked, or at least present no specific characters. In the case of Stearnes, for example, the febrile phenomena were not such as to arrest attention, and the prominent features of the case were debility and emaciation. This case having lasted nearly two months before death, might, no doubt, deserve the designation "chronic diarrhœa," which was assigned to it on the register of the Satterlee hospital, but it differs in no essential respect from cases which terminated fatally in six or four weeks, or even in a shorter time. It will further be noticed that in all three of the cases just presented the large intestine was seriously affected as well as the small. In the case of Pierce, it is described as "darkly reddened;" in the case of Stearnes, "the large intestine was streaked and spotted with ash color and dark-red on a nearly uniform red ground; there were also spots of ecchymosis, and the epithelium was softened;" in the case of Boyd, the cæcum and colon were "closely studded with minute follicular ulcers about the size of pin-pricks." These instances may be taken as examples of the types most frequently encountered.

If to the numerous group of similar cases the yet more extensive group be added in which the condition of the small intestine just described coexisted with the follicular ulceration of the colon characteristic of the chronic forms of flux, or with the diphtheritic sloughs and ulcers of acute dysentery, it will be found that nearly all the cases of simple acute inflammation of the mucous membrane of the small intestine which were actually observed during the war have been included. Certainly, for myself, I must state that neither at the Army Medical Museum, nor in any of the autopsies I witnessed in the military hospitals during the war, did I ever encounter a single case of diarrhœa, whether acute or chronic, in which the small intestine alone was involved. It is true that a number of autopsies are recorded in the last section in which congestion, inflammation, or even

AND HYPERTROPHIED VILLI.

No. 600. MEDICAL SECTION.

LIBRARY
UNIVERSITY
CALIFORNIA

ulceration of the small intestine, or of some portion of it, is reported, without the statement that any morbid condition was observed in the large. But in the majority of these cases there is no record whatever of the condition of the large intestine; and I am of opinion that this circumstance almost always resulted, as I know by inquiry it did in some instances, from the fact that the medical officer making the examination was so fully impressed with the belief, which was referred to on page 266, that the lesions of diarrhœa were to be sought in the small intestine, that it was not thought worth while to examine the large.

The cases referred to may be briefly analyzed, as follows: In eighteen of them the small intestine is described as being congested or inflamed, while no mention whatever is made of the condition of the large intestine. Seven of these cases occurred in the third division of the Alexandria hospital, viz: Cases 467, 477, 478, 482, 488, 491 and 532; the others are cases 182, 597, 611, 699, 730, 751, 752, 769, 798, 799 and 821. In eight cases ulceration is affirmed to have existed in the small intestine, but the condition of the large is not recorded. Cases 102, 114, 416, 475, 476, 595, 596 and 831 come under this head. Of these, case 476 was doubtless one of typhoid fever, and cases 102 and 596 may possibly have been of the same nature, though the account of the autopsy is too imperfect to warrant a positive decision.

Besides these twenty-six cases characterized by the fatal omission to record the condition of the large intestine, there are four in which it is not explicitly stated that this portion of the bowel was examined, although the reader may perhaps infer that it was, from the language employed. These are cases 184, 224, 481 and 560. Case 184 was a chronic flux, said to have been of three months' standing at the time of admission to the hospital in which the patient died nearly two months later; it is reported that he "slowly sank." On the autopsy the brain was not examined. There were extensive pleuritic adhesions, "both old and recent," on the left side. The spleen was enlarged; the stomach slightly congested. "The small intestines presented numerous ulcers in the neighborhood of the ileo-cæcal valve. The remaining viscera appeared to be normal." Case 224 appears on the hospital register as "chronic diarrhœa;" but the patient stated, on admission to the hospital in which he died a week later, "that he had suffered from diarrhœa for a month." There were pleuritic adhesions, large heart-clots, and twenty or more biliary calculi. "The intestines had a healthy appearance, except about three feet of the lower portion of the ileum, which were inflamed but not ulcerated." In case 481, which had been recorded on the hospital register as "general debility" and "phthisis," the body was much emaciated; the thoracic viscera healthy, with the exception of pleuritic adhesions. "The abdominal viscera also appeared to be healthy, except that there was some ulceration of the mucous membrane of the small intestine." Case 560 appears to have been a severe case of acute diarrhœa in which the patient improved somewhat after he entered the hospital, but on the fifth day after admission "got up to stool, fell down suddenly, and expired in a few minutes." Nothing was found on the autopsy to account for the sudden death of this man. "The ileum was inflamed throughout, but no ulcers were found." The spleen was soft and dark colored; the kidneys somewhat congested. "All the other viscera normal." I cannot say that I am convinced, by the general statement with which the record of the autopsy concludes in cases 184 and 560, that the large intestine was actually examined, and the two others must also be regarded with a certain degree of doubt, since the expres-

sions employed would probably have been used had the small intestine alone been inspected. In this place, also, on account of its vagueness of statement, I would include case 470, in which it is recorded that "the mucous membrane of the ileum was softened and in several places deeply ulcerated. The large intestine was not materially diseased." The name of the observer is unknown, and it is not possible to judge what the exact condition of the colon really was.

There remain, however, six cases in which it is more expressly indicated that the large intestine actually was examined and no disease found, viz: Case 116: The patient "was convalescent from typhoid fever, but was still suffering from diarrhœa, and was much emaciated." He died suddenly. On the autopsy, pleuritic adhesions were found on the left side, and vegetations on the tricuspid and mitral valves. "The jejunum was intensely congested; the rest of the intestines was rather pale, but otherwise healthy." Case 291 is recorded as "chronic diarrhœa;" but no particulars are reported except the autopsy. Pleuritic adhesions were found on the left side; the liver weighed about sixty-four ounces; the spleen was softened; the kidneys large and fatty. The whole small intestine is described as being "thickened, but not ulcerated." "The mucous membrane of the ileum near the ileo-cæcal valve was softened. Peyer's glands were not inflamed, nor were any indications of inflammation observed in the colon." Case 484 is a fatal case of severe acute diarrhœa following measles. The lungs were found slightly congested; the liver and spleen somewhat enlarged. "The mucous membrane of the ileum was softened; that of the large intestine not materially altered." Case 725 is recorded on the hospital register as "chronic diarrhœa;" but no further particulars are reported except that the patient died, about three weeks after admission, of double pneumonia. On the autopsy, besides extensive hepatization of the lungs and enlargement of the liver, spleen, kidneys and mesenteric glands, "there were a few small patches of inflammation in the small intestine. The large intestine was healthy." Case 789 is recorded on the hospital register as "consumption." The patient "complained chiefly of the accompanying diarrhœa, which was troublesome and persistent." His body was greatly emaciated. "The lungs, pericardium and heart were glued together into a mass by firm adhesions, which were interspersed with tubercles of all sizes." The lungs were tubercular and contained numerous cavities. There was some redness of the lower part of the ileum. "The ileo-cæcal valve and the colon were apparently normal." Case 567 is recorded on the registers of two hospitals as suffering from "chronic diarrhœa." He died of pneumonia less than a month after entering the first of the two. On the autopsy, besides the pulmonary lesions, a fatty liver and enlarged spleen were found. "There was marked ulceration in the ileum for six inches above the ileo-cæcal valve; the rest of the small intestine was healthy. The large intestine was not inflamed or ulcerated." It would appear from the autopsy that the last of these cases was probably one of typhoid fever in which the patient was struck down by pneumonia during convalescence; it was common enough for fever cases to be registered as chronic diarrhœa. As to the five remaining cases, which, so far as I have been able to ascertain, are the only ones reported during the war which favor the opinion that the small intestine is the essential seat of the lesion in diarrhœa, the reader will not fail to note their similarity to the cases previously commented upon,* in which no lesion whatever was found in the alimentary canal. Supposing the

PEYER'S PATCHES.

Ileal [illegible] valve. Shaven beard appearance

observations to have been carefully made by competent observers, it would seem most probable that they belonged in fact to the category just alluded to. I am disposed to suggest this explanation of case 789; but, unfortunately, in the four remaining cases the medical officer by whom the autopsy was made is unknown, so that the degree of accuracy belonging to these observations must remain a matter of doubt.

Allusion has already been made* to the pigment deposits observed both in subjects who had suffered from several attacks of acute diarrhœa and in the chronic cases. In the small intestine these deposits occur especially in the solitary follicles, in the patches of Peyer, and in the apices of the villi. Diffuse pigment deposits in the mucous membrane also occur as greenish or slate-colored streaks or patches. These, however, are usually associated with the more localized deposits just alluded to, and as these are generally more intense than the diffuse pigmentation, they give the characteristic appearances to the specimen. The pigment deposits in the apices of the villi appear, on close inspection even to the naked eye, as innumerable dark points closely strewn over the whole surface of the affected portion of the mucous membrane, to which it gives a greenish or slate-gray tinge when viewed from a little distance. In the solitary glands the pigment deposits occur as dark dots in the centers of the glands, and the similar deposits in the patches of Peyer produce what has been designated as the "shaven-beard" or "shaven-chin" appearance.

The chromo-plate facing page 304 reproduces a water-color drawing by Mr. H. Faber from a specimen which exhibited this appearance. The piece was brought to the Museum during the summer of 1863 by Surgeon H. Crosby, U. S. volunteers, then in charge of the Columbian hospital, Washington, D. C., who stated that the patient had died of diarrhœa, and that no ulceration had been found in any part of the intestinal canal. All the closed glands of the ileum contained pigment deposits similar to those shown in the specimen, and the greater part of the large intestine resembled the portion of the cæcum here figured.

The plate represents the last four inches of the ileum, the ileo-cæcal valve and a small part of the cæcum. The general surface of the mucous membrane is of a yellowish-cream color, the hue being darker in the cæcum than in the ileum. This tint is variegated by some reddish discoloration and a moderate degree of vascular injection. Just above the middle of the portion of ileum represented, there is an oblong Peyer's patch an inch and a quarter long by three quarters of an inch wide, which presents the shaven-beard appearance. Above this are four much smaller patches of similar character. Below it, near the right edge of the piece, are two other patches in the same condition, one of them nearly three-quarters of an inch in long diameter, the other about a quarter of an inch. The general surface of the ileum between these patches and the ileo-cæcal valve is mottled with slate-color due to diffuse pigment deposits, and presents a large number of dark dots representing pigment deposits in the closed glands, which are so numerous in this region that perhaps the greater part of this discolored area may be described as an irregularly shaped Peyer's patch. In the cæcum a large portion of the surface is occupied by slate-gray streaks of diffuse pigmentation. The plate facing page 298, which represents the ileum in the case of Pierce, may be consulted as another illustration of the shaven-beard appearance, and the same may be said of the plate in Circular No. 6, facing page 146. Pigment deposits such as these are found in Peyer's patches which present no recognizable

* *Supra*, p. 298.

thickening, as well as in more or less thickened patches. In like manner they are found in solitary follicles of normal size as well as in those which are enlarged. Very often the deposit is found in both the solitary and the agminated glands, but not unfrequently the latter only are affected, more rarely the former alone.

Lesions observed in the Large Intestine.—The general description already given* of the appearances observed in inflammation of the intestinal mucous membrane applies, almost without modification, to those cases in which the inflammatory process is seated in the large intestine, and it is therefore unnecessary to repeat what was then said with regard to the characteristic changes of color and texture. Attention may, however, be drawn to the frequency with which the lesions found in any case are observed to be more pronounced in the cæcum and descending colon than in the intermediate tract, a circumstance which is also very noticeable in the case of follicular ulceration of the large intestine, as will be seen hereafter.

It will usually be observed, moreover, that when both the ileum and the large intestine are inflamed the process is further advanced in the latter than in the former, as though it had been seated primarily in the large intestine and only subsequently extended into the small. Thus mere reddened hyperæmic patches will often be found in the ileum, while in the cæcum and colon the slate-colored and greenish discolorations characteristic of chronic inflammation will be observed. Perhaps it is to some extent for this reason that in chronic cases the solitary glands of the colon are so much more frequently found ulcerated than those of the ileum; but I am inclined to believe, also, that the latter are more prone to ulcerate than the former, and that this is the chief reason why we so seldom encounter specimens in which the diseased solitary glands of the large intestine are as large as pin-heads without finding a tiny ulcer on the apex of each.

An inferior degree of enlargement of the solitary glands of the large intestine, in which, however, they attain twice their normal diameter, or even greater dimensions, is much more frequently to be met with; and that it is but seldom referred to in the autopsies in the last section must be explained by the fact that it is so easily overlooked. It has already been mentioned† that the enlarged solitary glands of the ileum are apt to project beyond the surface of the mucous membrane with constricted necks like tiny polypi; while in the large intestine the enlarged solitary glands are generally sessile. In fact, in the latter case the diseased glands find room up to a certain point to accommodate their increased bulk in the submucous connective tissue, which very often indeed increases in thickness while the closed glands are enlarging, so that glands as large even as pin-heads may produce only the most trifling elevation of the mucous membrane, and a smaller degree of enlargement may be quite invisible to the ordinary methods of investigation. When this is the case, however, the tumefaction of the closed glands can generally be detected at once by the unaided eye on examining the intestine by transmitted light, when the swollen glands become distinctly visible as minute opaque spots, while the surrounding tissue is quite translucent. In such cases it will often be found, on making perpendicular sections and examining them with a power of ten to twenty diameters, that the enlarged glands are three or four times their normal size. Unfortunately immersion in alcohol, by increasing the opacity of the intestinal walls, interferes with the distinctness with which the naked eye can recognize these moderate degrees of enlargement, and most of the specimens of this kind which were set aside at

TRANSVERSE COLON WITH ENLARGED GLANDS
ULCERATED AT THEIR APICES.

No. 820. MEDICAL SECTION.

the Museum for permanent preservation speedily lost all value except as material for microscopic examination. For this reason I am unable to present a photographic illustration showing a moderate degree of enlargement of the solitary glands as seen by the naked eye, though a photograph of a thin section as seen with the microscope will be presented a little further on. I have, however, selected for photographic illustration a specimen in which the solitary glands are enlarged to the size of bird-shot, but in which a little ulcer has formed on the apex of each, although the patient had been sick but a few weeks. The case was one of typhoid fever accompanied by a smart catarrhal inflammation of the colon:

CASE 882.—Private George Hayes, company B, 12th U. S. infantry; age 25; was sent to the guard-house at Russell barracks, Washington, D. C., May 10, 1866. He continued under the charge of the guard, but apparently in excellent health, until about August 1st, when he came to sick-call suffering with diarrhœa, and was excused from fatigue duty. Assistant Surgeon E. Bentley, post surgeon at Russell barracks, states that he had not been on sick report at any time previously. The diarrhœa continued in spite of treatment, and soon after symptoms of typhoid fever were recognized, and the patient was sent to post hospital. Acting Assistant Surgeon George P. Hanawalt reports that he was admitted to the post hospital, Washington, D. C., August 25th. On admission he was found to be quite stupid, though he could readily be aroused. The following prescriptions were ordered: ℞. Nitro-muriatic acid one fluid drachm, water six fluid ounces. Take a tablespoonful every four hours, alternating with the following: ℞. Carbonate of ammonia one drachm, oil of turpentine two fluid drachms, powdered gum Arabic half a drachm, cinnamon-water six fluid ounces. Dose, a tablespoonful every four hours. Beef-tea. On the afternoon of the 26th he became delirious, and during the night constant watching and restraint were required to keep him in bed. This continued until the forenoon of the 27th, when almost complete loss of sensibility ensued. The patient could not swallow the milk-punch which had been ordered in the morning. An attempt was made to give him beef-tea, but a teaspoonful of it almost strangled him. Heavy stupor continued until noon on the 28th, when he died. *Autopsy:* The arachnoid at the base of the brain was opaque, and there was some effusion of lymph on the posterior portion of the spinal cord just below the medulla oblongata. All the viscera appeared healthy with the exception of the intestinal canal. The solitary glands of both large and small intestine were greatly enlarged and ulcerated at their apices, and there was considerable thickening and ulceration of the patches of Peyer. The intestinal canal was forwarded to the Army Medical Museum by Assistant Surgeon William Thomson, U. S. A., surgeon-in charge of the post hospital.

Nos. 815 to 821, Medical Section, are from this case. Nos. 815, 816 and 817 are successive portions of the ileum, in which Peyer's patches are much thickened and ulcerated; the villi are greatly hypertrophied. In Nos. 815 and 816 the solitary glands are enlarged to rounded tumors, many of them as much as a fifth of an inch in diameter, or even larger, and some of them, especially in No. 816, ulcerated at their apices. In No. 817 the enlarged solitary glands have the same character, but are much less numerous. No. 818 consists of the last inch of the ileum, with the ileo-cæcal valve and cæcum. Both the ileum and cæcum present a number of enlarged solitary glands similar to those above described; those in the cæcum are ulcerated at their apices. No. 819 is from the ascending, No. 820 from the transverse, and No. 821 from the descending colon; all present enlarged solitary glands ulcerated at their apices, similar to those shown in the plate representing No. 820. These little tumors in No. 819 are smaller, in No. 821 larger, but in both less numerous than those in No. 820.

The plate facing page 306 is reproduced from a photograph of No. 820, which, as just mentioned, is a portion of the transverse colon from this case. The numerous enlarged glands vary from one-tenth to one-fifth of an inch in diameter, and project from the surface as small sessile tumors. The ulcers vary from little circular dot-like depressions to more irregular excavations one-tenth of an inch in diameter. The mucous membrane is nowhere ulcerated or abraded except on the summits of the enlarged glands.

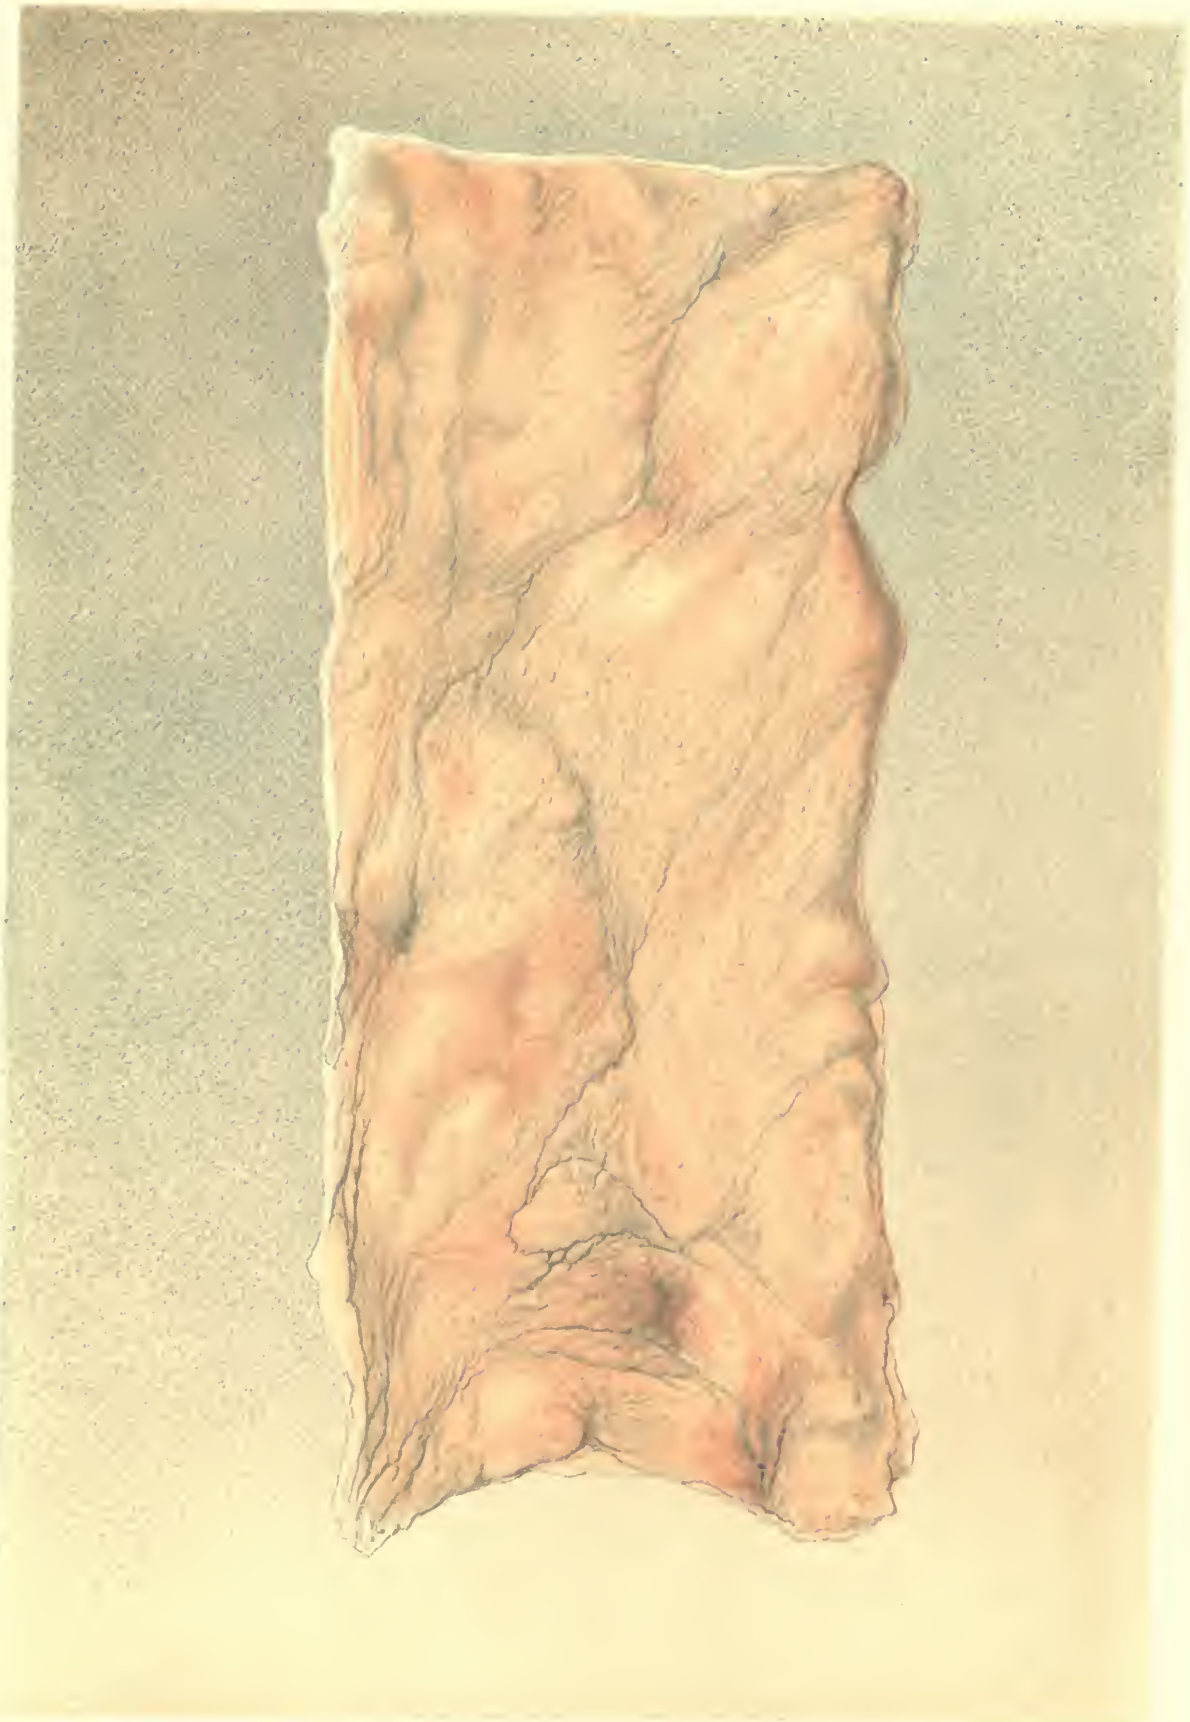
As this patient died of typhoid fever, the case might have been reserved for the chapter which treats of that disease to illustrate one variety of the intense catarrhal inflammation of the colon, which so frequently accompanies it; but I have preferred to

present it in this place, both because it differs only in the degree to which the glands are enlarged from the similar condition which occurs in simple acute diarrhœa, and because it illustrates the rapidity with which ulceration takes place when the solitary glands are enlarged in inflammations of the large intestine.

The pigment deposits encountered in the large intestine of those who have suffered from repeated attacks of acute diarrhœa, or from a protracted flux, may be seated as diffuse patches on the general surface of the mucous membrane, or may be more especially localized in the closed glands. The diffuse form of these deposits is more frequently encountered in the large than in the small intestine, and is apt to be more intense in the former, producing darker and more extensive discolorations; hence the ash and slate-colored, greenish and blackish streaks, which are so frequently observed in the cæcum, colon and rectum. The more localized deposits of pigment in the solitary glands are, on the other hand, less common in the large intestine than in the small; a circumstance which probably depends upon the fact that the ulcerative process, which it has been shown is so prone to occur in the large intestine, primarily destroys the centres of the closed glands, and therewith the usual seat of the pigment deposit. Still, cases are not infrequently observed in which the closed glands of the cæcum and descending colon, or even of the whole large intestine, are blackened with pigment, appearing as little blue-black dots about the size of grains of black pepper pretty plentifully scattered over the surface of the mucous membrane. Numerous examples of this condition might have been selected for pictorial representation; I have, however, preferred to reproduce a somewhat less frequent variety, which I have several times noticed, in which the central dot of pigment is surrounded by a tiny ring of the same color

CASE 833.—Private Julius Zinke, company G, 98th Pennsylvania veteran volunteers; age 54; was mustered into service March 5, 1864, to serve three years. He had previously served out a three years' enlistment which had just expired. The register of the field hospital of the Second Division, Sixth Army Corps, reports him admitted November 23d; catarrh; returned to duty December 1st. It appears from the company muster-rolls, however, that he was again taken on sick-report and sent to general hospital in Washington, December 14th. It appears from the case-book of the Douglas hospital, Washington, D. C., that he was admitted to that hospital December 16, 1864, suffering with diarrhœa, said to be of a month's standing, and with some cough. The diarrhœa yielded to treatment, and he was furloughed, returning to hospital about April 1, 1865. At that time he stated that his diarrhœa was quite well, but that he suffered much pain in the region of the heart, running back to the angle of the scapula. He was somewhat short of breath, anæmic, and had a dry, hacking cough. The action of the heart was strong and rapid, and a murmur was distinctly heard coincident with the first sound; this murmur was so loud that it could be heard all over the region of the organ, which was evidently enlarged. He stated that he had suffered from trouble in the region of the heart for two years, during which time, however, he had been able to do duty in the field, carrying his knapsack. During the three weeks preceding his death he did not seem to suffer very much, but had a continual slight pain in the region of the heart, a short, dry cough and some dyspnœa; the action of the heart was rapid but regular. He was up and about the ward every day, and did not need to have his head very much elevated in order to sleep. On the morning of May 9th he was suddenly seized with a sort of spasm; his breathing became very short and spasmodic, and the action of the heart intermittent. This lasted for about half an hour, when he quietly expired. *Autopsy* fifteen hours after death: Rigor mortis well marked. The heart was somewhat enlarged. Just above the semilunar valves of the aorta there was an aneurismal sac capable of containing about two ounces of fluid. The sac had burst, the blood making its way between the middle and external coats of the aorta to a point a little above the left auricle, being prevented from communicating with the pericardial sac by a copious deposit of lymph, which, however, was so soft that it was torn during the examination, thus making the communication complete. The mitral valves were somewhat thickened and rough; the aortic valves large but healthy; the aorta slightly atheromatous. The pericardium was firmly adherent to nearly the whole surface of the heart and could be removed with difficulty. The apices of both lungs contained calcareous deposits and other indications of obsolete tubercle. The mucous membrane of the colon was somewhat softened; its solitary follicles all prominent and distinct, with a central spot of black pigment in each; just around each follicle was an areola of black pigment. The other organs were healthy. Acting Assistant Surgeon David L. Haight. The specimens were forwarded to the Museum by Assistant Surgeon Wm. F. Norris, U. S. A.

Nos. 546 and 547, Medical Section, Army Medical Museum, are from this case. No. 546 is the heart and a portion of the aorta, presenting the aneurism above described. No.



LIBRARY
UNIVERSITY OF
CALIFORNIA.

547 is a portion of the descending colon, in which, by transmitted light, a few of the solitary follicles can still be discerned in the alcoholic preparation as opaque spots; most of them, however, have become invisible to the naked eye.

The chromo-lithograph facing page 308 is from a water-color drawing representing the appearances presented by this piece of colon in the recent state; in the lettering of the plate the word dysentery has been erroneously used. The surface of the mucous membrane is salmon-colored, with greenish streaks due to diffuse pigment deposit. In many places the vessels can be discerned as delicate red arborizations. Each of the solitary glands is marked by a central dot of pigment surrounded by a little pigment ring. Nos. 642 to 650, Microscopical Section, are a series of perpendicular cuts of this colon, and will be described further on.

It will be observed that in this case the diarrhœa from which the patient had suffered had not troubled him for some time before death, so that the specimen represents a period when the inflammatory process was well advanced towards resolution. Doubtless slight anatomical lesions such as these—an undue degree of vascularity, abnormal pigmentation, and a moderate degree of enlargement of the closed glands—remaining behind after an attack of diarrhœa are among the conditions which render those who have suffered from that disease more liable to be again attacked, if exposed anew to the causes of the disease, than healthy persons under similar circumstances.

Analysis of cases in which the lesions described above were observed.—The number of cases recorded in Section III in which the large intestine only was the seat of the processes described is not large. In a few of the cases that appear to belong to this category the record shows that the small intestine was healthy, or at least not perceptibly diseased; as for example, cases 111, 118, 202, 324, 330, 361, 364, 386, 605, 749, 783 and 845. Of these some were of brief duration, as cases 111, 330 and 386; the others were more protracted. Case 783 was one of dysentery. Case 111 appears to have been one in which a very limited inflammation in the transverse and descending colon extended through the walls of the intestine to the peritoneal coat and involved a portion of the omentum. The symptoms are described as "resembling those of typhoid fever." Among the more protracted cases No. 202 may be particularly noticed. The patient had become much emaciated, and about ten days before death pus was recognized in the anterior chamber of the right eye. Nothing abnormal was observed in the small intestine except that the jejunum was discolored with bile. The large intestine was thin, its mucous membrane in regions congested and of a rich purple color.

In a small number of other cases, while the evidences of inflammation are recorded as having been observed in the large intestine, the condition of the mucous membrane of the small intestine is not mentioned, so that it must remain a matter of doubt whether this portion of the alimentary canal was affected. Cases 109, 136, 185, 305, 465, 480, 483, 493, 496, 503, 590, 635, 690, 694 and 796 belong to this category. Of these, cases 185 and 590 were examples of acute dysentery. In case 190 it is expressly stated that the large intestine only was examined. Case 465 is reported on the hospital register as one of "continued fever." In case 483 there was "great constriction and thickening of the large intestine at the sigmoid flexure, diminishing its calibre to about one-fourth its natural diameter." In case 493 the colon was contracted throughout its whole length to about half an inch in diameter.

But in the great majority of the cases included in Section III in which it is recorded that the large intestine was congested or inflamed without being ulcerated, the small intestine also, especially the ileum, was more or less extensively involved. I note altogether one hundred and twenty-five cases of this kind, viz: Cases 103, 113, 121, 124, 126, 128, 130, 131, 133, 135, 137, 144, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 162, 165, 170, 171, 172, 175, 177, 179, 209, 212, 217, 218, 222, 230, 232, 241, 280, 282, 287, 288, 294, 299, 303, 328, 331, 335, 337, 342,* 345, 347, 348, 352, 353, 359, 360, 366, 376, 377, 385, 397, 399, 412, 415, 419, 435, 442, 444, 445, 446, 460, 466, 473, 474, 479,† 489, 492, 494, 495, 497, 498, 512, 517, 525, 534, 537, 538, 544, 546, 547, 548, 551, 554, 556, 558, 562, 581, 583, 599, 603, 625, 639, 642, 644, 668, 672, 689, 692, 701, 716, 760, 761, 763, 776, 780, 785, 788, 797, 805 and 809.

Of these cases 121, 562, 780 and 805 were cases of acute dysentery. In some of the others, as for example, cases 103, 241, 328, 581, 639 and 776,‡ the histories clearly show that the diarrhœa had been of such duration that it must fairly be designated as acute. In others, as for example, cases 177, 218, 230, 232, 303, 360, 466, 473, 497, 556, 642 and 672, it is clearly shown by the record that the patient suffered from diarrhœa from five months to a year, or even longer, before death, so that the disease must undoubtedly be designated chronic. But in the majority of the cases, owing to the absence of any regimental record, the duration of the disease before the patient was admitted to general hospital cannot be ascertained, and it is therefore impossible to group all of them as acute and chronic, especially as no importance can be attached to the distinction between acute and chronic cases as recorded in the hospital registers, since patients who were very sick with any form of flux were commonly entered as suffering with chronic diarrhœa, without much inquiry into the actual duration of the disease; indeed the same was often done in the case of patients suffering with acute diphtheritic dysentery, if admitted during the third or fourth week of the disease, or later. It will be found, however, that in about three-fourths of the cases under consideration the recorded hospital history of the patient does not exceed three months; indeed, in rather more than half it does not exceed two months, varying from a few days to that period.

Among the autopsies embraced in this series are twenty-five by Professor Joseph Leidy, of the University of Pennsylvania, in cases of the so-called Chickahominy diarrhœa. To this group belong cases 124, 126, 128, 130, 131, 133, 135, 137, 144, 146,§ 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 162 and 175. The patients were almost all admitted to Satterlee hospital, West Philadelphia, from the Army of the Potomac at Harrison's Landing, Virginia, on or about August 10, 1862, and died at various periods, from a few days to two or three months subsequently, with the exception of case 162, in which life was protracted to four months, and case 175, in which the patient survived rather more than six months after admission to hospital. In most of these cases the

* In case 342 the existence of ulcers in the small intestine, especially in Peyer's patches, is recorded. I understand from the description that these were similar to those represented in the plate facing p. 302.

† In case 479 it is also stated that the lower part of the ileum was coated with "a pruloid exudation," probably merely muco-pus.

‡ Case 776 is one of considerable interest. The patient is reported to have suffered from typhoid (?) fever followed by rheumatism and debility. Three months after his first admission to hospital, and during the month preceding his death, he had several more or less imperfect paroxysms of what was supposed to be intermittent fever, for which quinine was rather freely administered. During the night preceding his death he was attacked with diarrhœa, and died suddenly next day. Since the case was put in print in this work (see p. 240 *supra*) my attention has been called to the fact that the reporter, Dr. H. M. Lyman, has published it elsewhere as a case of congestive fever. (American Med. Times, August, 1862, Vol. V, p. 110.) I am not disposed to dispute this view of the case, but the interest of the autopsy in connection with sharp diarrhœa of brief duration is not thereby diminished.

§ In case 146, which resembles the rest of the series in its general features, it is stated that one of the inflamed patches of the ileum, about three inches long, was gangrenous, the gangrene extending to the peritonæum.

length of time the patient had been ill before reaching Satterlee hospital is not recorded. The exceptions are cases 147, 153, 158 and 159. In case 147, the regimental records show that the patient was taken sick with "fever" June 3d; was treated in division hospital, convalesced, and was returned to his regiment, where he was again taken on sick-report July 6th, the diagnosis this time being scurvy; the date at which his diarrhœa commenced, however, is not recorded. In case 153, the regimental records show that the man was first taken on sick-report with diarrhœa about two weeks before his admission to Satterlee hospital. In case 158 the regimental records represent the patient as first taken on sick-report with diarrhœa July 31st; August 5th, the diagnosis "remittent fever and incipient scurvy" is recorded, and August 10th he was admitted to Satterlee hospital. In case 159, the regimental records represent the patient as excused from drill July 24th, and taken on sick-report with diarrhœa July 29th. He was admitted to Satterlee hospital August 10th. These examples show that a portion at least of the cases under consideration had been sick but a short time before they reached Satterlee hospital; others no doubt had suffered with diarrhœa for several weeks or even longer before they were sent away from Harrison's Landing, so that the series represents cases of various duration from a few weeks to more than six months. The relation of these cases to malarial fever, indicated by the record of Nos. 147 and 158, will be discussed in a subsequent chapter.

It is to be remarked that the term Chickahominy diarrhœa, as used at the time, embraced not merely such cases as those above referred to, but all the forms of flux, including chronic cases, which had progressed to thickening and follicular ulceration of the colon, as well as cases in which the diphtheritic dysenteric process was developed before death, and cases complicated with ordinary enteric fever. This is well illustrated by the autopsies made by Professor Leidy on the bodies of diarrhœa patients admitted to Satterlee hospital from Harrison's Landing at the same time as those enumerated above. Thus, case 134 is characterized by well-marked thickening and follicular ulceration of the colon, while cases 138, 139, 140, 142 and 145 represent transition forms between this condition and that just described. Cases 132, 143, 160 and 161 are instances in which the diphtheritic process was developed in the colon with more or less intensity, and in case 141, besides colon ulcers such as occur in diphtheritic dysentery, the ulceration of Peyer's patches characteristic of enteric fever was observed. Nevertheless, if we may form a judgment from Professor Leidy's autopsies, it must be admitted that in the majority of the Chickahominy cases the inflammation of the intestinal mucous membrane did not progress to the stage of ulceration.

It must, however, be remarked further that cases quite similar to these occurred, not only in the Army of the Potomac after it left the Peninsula, but in the other armies also, in all parts of the country and at every period of the war. Professor Leidy himself has contributed several interesting autopsies—cases 165, 170, 171 and 172—on patients sent to Satterlee hospital from the Army of the Potomac after it left the Peninsula, in which the lesions observed were quite similar to what was found in the Chickahominy cases.

This general distribution of the class of cases under consideration gives additional value to Professor Leidy's autopsies, which constitute by far the most important contribution to the pathological anatomy of the non-ulcerative form of intestinal inflammation made during the war. But a number of excellent observations of similar character have also been contributed by other medical officers. Thus, Assistant Surgeons George M. McGill and Har-

rison Allen, U. S. A., have each reported several well-observed cases from Lincoln hospital, and individual cases of a similar character, reported by various medical officers, will be found among those enumerated above as belonging to the group under consideration. Unfortunately, in very many of the cases included in this group the autopsies were very imperfectly recorded, but it is hoped that, imperfect as they are, they will serve to indicate the comparative frequency of fatal cases of diarrhœa without ulceration.*

In some of these imperfectly recorded cases it is merely stated that the mucous membrane of more or less of the small and large intestines was congested, as in cases 103, 113, 209, 412, 534, 547, 558, 583, 625 and 668; congested and softened, as in cases 287, 466, 603, 689 and 692; congested and thickened, as in cases 121, 218, 294, 397 and 809; or congested and contracted, as in cases 212 and 217. In other cases it is simply recorded, without further detail, that the mucous membrane was inflamed, as in cases 124, 179, 241, 328, 442, 446, 538, 546, 548, 551, 554, 556, 760 and 797; inflamed and softened, as in cases 299, 473, 474, 672 and 761; inflamed and thickened, as in cases 177, 444 and 544; or inflamed, softened and thickened, as in cases 280, 435 and 805.

* Corroborative testimony will be found in most of the few accounts of the appearances observed in the fatal cases of camp diarrhœa which were published in the American medical journals during the civil war. Thus, ALONZO CLARK is reported—American Medical Times, May, 1863, p. 210—to have exhibited to the New York Pathological Society, November 26, 1862, several specimens of intestines from soldiers who had died in Bellevue hospital of chronic diarrhœa contracted in Virginia. "When the first cases of this diarrhœa had presented themselves, he expected to find the same lesions after death which had characterized the chronic diarrhœa contracted by our soldiers during the Mexican war, viz., ulcerations of the mucous membrane. He was, however, very much surprised to find that such was not the case. The mucous membrane, in the majority of instances, presented an abraded appearance, as if an acid matter had been applied with a brush, only removing the epithelial scales. All the intestines examined gave an irregular and extraordinarily red injection, and in several instances there had been observed spots of ecchymosis in the colon. In one specimen there were noticed slight ulcerations in the mucous membrane of the large intestine, mostly in its upper portion, each spot being surrounded by a layer of lymph." He had made ten autopsies, and promised further details at a subsequent meeting. These particulars were communicated to the same society in December—The Medical and Surgical Reporter, January, 1863, p. 312. Eleven autopsies were now reported. In five of them no ulceration was found in any part of the intestinal canal. In these cases "the mucous membrane was thinned as by an acid; congestion was abundant, not of an arborescent, but of an ecchymosed appearance." In one of the six remaining cases there were a few ulcers near the rectum; in another, a few near the upper extremity of the colon. "The ulcers vary in degree, but in none of them are they very numerous. Some of them presented spaces overspread with lymphy matter. In these cases there was no ulceration, but the follicles presented dark spots giving a mottled appearance. The mesenteric glands are enlarged in all the cases. Peyer's patches are elevated and mottled over with dark spots, so that the mucous membrane presents a grayish appearance." These results are very similar to those which LEIDY had previously obtained in Philadelphia. I regret that Dr. CLARK has not published his observations in detail. They are not contained in the *Transactions of the New York Pathological Society*, Vol. I, New York, 1876. HENRY W. COOKE, house physician, Bellevue hospital, in the following February, published—*The Diarrhœa of Soldiers*, American Medical Times, February, 1863, p. 102—some additional observations, in which, however, those reported previously by CLARK appear to be included. Of 132 cases of this disease admitted October 3 and 5, 1862, 45 had proved fatal, and 17 autopsies had been made. "The duodenum and upper portion of the jejunum have usually been healthy, occasionally more or less congested. The inferior portion of the jejunum and all the ileum have, without exception, presented tracts of congestion at irregular intervals, varying in number and intensity; frequently points of extravasation were presented, but never of ulceration. Peyer's glands have been found invariably enlarged and thickened, of a grey color, the free surface presenting innumerable minute black points, each of which appeared to mark the situation of a diseased glandule. The mesenteric glands have, without exception, been found enlarged and prominent. The lesions of the large intestines have been either those of congestion, with varying degrees of extravasation or of ulceration, more or less extensive. The colon in the former cases has invariably presented patches of intense congestion, and in numerous instances extravasation, the amount and intensity varying in different subjects; in a few, the whole mucous surface of the intestine having a livid red color, in others, tracts of more or less intense congestion, at irregular intervals, as in the small intestines, would be noticed. The ileo-cæcal valve almost invariably presented intense congestion. The rectum has uniformly presented intense congestion, with more or less fibrinous exudation. Frequently the presence of fibrinous exudation was a question of doubt." Then follows a description of the cases in which ulceration was present, to which I shall recur hereafter, followed by the remark: "Of the seventeen examinations made, seven were more or less freely ulcerated, the remaining ten presented no ulcers." Surgeon J. R. BLACK, 113th Ohio volunteers, writes to The Cincinnati Lancet and Observer, Vol. VI, 1863, p. 424, that in a number of fatal cases of camp diarrhœa in General C. C. Gilbert's Division, Army of Kentucky, the ileum and colon always gave evidences of active inflammation, but "I have seen no ulceration." Assistant Surgeon D. A. WENDELL—*Post-mortem examinations of Cases reported on the monthly report of sick and wounded at Base hospital, 18th Army Corps, for the month of July*, 1864. Communicated by Assistant Surgeon C. E. MUNN, 27th Massachusetts volunteers, Boston Medical and Surgical Journal, Vol. LXXI, 1864, p. 113—reports the post mortem of private Daniel Jackson, company K, 5th U. S. colored troops, who died of camp diarrhœa. On opening the abdomen evidences of peritonitis were observed. The mucous membrane of "the cæcum, colon and three feet of the ileum were inflamed. No ulceration was discovered, but the mucous membrane in the region of the cæcum, about twelve inches either way, was found congested and thickened. About twelve inches of the rectum was also much inflamed. The mesenteric glands and the glands of the colon were somewhat enlarged." This case was reported to the Surgeon General's Office, together with a number of other autopsies, chiefly surgical, by Surgeon H. B. Fowler, 12th New Hampshire volunteers, in charge of the hospital, in a sub-report to his monthly report of sick and wounded for July, 1864. This sub-report was filed in the Surgical Section of the office, and the case was hence overlooked in preparing Section III. Surgeon GEORGE D. WINCH, 42d Wisconsin volunteers—*Chronic Diarrhœa*, Chicago Medical Journal, Vol. XXII, 1865, p. 344—relating his experience with this disease during the war, says that he never found the stomach diminished in size even in protracted cases; its mucous membrane was generally dark-red, but seldom softened or ulcerated. The duodenum and jejunum sometimes exhibit inflammatory appearances, but generally nothing decisive. In the ileum these appearances increase in intensity from the beginning to the ileo-cæcal valve. "The mucous membrane is of a dark or reddish-brown color and thickened. The vessels seemingly injected to their utmost fulness. The solitary follicles and agminated glands participate in the enlargement; but we have not succeeded in finding ulcers." The mucous membrane of the colon is of "a dark-red color, thickened, the solitary follicles enlarged. In some cases there is no ulceration to be found, and I confess I cannot diagnose this class from those in which on examination are found large ragged ulcers." In the majority of his cases, however, he found the colon ulcerated. Fatty liver was common; the kidneys in some cases enlarged and bloodless; the mesenteric glands were enlarged. The pericardium often contained from two to four ounces of fluid.

Even among the cases in which the appearances of the intestinal mucous membrane are more definitely characterized, all mention of the condition of the closed glands is very frequently omitted; so that the number of instances in which it is recorded that the closed glands were enlarged, or contained pigment deposits, or presented both these conditions, cannot be regarded as in any way indicating the comparative frequency with which these glands were thus affected. Moreover, as disease of the closed glands of the colon, when it does not progress far enough to produce ulceration, is usually less conspicuous than the similar lesion in the small intestine, it is not surprising that the latter was more frequently recorded than the former.

I note that in cases 131, 165 and 342 it is stated that the solitary glands in both large and small intestines, and the glands of Peyer in the latter, were enlarged; in cases 148, 222, 517 and 537, that the solitary glands were enlarged in both large and small intestines; in case 776, enlargement of the solitary glands in the large intestine only is recorded; the enlargement of the glands of Peyer and the solitary glands of the small intestine in cases 133, 172, 348 and 377; of the solitary glands of the small intestine only, in cases 126, 150, 153, 154, 155, 157, 162, 335, 347, 359, 492, 639 and 644; of Peyer's glands only, in cases 147 and 353. In cases 126, 147, 148 and 342 the enlargement was associated with deposits of pigment in the closed glands. Pigment deposits in the closed glands were also found in a number of cases in which no enlargement of the glands is recorded. It is stated that these deposits existed in the glands of Peyer as well as in the solitary glands of both large and small intestines in cases 130, 135, 137, 144, 153, 156 and 170; in the glands of Peyer only, in cases 159, 335 and 366; in the glands of Peyer and solitary glands of the small intestine, in case 151; in the glands of Peyer and solitary glands of the large intestine, in cases 128, 150, 155, 158, 162 and 175, and in the solitary glands of the large intestine only, in cases 149 and 154. I may note in this connection cases 342 and 347, both observed by Assistant Surgeon George M. McGill, U. S. A., in which it is recorded that the duodenal glands were somewhat enlarged. It is not clear, however, from the record in these cases, whether the reporter intended to indicate the racemose glands of the duodenum, or whether his attention was merely directed to an enlargement of the closed glands, which exist here as well as in other parts of the small intestine.

In some of the cases it is recorded that the diseased large intestine was contracted so as to be diminished in calibre, as for example, in cases 152, 156, 171, 377, 445, 489 and 492; in a few others the same condition is stated to exist in the intestines generally, as in cases 157, 232, 331, 494 and 498. In some of these cases, as in 331, 445, 489, 494 and 498, it is stated that the walls of the contracted intestine were thickened. The process by which the intestine becomes thickened and contracted will be described hereafter in connection with the chronic cases. It very generally results from a hyperplasia of the submucous connective tissue, which is usually, but not always, associated with ulceration of the solitary glands when it affects the large intestine.

Intussusceptions of the small intestine are recorded in several of these autopsies, as in cases 156, 157, 185, 494 and 639. In some instances a single intussusception was observed, in others several—(three in case 494, four in case 156.) They were not attended by any evidences of strangulation of the intestines or of local peritonitis, and are probably to be regarded simply as phenomena of the agony.

Besides cases 111 and 146, in which, as already mentioned,* the inflammation, for an area of a few inches, involved all the coats of the intestine, including the peritonæum, evidences of general *peritonitis* were occasionally observed, as in cases 171, 209, 241, 415 and 760. There were also a few instances in which it is recorded that the abdominal cavity contained more or less serum, as in cases 222, 554 and 809. Peritoneal adhesions, the result of former local peritonitis, were observed between the convex surface of the right lobe of the liver and the diaphragm in cases 137, 144 and 785; similar adhesions between the convex surface of the spleen and the parietal peritonæum in case 130. In case 554, (a colored soldier,) extensive tubercular disease of the *omentum* is recorded.

In fatal cases of diarrhœa, produced by the intestinal lesions just described, it very often happens that no lesion of the *stomach* can be recognized after death. Not unfrequently, however, this organ is involved in the catarrhal process, and evidences of hyperæmia, or of acute or chronic inflammation, such as punctiform or uniform redness, or other discoloration, with or without softening, thickening, &c., were observed. Thus the stomach is spoken of in some of the autopsies as being more or less extensively congested, as in cases 282, 347, 348, 352, 361, 445 and 809; congested and softened, as in cases 287, 345 and 353; inflamed to a greater or less extent, as in cases 133, 144, 146, 147, 149, 151, 152, 158, 177, 512, 556, 716, 749 and 805; inflamed and softened, as in cases 148, 150, 153 and 761; inflamed, softened and thickened, as in case 280; or even ulcerated, as in cases 551, 785 and possibly 605. There are also a few instances, as cases 294, 399, 465, 474 and 496, in which the stomach is simply spoken of as softened; but in view of the frequent occurrence of softening as a post mortem change in this organ, no great importance can be attributed to these observations.

Lesions observed in other organs.†—Although in many of the autopsies just discussed the lesions existing in other organs than the alimentary canal are not related with satisfactory detail, still enough has been recorded to furnish some interesting testimony with regard to the more frequent and more important complications. The cadaver was usually emaciated to a degree which varied with the duration of the disease and the severity of the symptoms. In the more protracted cases the emaciation was often extreme. Purpura-like blotches were occasionally observed on the skin of the trunk and extremities. From my own personal observations, as well as the verbal testimony of others, I am satisfied that they existed much oftener than would appear from the record.

The cranial cavity was very frequently not opened, but, when examined, the *brain* was generally found to be healthy. Occasionally the quantity of subarachnoidal fluid was greater than normal, as in cases 412 and 776; or the meninges appeared to be more or less congested, as in cases 202, 347, 348, 353, 460 and 761. In cases 175 and 415 meningitis was observed; in case 337 a small quantity of pus was found in the ventricles of the brain.

In case 359, observed by Assistant Surgeon Harrison Allen, U. S. A., suppuration of both *parotid glands* was observed; this case had been regarded as one of typhoid fever, but after death only the characteristic evidences of catarrhal inflammation of the mucous membrane of the ileum and large intestine were observed, and "Peyer's patches were normal."

* See pp. 309 and 310.

† The following remarks refer to the more important lesions recorded in one hundred and fifty-six autopsies of non-ulcerative inflammation of the mucous membrane of the intestinal canal, viz: Those enumerated on pages 309 and 310, and four of those selected for pictorial illustration, viz: Cases 879, 880, 881 and 883. Case 882 is not included, partly because of the existence of numerous ulcers, but chiefly because the case is one of undoubted typhoid fever.

The *respiratory organs* were very generally examined and were frequently the seat of some intercurrent inflammation. Occasionally diphtheria was the immediate cause of the fatal issue, as in cases 152, 170, 377 and 386. Bronchitis was a much more frequent complication; but doubtless the evidences of this inflammation frequently escaped observation, and the number of instances in which the record shows that simple bronchitis existed is comparatively small. Cases 361, 364, 415, 419 and 760 may be cited as examples. Intercurrent pneumonia and pleuropneumonia, if not of more frequent occurrence, were at least more frequently recognized during the autopsies. Thus it appears that pneumonia of the right lung existed in cases 136, 137, 175, 303, 446, 460, 692, 761, 796 and 809; of the left lung, in cases 230, 282, 330, 348, 517 and 583; of both lungs, in cases 149, 202, 209, 352, 360, 376, 385, 412, 581, 635, 639, 879 and 880. Pleuropneumonia of the right lung was observed in cases 155, 445 and 503; of the left lung, in cases 150, 217 and 716; of both lungs, in cases 162, 165, 353, 377, 399, 672* and 749. In a few of these cases the record clearly shows the presence of lobar (croupous) pneumonia in the stage of red or gray hepatization; in others it is equally clear that lobular pneumonia was present; but in many of the cases it is not possible to decide from the record what form of lung inflammation existed.

Œdema of one or both lungs was noticed in cases 157, 366 and 763. In case 337, the lower lobe of the right lung presented "a number of small irregular vomicæ containing a puruloid fluid," and the right pleural sac contained "about a pint of dirty yellowish liquid." More or less extensive tubercular disease of the lungs, with or without intercurrent pneumonia, or pleurisy, was found in a number of cases. The right lung only, appears to have been involved in cases 103, 158, 212, 294, 359, 525, 556, 605, 642 and 690; the left lung only, in cases 232, 397, and 446; both lungs in 113, 151, 172, 331, 345, 495, 534, 537, 538, 548 and 644. In case 525, which is in several respects a peculiar one, the posterior part of the cricoid cartilage was necrosed and surrounded by a collection of pus.

Pleurisy, without pneumonia or tubercular disease of the lungs, was not a very frequent complication, but was occasionally encountered, as in case 625, in which "both pleural sacs contained serum mixed with pus, and a large amount of pus adhered to the surface of the lungs," and in cases 222 and 554, in each of which the right lung was compressed by a large quantity of serum accumulated in the right pleural sac. In very many of the cases, however, the existence of pleuritic adhesions is recorded.

The *heart* did not usually present any very marked abnormity. It is occasionally spoken of as very small, as in cases 217, 460, 512 and 625; small, as in cases 605 and 797; soft and small, as in case 534; wasted, case 149; pale, case 359; pale and flaccid, case 113; pale and flabby, case 209; flabby, cases 150, 172 and 558; soft and flabby, case 809; large and flabby, case 788; enlarged and fatty, case 689. These expressions would appear to indicate the existence, in some cases, of a more or less pronounced atrophic condition of the organ, and should be considered in connection with the cardiac debility often observed during life, especially in chronic cases.

Valvular disease of the heart was occasionally observed, as in cases 158, 280, 625, 785 and 788. In all these examples the mitral valve was either exclusively or chiefly affected. In three of them—158, 785 and 788—there was effusion of serum into the pericardium. In case 883 there was an aneurism of the aorta.

* In case 672 both pleural cavities contained serum and pus and the right lung was hepatized, but the condition of the left lung is not stated.
